Concrete was mixed on the surface, spouted to a 4-in. pipe hung in the shaft by means of a wire cable, down which is flowed to a deflection box which shot it behind the forms. The pipe hung free in the shaft so that it was easy to pull it over from one side to the other, and thus to discharge the concrete wherever desired. Behind the forms the concrete was thoroughly spaded into place assuring a thorough mixture of the aggregates that may have become partially segregated during the long journey down the pipe.

Practical Pointers For Electrical And Mechanical Men

Deep Hole Drilling by Use Of Sectional Steel Rods

Much prospecting is now being done with rock drills and sectional drill steel. In 1916 a large western mining company drilled a 45-ft. horizontal hole by using 2-ft. sections of rod made from 1½-in. pipe; one piece being welded to a regular drill shank, the remaining sections having pipe threads on both ends. The necessary sleeves were provided for coupling the rods together as in ordinary pipe fitting, with the exception that the threads were cut to permit the pipe meeting end to end. Bit ends were threaded to fit the sleeves.

Later diamond-drill rod was used instead of pipe, and a water-connection swivel employed to introduce water directly into the rod, rather than through the rock-drill as previously, for it was found necessary to use rather high and direct water pressure to expel the cuttings from the deep drill holes.

Where hard rock was encountered it became necessary to use still heavier rod. The diamond-drill rod was abandoned and regular 1½-in. hollow round drill steel used in its stead. To maintain the maximum section of the drill steel, it was necessary to upset each end of the rod to 2 in. in diameter and machine a taper male thread on one

Fig. 2.—Swivel Used in Drilling Deep Holes

This swivel is part of the equipment used with drifting machines. When drilling deep holes, a thrust bearing is added to the swivel.

end with a corresponding female thread on the other. The rods were screwed together and in use they proved to be satisfactory mechanically, although the high-carbon drill steel was threaded in a lathe only with difficulty.

PRESENT DRILLING PRACTICE

The present equipment conforms closely to that used in standard mine practice and consists of a rock drill, 3-in. single screw columns, arms and saddle, 1-in. air hose, ¾-in. water hose, drill bits, threaded drill rods, sleeves and water-connection swivel. These items, except the last three, are standard mine equipment.

The column should be placed so as

to put the arm 4 ft. from the collar of the hole; this permits of a full 3-ft. run and allows room for the swivel. A good rigid set-up is markedly advantageous. The machine is then mounted in the conventional manner, except that as no water is passed through the machine, the water tube has been shortened by 2 in. and the common water spud is replaced by a plug. The water hose is connected to the water-connection swivel. A bit end is screwed into the swivel and drilling begins. The steel should be kept in alignment with the hole during the first 8 or 9 ft. of drilling. After the bit end is run out, the independent rotation on the machine is reversed and the joint unscrewed by the rotation mechanism, the bit end remaining in the hole. The machine is then cranked back and a 3-ft. drill rod is held between the swivel and the bit end in the hole and screwed up by the independent rotation running in its normal direction.

Drilling proceeds in this manner until the bit becomes dull, whereupon the clamp of the saddle is loosened, the machine turned to one side and the rods withdrawn and disconnected. The second (3½-in.) bit end is screwed into a sleeve on a 6-ft. rod and placed in the hole. Additional 6-ft. rods are added until the bit reaches the end of the hole. Drilling is resumed, and 3-ft. rods are added as the hole progresses; when the second bit becomes dull, the change is repeated.

To date the breakage of drill rods has been almost negligible, but fishing tools have been developed whereby a broken section in the hole may be withdrawn.

In drilling holes slightly above the horizontal to a depth of from 50 to 75 ft., water under 70-lb. pressure will eject the cuttings satisfactorily, but when drilling deeper holes or holes below the horizontal, higher pressures must be used. These may be obtained by tapping the pump column, if there is sufficient head in the shaft, or by the use of a small high-pressure pump.

Fig. 1—How the Drill Joints Have Changed

From a simple pipe joint and sleeve coupling a new joint has been designed which makes the work of adding another section easy.

From 3 to 5 gallons of water per minute are required, depending upon the pitch of the hole and the hardness of the ground. When gravelly ground is encountered, it is sometimes necessary to blow out the holes, although this is not often required with 50-ft. holes drilled above the horizontal.

Care should be taken in coupling the rods to insure each rod meeting its fellow end to end. The sleeves are not expected or designed to transmit the energy which flows directly through the drill rods. This brings up the question, how the energy from the piston hammer is transmitted to the drill bit.

One hole was recently drilled to a depth of 227 ft. All the steel and couplings shown were used in the hole at one time and as the rods and couplings weighed about 900 lb., it is obvious that the entire rod was not moved by each blow of the 14-lb. piston hammer but rather that a flow of high-frequency vibrations was transmitted through the rod and was expended by the action of the drill bit against the rock. This is borne out by the fact that the drilling speed per minute on the

last 50 ft. of this deep hole was practically the same as on the first 50 ft., the slowest rate of drilling being between the 75 and 100-ft. points.

Sectional drill rods can be used for purposes other than prospecting, particularly the draining of water courses and old workings ahead of development faces. Open-cut mining in quarries using deep holes will probably present a field for the new method.

It must be borne in mind that the depth of hole that can be drilled is limited by certain factors, the principal one being the wear on the gage of the drill bits, for it is evident that if each bit can drill but 1 ft. and only seven changes are available, the result would be a 7-ft. hole. However, under favorable conditions, 6 ft. or more can be drilled with each bit and, this being the case, deep holes can be drilled quite cheaply. The application in each individual case is a matter that must be decided by the mine management.

H. R. DRULLARD,
Engineer.
Denver Rock Drill
Manufacturing Co.,
Denver, Col.

Get a Competent Engineer And Follow His Advice

Small coal companies which do not have elaborate organizations, too often accuse the engineer of being extravagant, set in his ways, and disposed to subordinate practice to theory. Almost every coal man admits that he needs civil engineers for underground surveying and map making, although there are still those remarkable souls who will stoutly maintain that they can set centers better with the naked eye and will continue to adhere to their judgment until their rooms run together and their entries fail to meet.

The mechanical or electrical engineer also has his moments of extreme popularity, usually when his knowledge is required to solve some difficulty which has suspended production. When the mine once more is running smoothly, should he suggest that something be purchased or done to prevent the recurrence of the trouble, he is likely to be informed that he is extravagant. The fact is that coal operators, in general, do not utilize their engineers properly when they have them.

ADVICE HAS SOUND BASIS

Whatever else one may say about the engineer he rarely makes a recommendation without having some basis of fact for his advice. The "practical" mining man often buys a piece of equipment because he runs into a persuasive salesman, or because it looks good, or more often because he has successfully used the product of the same manufacturer at another operation, although conditions at that plant may have been entirely different.

Reflect a moment on these facts. How many mine locomotives are selected after a study of the duty cycle disclosing the necessary weight, drawbar pull and speed needed to handle a certain number of cars per trip, and trips per day? How many cutting machines are chosen with cutter bars and cutter chains geared for a certain speed, so

as to cut with the utmost efficiency the coal in which they are going to be used? How many mine fans are selected according to the actual volume of air required to be moved against the water gage as determined by a study of the actual resistance of the airways which they must ventilate? How many pumps are selected to meet definite conditions of capacity, head, etc., and are installed with proper pipe lines to give maximum efficiency?

One hundred per cent of our coal-mine equipment ought to be selected only after the facts mentioned above have been ascertained and considered. As a matter of fact, far less than 100 per cent of the machinery is thus selected, and the reason why conditions are not worse can be traced directly to the fact that a great percentage of the machinery belongs to a few large coal companies who fully realize the importance of proper selection.

A large part of the trouble with electrical equipment is that it has been poorly selected for the work it has to do, though most of the equipment that is being built today is capable of giving real service when properly applied.

Certainly in these days of enlightenment no coal operator need deny himself the privilege of actually knowing definitely what to expect from each piece of machinery he purchases or the satisfaction of being sure that under the circumstances he has made the right decision. If he would only realize it, careful selection and specification of machinery is the coal operator's protection against loss. Such care in selection would tend to make manufacturers more aggressive and would soon put off-standard products out of business, for there would be no sale for such material.

Many coal operators have been in business for years and really have never learned how to get efficiency out of their equipment. There are classes of machinery capable of being utilized to great advantage by the coal industry which nevertheless most operators

view with disfavor simply because they were never given a fair chance.

The centrifugal pump is one of these. Where it can be used, a centrifugal pump possesses the advantage of low first cost, low cost for upkeep, economy of space and under certain conditions comparatively high efficiency. Furthermore, it is easy to say definitely, when a few facts are known, whether under certain conditions a centrifugal pump will prove satisfactory. Nevertheless, some operators are afraid of this equipment, and many operators condemn it because they have been unable to force this sensitive machinery with its definite limits of performance to accomplish something physically impossible, though a rather rudimentary investigation would have made its proper function clear.

To cite a specific instance: A certain well-known and extremely capable coal operator was managing some mines for a large corporation in Pennsylvania, where there were some centrifugal pumps which had evidently been improperly applied. They never worked well and were taken out and scrapped and replaced by reciprocating pumps. This man firmly resolved never to have anything to do with a centrifugal pump.

Later he moved to West Virginia. In one of the mines under his control was a pumping problem that gave much trouble. A certain body of water had to be kept down to a certain level to prevent it from flooding haulage roads. A reciprocating pump was being used and was extremely expensive as it was continually breaking connecting rods, crosshead guides, etc., as well as wearing out valves and water cylinders. As the pump was out of commission much of the time it always fought a losing battle with the water.

CENTRIFUGAL PUMP MORE EFFICIENT

The operator was finally persuaded to replace this reciprocating unit with a centrifugal pump, which was carefully selected and properly installed. The result has been that with a pump, which cost about the same or less than the water end of the old pump, about three times as much water has been moved with only a 50 per cent greater expenditure of power. For a period of two years there has been practically no upkeep cost. About two hours was all that was necessary to figure out, check up, and make proper specifications for the pump to be used in this case.

If a company pays for advice it should test it at least once, and then if it does not give satisfactory results, stop paying for it. The engineer has a definite function in coal operation. With his education and experience and with his technical societies and publications to keep him up to date, he is bound to have a more complete knowledge of the subjects in which he specializes than anyone else. The operator should encourage the engineer to keep adding to this knowledge, and then when he needs it he should take advantage of it, realizing that he cannot himself efficiently fulfill his general functions and at the same time keep at his finger tips the details necessary to every branch of his work.

E. D. KNIGHT.

Charleston, W. Va.

Production And the Market

Inactivity Persists Throughout Coal Markets; Output at Low Level; Prices Still Falling

Inactivity is the prevailing condition in the coal markets of the country. From week to week there is little noticeable change either in demand or price, the general tendency being downward. The condition of the market is rather strikingly indicated by the bids received April 18 by the U. S. Shipping Board at New York for 1,065 gross tons of bituminous coal of either Pool 9 or 71 quality, the quotations ranging on a f.o.b. mine basis as low as \$1.03 per net ton. Several railroads have signed up for fuel supplies for the coming year, but the closing of industrial contracts still leaves much to be desired, these consumers seeming to buy only for immediate requirements. There is no demand for tonnage for lake movement, and every indication points to a late start of the shipping season.

As the possibility of a strike of British coal miners grows more remote another possible source of business to the American coal producer is fading like a mirage. Nevertheless, one of the few bright spots in the trade was the export activity at Baltimore last week. On April 16 and 17 32,190 tons of cargo coal was loaded there for foreign countries and the total shipments during the first eighteen days of the month were only 2,000 tons less than those of the entire month of March. Italy continues to be the largest purchaser, with France second.

Coal Age Index declined 3 points to 169 as of April 21, the corresponding price being \$2.04. This compares with \$2.08 on April 14.

Demand for Steam Grows in Midwest

In the Middle West the demand for steam coal seems to increase a little each day, but the shortage of screenings consequent on the lessened production has not been sufficient to force prices up. Otherwise Midwest trade shows little perceptible change. Running time

is low in all the Illinois fields, contracting being dull and the railroads still well fixed with supplies.

Demand is lacking from practically all sources in the Kentucky markets save for little buying by railroads, which are taking some tonnage to storage when they are not busy. Prices, however, are fairly firm all along the line. Northwestern markets seem to have hit the very bottom, sales and shipments from the docks being practically at a standstill. There are 3,250,000 tons of coal on the docks, of which 1,700,000 tons is free coal; the remainder is under contract but has not been accepted. Prices apparently are unchanged, but it is rumored that there is list cutting to obtain orders, so that another cut it likely. Stagnation reigns at Milwaukee. As the deadlock in wage negotiations continues at Kansas City, surplus coal supplies in the Southwest are nearing exhaustion, several large producers having ceased to quote prices. Warm weather has caused a slump in business in the Rocky Mountain region.

Ohio Markets Sink Further in Depths

Production in all Ohio fields is falling steadily with a continued lowering of demand, business at Columbus and Cleveland being lifeless. The market for slack at Cincinnati is better, but smokeless prices have softened. Pittsburgh has one of the dullest periods in its history except during a strike. Buffalo reports a slight improvement. Business is uniformly light throughout the New England and Atlantic seaboard markets from Boston to Birmingham.

Production of bituminous coal took a further drop of 84,000 tons during the week ended April 12, when 6,742,000 net tons was produced, according to the Geological Survey. Anthracite output was 1,856,000 net tons, an increase of 308,000 tons over the preceding week.

Estimates of Production

(a) Revised from last report. (b) Subject to revision. (c) Minus one day's production to equalize number of days in the two years.

Midwest Wants Only Steam

The coal trade of the Midwest shows little change during the week, even though the demand for steam sizes grows a little each day. The shortage of screenings certainly will have to make itself markedly felt on the market some time soon with production as low as it is in every field, but that effect has not been strong enough yet to push prices high. Southern Illinois screenings have not yet climbed above \$2.25. Much of that size brings only \$2.10 and \$2.15. One restraining influence is the Kentucky coal available at so much lower prices. However, the amount of this is much reduced by the April 15 strike in western Kentucky. Stocks of coal in striking Kansas are about exhausted, thus slowly removing another small competitor.

The Midwestern fields are getting very little running time and not enough big contracts have been made since April 1 to improve this situation. A few small contracts are about all that have been definitely sewed up yet, for railroads still have heavy tonnages on the ground and are dallying. In southern Illinois even the 50c. undercutting of the association operators by the independents and by the Jackson County and Du Quoin group of operators does not produce any spot-market business, so coal simply will not move at any price. Nearly all mines are idle.

Mt. Olive district mines are getting a day or two a week but they cannot move lump at \$2.85 when Franklin County can be had for a little less. Railroad tonnage in this field is fairly good, however. The Standard field, as usual, is in the worst position of all the Illinois fields. Crushers are working on lump that will not sell at \$2.25, so as to move the coal as screenings at \$2.

The spring lull has hit St. Louis and everything is practically at a standstill. Some yards did not move one load out in the three first days of last week. The public is not buying early storage coal and there is no demand for current needs. Wagon load steam has practically dropped off entirely on account of a large number of plants using electricity for power and needing no heat. Country domestic demand has practically ceased, excepting a little for anthracite chestnut. Judging from the way operators are going after this business there is plenty of anthracite. Country steam is reported fairly active at points.

Kentucky Trade Is Slow

The general situation in Kentucky is anything but satisfactory to operator and jobber, due to lack of demand from all sources. Retailers are stocked to supply immediate demands, and with mild weather are not in the market. Industrial consumers, utilities, byproduct and other heavy

Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines	1924		1923	
	April 21	April 14	April 7	April 23
Index	169	172	171	231
Weighted average price.....	\$2.04	\$2.08	\$2.07	\$2.79

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913-1918," published by the Geological Survey and the War Industries Board.

takers appear to be buying only immediate requirements. There has been just a little railroad buying, however, as the Southern Ry. and a few others are starting to take a little tonnage and move it to storage when they are not busy.

Prices are quite firm all along the line. Western, Kentucky screenings are now quoted at the mine-run basis, while nut has advanced to \$2@2.25 a ton. Large prepared such as egg, lump and block are slow, as there is no material market for these sizes, but the small stove size has a good Southern movement in the summer, and screenings are needed by consumers using automatic stokers. Early opening of lake movement is not expected by the coal trade, as the ice is late in getting out of the lakes and there is no demand in sight.

Northwest Dull as Can Be

The soft-coal market at the head of the lakes seems to have reached a period of inactivity from which there hardly can be a change for the worse. Docks are selling little or nothing and shipments are at a standstill except for the coal which railroad companies are taking out to enable the docks to work a few days a week, and so keep their crews together.

Official announcement of stocks on docks shows that there are now 3,250,000 tons of soft coal on the docks, of which 1,700,000 tons is free coal. The balance is under contract but has not yet been accepted. Prices are the same as far as coal men will admit, but it is whispered that one dock is cutting below list to obtain a few orders, and it is probable that another cut may come. To add to the pessimistic outlook it is predicted that there will be a 30-per cent cut in

the ore output this year, which will mean less coal sold to the independent mining companies. For this reason the mining companies are not in a hurry to start operations and are not placing orders for fuel.

The coal market at Milwaukee continues flat and stale. Little is doing in either hard or soft coal. The latter is weak and almost unsaleable because of the promised May reduction. The cut of \$1 to \$1.50 per ton at the head of the lakes adds to the disinclination to buy at present prices. The weather continues warm, and the domestic coal-burning season is about over.

Little Doing in the West

While representatives of Southwestern district operators and miners in conference in Kansas City are deadlocked over a wage contract, surplus supplies of coal are being exhausted. Several large producers have ceased to quote prices. Jobbers are handling the product of some mines, independent of the operators' association, the operators of which have signed contracts renewing for three years the wage scale which expired April 1. For such coal of the Southwestern district as is available, the price remains unchanged. Kansas lump is \$4.50; nut, \$4; mine run \$3.50 and screenings \$2.50.

Warm weather throughout the Rocky Mountain region caused a considerable slump in the Colorado coal market during the past week. A number of additional mines among the less lucrative have been closed for the season. The mines worked on an average of about half time last week, the operators reporting about 28 per cent of the time lost on account of no market.

Mines in Utah are working about two days a week. Industries are buying little. The domestic demand is for slack, egg, nut and stove coal. The large sizes have become a drug on the market. There are many "no bill" cars of lump and domestic lump on the tracks just now. The labor situation is excellent and prices on small sizes remain firm.

Ohio Markets Still Sagging

Production continues to decline steadily in all Ohio fields. Demand for coal in the Columbus market has declined further, and with the continued reduction in demand throughout the state operators are closing down until market conditions improve. As a result loadings in the southern Ohio field have fallen below 10 per cent of capacity. Only a few operations having steam contracts or railroad fuel agreements are operating. Eastern Ohio is somewhat better off, but the output in that section is being reduced radically. Domestic trade is practically dead. Pocahontas is not in as good demand as formerly and Ohio-mined grades are dead. Steam business, which usually is the backbone of the market at this time, also is flat. There is practically no steam contracting, as users are buying what they desire in the open market. Railroad contracts have now been closed, and in most cases at extremely low quotations. There is now less distress coal on the market than was the case two weeks ago. Only occasional inquiries for lake contracts are heard and practically no contracting has been closed.

An appreciable betterment in the market for slack and softening in prices of smokeless are the high lights of the Cincinnati market. The slack situation was to have been expected but the other is not so easy to trace. For several weeks the demand for the residue has been a little stronger than production, and with the gradual clearing up of distress coal, it was only logical that screenings should be a little harder to get. Generally speaking the free movement is on a \$1 basis, though there are some off grades from Kentucky that are selling 10 to 20c. cheaper. The big spread in the price of run of mine and block coal still continues. Here and there there is an inquiry for 2-in. coal for lake shipment, but the full swing of this business has not started. River business has been cut down appreciably through the stoppage of mining in the K. & M. fields of the Kanawha district. Specialized coals are quoted as follows: Block, \$2.75@3.25; egg, \$2@2.50.

The "no market" situation, accompanied by 100 per cent transportation facilities throughout the country, and the lighter shipping of lake cargo coal due to the heavy stocks at the head of the lakes, has brought about extreme heaviness in the Cleveland market. Large consumers are still drawing upon stocks and the buyer who enters the open market at this time to supply his needs is not of such sig-

nificance as to have any salutary effect whatsoever upon the market. Inquiries for fuel are scarce and the negotiation of contracts for current coal year requirements are negligible.

The Pittsburgh market is perhaps the dulllest on record, except for strike periods. Line consumers are buying scarcely any coal, depending on stocks and expecting lighter consumption. The steel industry has slowed down 10 per cent from the rate in early March. The lake season still lags. The lake shippers do not seem to be doing much even in the non-union fields.

Business at Buffalo is somewhat better, though some of the confirmed pessimists assert that the improvement is only in spots and that the general trade is unchanged.

New England Reports Light Trade

Only light tonnages are being placed in New England. Sales are confined for the most part, however, to relatively small lots forced on the market by factors who are obliged either to move demurrage coal or make room for arrivals. There are signs that this practice is less in vogue than a fortnight ago, and minimum prices are less heard from.

The Hampton Roads market shows the same indications. The volume of No. 1 and No. 2 grades on wheels has been reduced and spot prices are being more closely held at \$4@ \$4.25, depending upon grade. Certain of the agencies say now that no No. 1 Navy Standard coal can be bought at less than \$4.25 per gross ton f.o.b. vessel, and that statement probably is accurate as of this writing. In other words, there seems to be a firmer intention on the part of operators to curtail, and if held to long enough this policy would of course be effective.

All-rail from central Pennsylvania there is no material change. An increasing number of producers are determined not to mine coal at prices below the dead line. Money lenders are naturally encouraging this attitude, and while the way to improved conditions is an uphill road for the present it is clear that only by a close-hauled policy on the part of a large number of mine owners that present extremely low prices can be eliminated. A considerable tonnage of railroad fuel has been placed during the past fortnight or two at prices ranging from \$1.60 to \$1.75 per net ton, f.o.b. mines. The railroads generally will make a large saving on coal purchases during the current season.

Seaboard Markets Dull but Hopeful

Less coal is coming to the New York tidewater market. The average daily number of cars at the local terminals during the week was about 1,250, compared with about 2,000 a few weeks ago. While the market is draggy and dull there are some bright spots discernible. With free coals shortening and consumers reluctant to part with their reserve stocks there is a feeling that conditions will improve gradually. Reports from northern New York indicate more industrial activity with increased consumption. The local tidewater market showed a little more strength toward the week, both as to demand and prices.

Trade at Philadelphia is dull, but hope still persists that it will improve, though there are no signs that it will very soon. The one pleased person in the entire trade is the consumer, who feels that he has the upper hand now and can replace much of the stock that he is burning up at less than it cost him. Yet even this is no inducement for prompt filling in of the gaps that he is making. Spot prices are unchanged, and even though the same prices have ruled for

months the buyer seems to think that they may go even lower.

Little change is noticeable at Baltimore except for a marked renewal of activities for export movement. Despite restriction of production in a number of the fields, under agreements and otherwise, the supply at this point seems to be keeping up with the demand, which is exceptionally light.

Extreme dullness prevails in West Virginia with spot buying at the minimum and the bulk of loadings for contract delivery. As a result there has been a material curtailment in both high- and low-volatile fields and many mines are idle. The only improvement affecting smokeless mines has been at tidewater, due largely to curtailed shipments from the mines to the piers. Foreign inquiries are more numerous, largely as a result of a discussion of British labor troubles. Prices at the piers have steadied a little, but they are still unusually low.

Coal buying is lagging in the Birmingham market, inquiries coming in slowly and comparatively little new business being booked, either in steam and domestic grades. It seems difficult to interest consumers to the extent of stocking, little reserve supply being carried in any quarter. Contracting is still in its early stages, consumers apparently being of the opinion that there is no cause for special hurry to provide for future requirements. Spot sales of domestic sizes are light, contracts having been entered into by the principal dealers. Little distress coal is in evidence.

Anthracite Demand Below Expectations

While domestic sizes of hard coal are moving in good volume there is no rush. Dealers are taking their quotas of company coal and the larger independent operators are moving their tonnage without difficulty, but the smaller mines are not finding business so easy. Demand is not up to expectations. The easy winter and the knowledge that the miners are working under an agreement that will not terminate until next year have made the consumer indifferent. Even the fact that present prices are only for the month of April has no effect on buyers. Stove coal leads in activity, closely trailed by egg, with chestnut bringing up the third position. Call for pea coal is fairly good. The continued strength of barley coal is the feature of the steam market. It is in good demand and together with rice is moving steadily. Buckwheat drags along slowly. Unseasonably cool spring weather at Philadelphia and Baltimore has helped the sale of domestic sizes in those cities, but steam coals are in a bad way.

Connellsville Coke Market Stagnant

The Connellsville coke market reflects the decreasing activity in the steel trade in general and the extreme stagnation of the pig-iron trade in particular. Production of beehive coke during the week ended April 12 was 266,000 net tons, according to the Geological Survey, a decline of 12,000 tons as compared with the previous week.

Foreign Market And Export News

Improved Outlook in British Coal Market; Colliery Output Rebounds

Operators and consumers are still having their difficulties in the Welsh market, though with an improved outlook for settlement of the miners' wage controversy there has been a slight slackening in demand. Most of the collieries are still heavily booked and have not yet caught up in deliveries. Buyers are fairly well stocked with supplies and the recent surplus of waiting vessels is less in evidence.

Home consumers are taking large quantities of coal so that in all there is little available for shipment abroad. There is considerable pressure for prompt supplies and prices are firm.

Heavy demands are being made by domestic consumers on the Newcastle market, especially for gas coals. Business with Europe has improved slightly, so that all the collieries are busy. Prices are firm.

A court of inquiry to investigate the miners' wage question has been named by the Ministry of Labor. Pending the outcome of the inquiry, the present wage basis will be continued. Elimination of the fear of a strike action and the Franco-German extension of the agreement regarding Ruhr coal deliveries are creating an easier tendency in the market and buyers are expecting lower prices.

A cable dispatch to *Coal Age* states that during the week ended April 5 the British collieries produced 5,852,000 tons of coal, according to the official estimates. This compares with an output of 5,745,000 tons during the week ended March 29.

Trade at Hampton Roads More Active; Prices Stiffen

Business at Hampton Roads is more active with considerable foreign movement and a stiffening in prices. Low stocks at tidewater added to the upward price movement.

Coal agencies reported that fully 40 to 50 per cent of the operations on the Chesapeake & Ohio, Virginian and Nor-

folk & Western had closed down temporarily because of overproduction.

Coastwise movement is dull, old contracts having been used up and no disposition being manifest on the part of consumers to come into the market heavily at this time. The tone of the market is firm and the outlook for business bright.

Business in French Market Above Seasonal Level

With the continuance of cool weather, business in household fuel in French markets is more active than usual at this time of the year. Trade in industrial fuel also continues to be satisfactory. With the decline of sterling, there has been a revival of coal buying in England, including a few orders for Cardiff semi-bituminous grades, which had been rather neglected of late owing to their high prices.

Following the meeting in Paris of Belgian and French house-coal producers, the Belgians, who had expected an amelioration of their coal market in the absence of British competition, and who are now fearful of the results of a fall in sterling, have changed their attitude and are now starting to apply summer prices on the following basis: 8 fr. premium per ton on all shipments by water during April, and 8 fr. per ton on all shipments by rail and water in May.

The new tariff of the Nord and Pas-de-Calais collieries, dated April 1, provides for a reduction of 3 fr. in the price of coal, and 8 fr. on ovoids, the new prices being applicable in all selling zones. On sized products, summer premiums are not applicable on ovoids, dry unscreened 50 per cent, nor on bituminous screened 50 per cent, nuts 30/50; dry coal for gas engines washed forging peas or briquets. Prices will be modified in case of wage increases and all taxes, increase on taxes, or any new tax on coal will be charged to the purchaser.

In spite of summer premiums granted by collieries, Paris dealers have decided not to alter their retail market list until further steps are taken.

Receipts of indemnity fuels by France and Luxemburg during March from the Ruhr were close to 1,000,000 tons.

News Items From Field and Trade

ALABAMA

A. B. Aldridge and associates have purchased from the Sloss-Sheffield Steel & Iron Co., 18,000 acres of coal lands in Walker County, 40 miles west of Birmingham, for a consideration said to be between \$300,000 and \$400,000. This acreage is adjacent to land being worked by Mr. Aldridge and associates in supplying coal to the Alabama Power Co. for its big thermo-electric plant on the Warrior River.

The Pratt Consolidated Coal Co. recently completed a small slope at Mineral Springs, near Birmingham, and installed a washing plant for the preparation of the coal.

The No. 2 coal mine of the Alabama Company, at Lewisburg, has reached a depth of around 1,600 ft. and will soon be producing coal in quantity. Contracts have been let for a washery and other modern equipment for the mining and preparation of the coal. It is expected to push the production of this slope to around 2,000 tons daily ultimately, supplementing the production from old No. 1 mine located about a mile distant from the new opening.

The Roden Coal Co. recently installed concentrating tables and dewatering process for the better preparation of its output at Marvel mine, in Bibb County.

Moss & McCormack are doing some prospecting work and making preliminary plans for the development of the large tract of coal lands in Fayette County leased from the federal government some months ago. There is 1,840 acres in this tract, which carries several seams of workable coal, the most valuable and extensive of which is the Jagger seam.

The Gulf States Steel Co. is contemplating the sinking of a new slope and airway at its Virginia coal mines near Bessemer.

The new slope of the Bankhead Coal Co., recently reported, is expected to begin producing coal about June 1. A steel tiple and rotary dumps are being installed and the spur track is about completed. The mine is located at Bankhead, Walker County, the Mary Lee seam being mined.

The Bush interests have recently made additions to their coal-washing plants at Majestic, Bradford and Dixiana, practically doubling the capacity. The output of these mines is used principally in the by-product ovens of the Alabama By-Product Corporation, at Boyles.

ILLINOIS

Herbert E. Bell, of the Bell & Zoller Coal Co., of Chicago, operators of the two big Zeigler mines in southern Illinois, is about to erect a 23-story office building on Michigan Boulevard, in Chicago. R. H. Zoller, vice-president and general manager of the same coal company, a short time ago opened the Lake Shore Drive Hotel, 181 Lake Shore Drive, Chicago, a luxurious eighteen-story hotel fronting on Lake Michigan.

In spite of demoralized conditions in the coal industry, Peabody mine No. 6, near Springfield, made a record hoist one day recently, when it raised 3,717 tons of coal in eight hours, breaking the former record made May 23, 1923, when 3,225 tons was hoisted. A check of figures showed that 1,601 pit cars were hoisted, filling seventy-nine railroad cars.

The Springfield District Coal Co. has purchased about 400 acres of land at from \$75 to \$100 an acre.

KANSAS

Despite the cessation of work in the mines Kansas miners are going ahead with preparations for the state first-aid meet to be held in Arma on May 17. In addition to the state forces C. E. Saxon and P. E. Keegan, of the Bureau of Mines, are conducting a number of training classes.

Alex Howat, who was booted out of the union for calling an unauthorized strike two years ago, must go back to work in the mines in order to get back into the union. This was the word he got from international headquarters of the union at Indianapolis early this month when his case got a sort of hearing. James Harvey, member of the district board in Kansas reported that Howat was informed he was not put out of the union for life but that he must get back by exactly the same route that any other member must follow.

Certificates of completion of 12-week courses conducted under the Smith-Hughes act were presented to more than 150 Kansas miners at their "commencement" in the Kansas State Teachers College of Pittsburg the night of April 9. The men took work in mining, electricity and allied subjects. More than twenty classes were conducted at night in camps throughout the district by instructors of the Teachers College or miners who had been previously trained by the college. Charles F. Spencer, president of the Southwestern Interstate Coal Operators Association, was the principal "commencement" speaker.

The Cherokee Fuel Co. has been purchased by the Sinclair Coal Co., effective May 1. Both are selling agencies with offices in Kansas City, Mo., and Pittsburg, Kan. All the business will be conducted under the Sinclair company. The Cherokee has been handling the output of the Carbon Coal Co. and of the J. R. Crowe Coal & Mining Co.'s Kansas mines. The Crowe company itself sells the output of its Oklahoma mines. E. E. Trotter, Kansas City, sales manager for the Cherokee, will be retained by the Sinclair.

John H. Crawford, presiding judge of the Kansas Court of Industrial Relations, has announced that that body will take no hand in the cessation of coal-mining operations in Kansas. Two weeks after the general stoppage of work found more than 500 cars of coal on the tracks in the Pittsburg field awaiting orders. Under these circumstances no emergency exists, the public welfare is not affected and there is no occasion for the court to intervene, Judge Crawford said.

Attorney General C. B. Griffith of Kansas has given Judge J. H. Crawford of the Industrial Court an opinion that the state mine inspector should pass an examination and be granted a certificate by the State Mining Examining Board before qualifying to hold the position. Leon Besson assumed the position of inspector April 1 without meeting this requirement. Crawford has checked the matter up to the two members of the court, who made the appointment over his protest, and if they do not act it is probable that mandamus proceedings will be instituted by the Attorney-General to compel the inspector to take the examination.

The Central Coal & Coke Co. and the Pittsburg & Midway Coal & Mining Co. have recorded leases on several hundred acres of land in Labette County, near Edna, thirty miles west of the developed Crawford-Cherokee County field. All land within a radius of several miles of Edna is now under lease as well as the entire south portion of Labette County from Edna east of Chetopa. This land is contiguous to large tracts in Oklahoma on which the Central has taken leases within the last two or three years. The Labette County land has been leased for about \$35 an acre with a damage clause calling for \$75 an acre for land used in mining operations. The coal, which is 250 to 425 ft. below the surface, is said to have been shown by drilling to be from 4 ft. to 8 ft. thick and to be shiny black coal of high fuel value. This field is served by the Missouri-Pacific, M. K. & T., and Frisco railroads.

The Valentine Coal Co., capitalization \$60,000, has been granted a Kansas charter. It has holdings near Pleasanton, Kan., and Worland, Mo., where John Valentine, manager and heaviest stock-

holder, has operated shovel mines for some years. The main office will be in Worland. The Kabonic & DeGasperi Coal Co., capitalized at \$6,000, also has been granted a Kansas charter. It is a consolidation of the Kabonic Coal Co. and the DeGasperi Brothers Coal Co., operators of small shaft mines in Crawford County. Its office will be in Frontenac.

The Missouri-Kansas Coal Co., with offices in Kansas City, Mo., has leased for six months, with a purchase option, a shaft mine at McCune, which had been operated for a year by the Osage City Labor Exchange. This is a machine mine and had been handicapped by inadequate electric service, which recently was remedied.

KENTUCKY

E. L. Douglass and John W. Ritchie were appointed receivers for the mining properties of Jewett, Bigelow & Brooks in Kentucky at a hearing before Judge A. M. J. Cochran in the U. S. Court for the Eastern District of Kentucky sitting in Covington on April 15. This action was taken on the demand of several of the creditors not satisfied with the progress being made under the creditors committee appointed late in January. Default on payments to the Harvey Coal Co. of Knoxville, Tenn., former owners of one of the mines of the company also caused action from that quarter. The assets of the company have been estimated at \$5,000,000 by accountants and the financial troubles date back about three years, as told at the time that the creditors committee was formed. Separate action was filed against the Hazard-Jellico Coal Co. because a different set of owners were involved. Mr. Douglass has had direction of the J.B.B. mines for several years and Mr. Ritchie hails from Cincinnati and is the head of the Credit Men's Association there and skilled in the direction of receiverships.

The Deance Coal Co. is soon to build a substation in Happy.

The Chickasaw Coal Co. has been incorporated in Madisonville, with a capital stock of \$25,000, by James D. Overall, J. Basil Ramsey and others.

A voluntary petition in bankruptcy has been filed in federal court by the Drakesboro Coal Co., Drakesboro, Muhlenberg County, listing its liabilities at \$13,197, of which \$13,105 represents unsecured claims and its assets at \$11,080, of which \$10,000 represents property.

MISSOURI

One hundred miners employed by the Madison County Coal Co. have petitioned for a receiver for that company to be appointed by the Circuit Court of Madison County at Edwardsville. The miners in the petition contended that the company was unable to meet a payroll of \$13,000. Thomas R. Harris, of St. Louis, is president of the company. Slow collections are said to have caused the company embarrassment.

NEW YORK

The Mahoning Coal R.R., a subsidiary of the New York Central system, has declared a dividend of 20 per cent on the common stock, payable May 1 to holders of record April 17. A similar dividend was paid on Feb. 1. Patrick E. Crowley has been elected president and a director of the company, to succeed A. H. Smith.

The Atlas Powder Co. announces the removal of its New York Office from the Fifth Avenue Building, 200 Fifth Avenue, to the Park-Lexington Building, Park Avenue and 45th Street, the new phone number being Murray Hill 1411.

John M. Davis, president of Manning, Maxwell & Moore, and George B. St. George, president of the St. George Coal Co., have been elected directors of the **Coal and Iron National Bank**, Liberty and West Streets, New York City. They succeeded John L. Kemmerer, of Whitney & Kemmerer, and Henry Maynard of the Central Railroad of New Jersey, who resigned.

In its annual printed report for 1923 the **Delaware, Lackawanna & Western R.R.** reports net income of \$12,378,001, equivalent to \$7.09 per share on the \$87,277,000 of capital stock of \$50 par value outstanding. In 1922 net income was \$10,475,929. These figures agree with the preliminary report already published.

The **Peerless Anthracite Co.**, of Buffalo, has gone into involuntary bankruptcy. It was established some months ago by H. L. Snyder, of Buffalo, but has not been in

E. J. Berwind, president of the Berwind-White Coal Co., has retired from the directorate of the Erie R.R. active operation lately.

The **Akron Coal Co.**, of Akron, Ohio, announces the opening of a sales office at 872-74-76 Ellicott Square, Buffalo, in charge of J. Fred Morlock.

The **C. P. Brodhead Coal Co., Inc.** will be located May 1 in the Cunard Building, 25 Broadway, New York City.

OHIO

The **Columbus Board of Purchase** has awarded the contract for 10,500 tons of Hocking nut, pea and slack to the **Sunday Creek Coal Co.**, of Columbus, at its bid of \$1.45 at the mines. The freight is \$1.26, making the coal cost \$2.71 delivered. The coal is to be used by the municipal light plant, waterworks department and garbage department.

The **Chauncey mine**, near Athens, is preparing to start operations after an idleness of several months.

The **Northern Fuel Co.**, Columbus, recently chartered, has been organized by the election of H. H. Heiner, formerly president of the Maynard Coal Co., as president, and H. H. Heiner, Jr., vice-president and secretary. Offices have been opened in the Guarantee Title & Trust Building. H. H. Heiner, Jr., will have charge of the Toledo office, which is located in the Nasby Building. The company will wholesale all kinds of coal and has obtained connections with several large operations in West Virginia and Kentucky.

The **Goat Hill Coal Co.**, Bergholz, has been chartered with an authorized capital of 5,000 shares, no par value, designated to mine and buy and sell coal. Incorporators are Harry D. Eynon, John J. Davis, Delmer Johnson, John J. Freed and John C. Amstutz.

The **Boone Coal Sales Company** long established in the Dixie Terminal Building, Cincinnati, have joined the rapidly growing colony in the new Frederick H. Schmidt Building.

The **Norwood School contract** was closed on April 14 with Henry Feldman, of Cincinnati, as the successful bidder. There were eleven firms that put in bids for the business, which called for smokeless coal and the range of prices was from \$4.85-\$6 delivered to the schools.

A meeting of the creditors of the **Maynard Coal Co.**, which has been in the hands of receivers Frank L. Stein and William S. Harman for several months, was held in Columbus April 8, to discuss the possibility of reorganizing the concern. Several plans were proposed for a reorganization so that the receivership could be lifted. A committee of creditors consisting of Messrs. Fox and Meiner of Chicago, bankers, and Fred Essex, a coal operator of Columbus, was named to canvass the situation and report at a meeting to be called later.

Eugene Dubuis, who has been manager of the Columbus office of the Philadelphia & Cleveland Coal Co. for the past two years and previously traffic manager of the same company, has resigned to go with the Consolidated Mining Co., No. 8 East Broad St., in the sales department. H. S. Brown, Cleveland, has been named manager of the Columbus office in his place.

The **Pittsburgh & Bessemer Coal Co.**, of Columbus, has been named exclusive agent in Ohio and northern territory for the product of the Boone County Coal Corporation, of West Virginia. In order to enlarge its sales department D. D. Davidson, formerly connected with the Gibraltar Coal Co., has become associated with the Pittsburgh & Bessemer Coal Co.

PENNSYLVANIA

The Philadelphia & Reading Coal & Iron Co. and the Lehigh Coal & Navigation Co. have awarded contracts for anthracite stripping operations near Pottsville, in the Mammoth vein, said to be one of the largest in the world, reaching a thickness of 100 ft. in some places. The Philadelphia & Reading will open thirteen mines on Locust Mountain from Ashland to Shamokin, the Lehigh contract being for operations on land controlled by one of the company's subsidiaries. It is expected that more than 4,000,000 cu. yd. of earth and stone will be removed in the latter operation and that about six years will be required for its completion. An electric shovel weighing 38 tons will be used.

Effective April 1st, the **Pittsburgh Steel Co.** began operating its coal and coke operations under the name of the **Monessen Coal & Coke Co.**, instead of the **Pittsburgh Steel Co.**, as heretofore. The company's operations are Alicia No. 1, near Brownsville, in Fayette County, consisting of a large shaft mine, 400 rectangular coke ovens, coke screening and storage plants, with both river and rail loading facilities, machine shop and marine way, and Alicia No. 2, in Greene County about twenty miles up the Monongahela River from Brownsville, consisting of a large coal mine with both river and rail loading facilities.

The property of the **LaBelle Coke Co.**, at LaBelle, Fayette County, on the Monongahela River and the Monongahela Ry., which has been held under lease by the Peabody interests of Pittsburgh, is being taken back by the owners, the LaBelle Iron & Steel Co. The plant, consisting of 200 beehive ovens and a mine, has been idle since the middle of last month, due to refusal of the employees to work for reduced wages. The employees have not been paid since the mine ceased operations, and on April 1, the company store and office were completely destroyed by fire, thought to have been of incendiary origin. The LaBelle Iron & Steel Co. is a subsidiary of the Wheeling Steel & Iron Corporation.

A state charter has been issued to the **Daugherty Mining Co.**, to acquire coal lands and develop and operate them, with a capital stock of \$15,000. The incorporators are Percy M. Willis, Hendersonville, treasurer; Henry C. Daugherty, Finleyville, and Jesse C. Bortz, Hendersonville.

In order that the company can perform two operations at one stop, the **Baltimore & Ohio R.R.** has purchased 23 acres of land at the Yoder coaling station, at Myersdale, on which the company will construct a twenty-three acre storage dam for water for engines and erect a watering station in connection with the coaling station. The dam will impound a large body of unpolluted water, suitable for steaming purposes.

The **Jeddo-Highland Coal Co.**, will begin work soon on a new stripping operation in the Lehigh region. A mining village now occupies the site that will be worked.

Elmer O. Long, formerly of the engineering department of the Consolidation Coal Co., has resigned to accept the position of superintendent with the Listie Que-mahoning Coal Co., having charge of four mines in Somerset County.

UTAH

Utah loses all title to school section land in Kane County, township 40 south, range 8 west, by a decision just handed down by Eli F. Taylor, U. S. register of the land office. The Government contested the title on the ground the land was known to contain coal before the state's title attached. Section 2 in township 41 south, range 9 west, is retained by the government in the same action. Kane County is well provided with coal lands though they have never been developed as they have in Carbon County.

The cost of state inspections of coal mines in Utah, according to the Utah Industrial Commission, was less per million tons of coal mined in 1923 than in Wyoming, Colorado or Washington, being but \$550 for every million tons of coal mined during the year.

The **Great Western Coal Co.**, which filed leases on coal lands in Gordon Creek, Carbon County, was the successful bidder at the auction for the leases last week. A minimum of 27,000 tons annually must be mined by the company and \$45,000 must be expended on development in three years.

WEST VIRGINIA

The **Wheeling Steel Corporation**, Wheeling, is planning one of the largest coke-manufacturing plants in its section of the United States. The company's present plant across the river from Steubenville, Ohio, is to be increased. Ground has been broken and several hundred men are at work on this project. More ovens will be built and the present construction of the plant will be changed, as the plant is now working at capacity, but is unable to feed all of the corporation's furnaces. The company also will have one of the largest industrial railroad yards in the Ohio Valley to handle cars used for raw and finished products.

The **Sterling Island Creek Coal Co.** is the name of a new concern organized with a capital of \$25,000 to produce coal in the Logan County field. Among those interested in this company are W. L. Taylor, of Logan; W. T. Spicer, Molly Spicer, B. T. Spicer and Eddie Cameron, of Stollings. The company's general office is to be at Stollings.

G. H. Nowlin, Jr., of Lynchburg, has resigned as president and treasurer of the Smith Pocahontas Coal Co., effective April 1. The Smith Pocahontas Coal Co. operates mines at Caloric, W. Va., the general offices of the company being at Lynchburg.

The **Cleveland-Morgantown Coal Co.** has purchased 115½ acres of Sewickley coal in the Cass district of Monongalia County from Allison S. Everly and wife. The consideration was \$46,316. Henry A. Phillips has purchased 64½ acres of Pittsburgh coal in Clay district of the same county, the consideration being \$11,448.

Robert Talbott, well known in Fairmont coal circles, and his associates have just organized two new coal companies. One of them is to be known as the Talbott Fuel Co. and is capitalized at \$450,000. Interested in it are Robert Talbott, J. Paul Talbott, Robert Talbott, Jr., H. Glenn Hood and C. A. Hannah, all of Fairmont. The other new Talbott concern is to be known as the Robert Talbott Co., also with offices at Fairmont. This company is capitalized at \$350,000, the same people being incorporators.

James E. Barnes has resigned as second vice-president and district sales manager of the Logan Fuel Co. He had been in charge of the Dayton office of the company. Mr. Barnes had been active in the coal industry for the last 20 years. It is stated that Mr. Barnes will devote the greater part of his time in the future to the Dayton Standard Scale Co., of which he is general manager.

The **Harlan Ashless Coal Co.**, of North Fork, has just been launched with a capital stock of \$150,000, the general office to be at North Fork. This company was organized to operate in McDowell County on an extensive scale. Largely interested in the new company are Abe Forman, of Kimball; Harry Totz and W. S. Ray, of North Fork; M. H. Clark and P. G. Haines, of Welch.

WASHINGTON, D. C.

The appeal of James C. Davis, Director General of Railroads, against **Dexter & Carpenter, Inc.**, was sent April 14 by the U. S. Supreme Court to the **Circuit Court of Appeals for decision**. This involves a suit by Dexter & Carpenter for additional compensation for coal seized in the name of the Director General just prior to the coal strike of 1919 and used in the operation of the Baltimore & Ohio R.R. The coal from West Virginia mines, was en route to Baltimore for export when seized. The Director General paid the company the mine cost of the coal. The company sued for additional reasonable compensation. The District Court decided against the company, but the Circuit Court of Appeals reversed this and the District Court then awarded \$27,264. It was from this that an appeal to the Supreme Court was taken. The high court decided that the Circuit Court of Appeals should pass upon the award.

CANADA

The **Eastern Coal Dock Co., Ltd.**, of Montreal, with a capital of \$50,000, has been incorporated to manage dock properties and carry on business as coal dealers by Edward W. Wright, John B. Allen and D. J. Nickle, all of Toronto.

Traffic News

To Reopen New England Rate Division Case

Announcement was made in New York on April 14 that the Interstate Commerce Commission will on May 12 reopen the New England rate division case.

The roads that will lead the fight for a modification of the terms of this decision are the Central Railroad of New Jersey and the Delaware & Hudson, but it is expected that numerous other lines also will appear before the commission. The Erie filed an application for exemption before either of these roads, and it is understood that the roads of the Central freight territory, such as the Wabash and the Pere Marquette, contemplate entering the fray.

Meanwhile, according to counsel for one of the roads concerned, the New England roads have opened negotiations looking toward a settlement of the case, which was in the courts for more than a year previous to the final decision by the Supreme Court upholding its validity last summer, without further litigation. While they have not indicated just what measures they will take to counteract the effects of the move by the Jersey Central and the Delaware & Hudson, it is believed that these lines will bring forward proposals of their own for increased divisions even over the present rates.

The New England lines affected include the New York, New Haven & Hartford, the Central New England, the Boston & Maine, the Central Vermont, the Rutland, the Maine Central, and the Bangor & Aroostook. The last-named road did not participate in the benefits conferred by the decision on the rest of the New England group.

The "New England divisions" situation grew out of a decision handed down by the Interstate Commerce Commission in 1922 awarding these roads approximately 15 per cent higher returns than they had previously obtained on through freight traffic. The decision was sustained in the Supreme Court last August, but at that time the court indicated that, although the decision was just in its general application to the situation, individual roads should be permitted to seek relief from its provisions.

New Rate War in Northwest

A freight-rate war is in sight on coal from western Kentucky to the Northwest, having been started by a low rate instituted by the L. & N. to points on the M. & St. L. in Minnesota and South Dakota, which are 80c. to \$1 lower than rates on other lines. A similar reduction is promised to points on the Chicago Great Western which would affect southeastern Minnesota and Iowa points. It is asserted that if these reported low rates are continued it will cut off Illinois and Indiana mines from the business of the Northwest. There is general displeasure being voiced by many coal interests and railroads.

Oppose Building of 50-Mile Coal Line by M. K. & T.

Examiners of the Interstate Commerce Commission oppose the building of a 50-mile branch line into the Henryetta (Okla.) coal fields by the Missouri, Kansas & Texas R.R. The company uses oil-burning engines and asserts that it might be forced back into coal burners at any time and would need its own coal supply. The examiners say there is an adequate coal supply for the railroad and to open a new coal field would cause overproduction.

Mine-Rating Case Hearing May 19

Hearings in the mine-rating case, postponed from April 23, will be held by the Interstate Commerce Commission May 19. Commissioner Aitchison will preside.

Coming Meetings

Chamber of Commerce of the United States. Twelfth annual meeting at Cleveland, Ohio, May 6-8. Secretary, D. A. Skinner, Mills Bldg., Washington, D. C.

Illinois Mining Institute. Annual meeting, June 12-14 from St. Louis via boat down the river. Secretary, Martin Bolt, Springfield, Ill.

National Exposition of Coal Mining Equipment and Machinery of the American Mining Congress, May 12-17, Cincinnati, in conjunction with the annual meeting of the National Coal Association.

West Virginia Coal Association. Annual meeting May 13-17, Cincinnati, Ohio. Secretary, W. H. Cunningham, First National Bank Building, Huntington, W. Va.

National Coal Association. Annual meeting, May 14-16, Cincinnati, Ohio. Executive Secretary, H. L. Gandy, Southern Building, Washington, D. C.

Mine Inspectors Institute of America. Annual meeting, Sinton Hotel, Cincinnati, Ohio, May 14-16. Secretary, Martin Bolt, State House, Springfield.

Retail Coal Dealers Association of Texas. Nineteenth annual convention, May 20 and 21, Vernon, Texas. Secretary, C. R. Goldman, Dallas, Texas.

Pennsylvania Retail Coal Merchants Association. Twentieth annual meeting and exposition, Commercial Museum, 34th and Spruce Sts., Philadelphia, Pa., May 22-23. Secretary, W. M. Bertolet, Reading, Pa.

International Railway Fuel Association. Sixteenth annual convention, May 26-29, Chicago, Ill. Secretary-Treasurer, J. B. Hutchinson, 600 Michigan Ave., Chicago, Ill.

The American Society of Mechanical Engineers. Spring meeting May 26-29, Cleveland, Ohio. Secretary, Calvin W. Rice, 29 West 39th St., New York City.

American Wholesale Coal Association. Annual convention, White Sulphur Springs, W. Va., June 3-4. Secretary, G. H. Merryweather, Chicago Temple Bldg., Chicago, Ill.

The National Foreign Trade Convention. June 4-6, Boston, Mass. Secretary, O. K. Davis, 1 Hanover Square, New York City.

National Retail Coal Merchants' Association. Annual meeting, Hotel Virginian, Bluefield, W. Va., June 4-6. Secretary, Walter D. Rogers, Transportation Building, Washington, D. C.

Southwestern Interstate Coal Operators Association. Annual meeting June 10, Kansas City, Mo. General Commissioner, W. L. A. Johnson, Keith & Perry Bldg., Kansas City, Mo.

Illinois & Wisconsin Retail Coal Dealers Association. Annual meeting, June 10-12, Delavan, Wis. Secretary, I. L. Runyan, Great Northern Bldg., Chicago, Ill.

American Society for Testing Materials. Annual meeting, Chalfonte Hotel, Atlantic City, N. J., June 23-27. Secretary, Edgar Marburg, University of Pennsylvania, Philadelphia, Pa.

New Equipment

Rubber-Jacketed Portable Electric Cable

A heavy-duty portable cord with unusual tensile strength has been developed by the United States Rubber Co., 1790 Broadway, New York, for use under severe conditions. This cable is especially suitable for electric light extensions, and for use with portable electric tools. Much of this kind of cable is now in use on cable-reel locomotives, and in electric storage battery charging stations. When the cable is made up of two conductors, polarity identification is made possible by the use of different colored compounds used upon the individual wires. The two conductors are twisted together and the interstice filled with cotton to make the complete cable round. The outer jacket is of special rubber compound for resisting wear and the deleterious effects of acids and oils.

Hook Stick Makes Fusing Safe

A convenient and safe means of opening and closing the circuit of insulator and expulsion type cutouts, also for renewing fuses or for performing other operations is afforded by a combination safety plug puller and switch hook recently designed by the General Electric Co.

The device consists of a fitting

Fig 1—Safely Removing Fuse Plug

The fitting on the end of the pole securely grips the plug, and a slight pull easily withdraws it. There is no need to touch any part of the cutout until it is safely removed from contact with the line wires.

Fig. 2—Opening Fuse Compartment By Hook Stick

The use of the pole makes the opening of a fuse box of this type safe, the fitting on the end of the pole being specially adapted for this service.

mounted on the end of a treated maple pole. The enlarged portion of a slot in the fitting is slipped over the knob of the cutout plug, it is then guided to a position at the end of the slot where it is securely held by means of a spring. The puller is readily removed from the plug by a slight upward pressure and side push. The use of the puller makes it unnecessary to touch the plug with the hands at any time during its removal or replacement in the cutout.

A standard switch hook, mounted at the other end of the pole is designed to operate such expulsion type cutouts as are equipped with ring handles for this purpose. The device is suitable for use on circuits of 7,500 volts or less.

Meters Little Larger Than Their Scales

To meet the growing need for instruments which require minimum switchboard space and which nevertheless are accurate and easily readable, the Weston Electrical Instrument Co. of Newark, N. J., has recently developed a complete line of instruments of rectangular shape. All the meters of this group have uniform cases $5\frac{1}{2}$ in. wide.

New Rectangular-Shaped Switchboard Instruments

Left—Wattmeter, and ammeter with cover removed.

Center—New instrument superimposed over round pattern showing scale openings and how same scale length was preserved.

Right—Triplex ammeter.

The scale on the new meters is the same size as in the instruments with round cases yet the switchboard space requirement of four instruments mounted side by side is about three-quarters that required for the round instruments. The illustration shows how this economy of space has been accomplished.

Where separate ammeters are required, as on three-phase circuits the triplex instrument, shown in the illustration, is useful. Larger and heavier scale numerals together with increased scale openings have greatly increased their legibility.

The wiring studs in the rear of the instruments have been grouped in the center. Resistors, whenever used, are much smaller than usual and are mounted on studs projecting from the rear.

Expansion Tank for Large Capacity Transformers

All transformers larger than 200 kva. made by the Pittsburgh Transformer Co. are air-tight and can be equipped with the new improved expansion tank recently designed by the company.

The tank minimizes the entrance of dirt and dust into the transformer oil; prevents rusting of the inside of the transformer tank; eliminates explosions due to ignition of any gas in the transformer; minimizes chance of moisture getting into the main tank, because a sump is provided in the expansion tank to drain off moisture; gives longer life to the insulating materials; and protects the oil from oxidation, thus tending to prevent sludging. The transformer tank can be completely filled with oil, thereby increasing the radiating surface due to the contact of the oil with the cover. Thus excessive heating and sludging of the oil is materially reduced.

Auxiliary Tank Keeps Transformer Oil in Good Condition

The pipe connection between the transformer tank and expansion chamber extends above the bottom of the latter, thus preventing moisture passing into the transformer. A pet cock at the bottom of the expansion tank drains off any water which gets into the oil.

Industrial Notes

In connection with numerous other improvements being made at the plant of the **Covel Smokeless Coal Co.**, at Covel, W. Va., a shaker screen is being installed by the **Roberts & Schaefer Co.**, of Chicago. The general office of this company is at Tams, W. Va.

The Cincinnati branch office of the **Stephens-Adamson Mfg. Co.** will, in the future, be in charge of **Walter E. Harris**, who for years has been the district manager at the **Huntington (W. Va.)** office, and is therefore widely known in the trade as an engineer and salesman of conveying and coal-tipple machinery. Mr. Harris will continue to head the **Huntington sales**. The engineering staffs of the company at both offices will be enlarged.

Willis C. Lincoln has been appointed Western sales manager of the **Electric Service Supplies Co.** with headquarters in that company's Chicago office. Mr. Lincoln has resigned from his former connection as manager of sales and engineering for the **National Railway Appliance Co.**, New York.

The **Simplex Wire & Cable Co.**, Boston, Mass., is enlarging its facilities for the manufacture of paper-insulated cable, a new four-story building with 40,000 sq. ft. of floor space having been constructed for the purpose. Increased storage space and larger laboratory facilities also are to be provided. The company's "Tirex" portable cord plant likewise is to have added facilities by the addition of 30,000 sq. ft.

The manufacturers of **Strom ball bearings** have changed the name of the company from the **U. S. Ball Bearing Mfg. Co.** to the **Strom Ball Bearing Mfg. Co.** No changes have been made in the personnel of the company, which is located at 4527-67 Palmer St., Chicago, Ill.

Lack of snow and rain in the **Sierra Nevada Mountains** threatens to reduce substantially the hydro-electric output of California, with consequent effect on economic conditions. Steam plants which are being rushed into service are said to be unable to meet the demand.

NEW YORK, MAY 1, 1924

Number 18

"Safety at Last"

"SAFETY FIRST" has been bandied about for years without much result, at least at coal mines. "Safety at Last" might be a better description of our hope. Surely we have made little enough progress in the last decade or so. Now the Phelps Dodge Corporation with steeds thrice stolen is endeavoring to see if there is not somewhere a lock that will secure the stable door. With water, steam, adobe and rockdust, with shelving, gunite and projected dust, with sprayed undercutters and cars not loaded above the sides, surely the projected "Safety at Last" will be attained and none too soon.

It is fair to say that in no industry, save a few smaller ones like powder manufacture, is safety less readily attainable. The road to safety in coal mining is long and devious, we cannot start on our way too soon. Even as we write the Benwood mine disaster assures us that the journey to "Safety at Last" is almost as long as ever, though legislation in favor of rock dusting may be like an automobile lift on the weary road.

How Not to Avoid Taxes

OPERATORS having idle lands are disposed to operate them so as to make them earn something with which to pay their taxes. In many instances that is an ill considered action. The taxes have to be paid in any event. Why not let one area pay the taxes on another? The area worked can be made more efficient, forces will not be divided, and in the end, larger profits will be made. If a mine is opened in another county or township the taxes in that political subdivision will be increased with advancing prosperity and as a result, the total taxes paid in the long run may be higher rather than lower.

Unfortunately one's nature rebels against paying taxes indefinitely on an undeveloped, non-earning property, and the decision is made to develop it so as to make it pay its way—and perhaps something more. But this is a tendency to be resisted till the first territory is being operated at maximum efficiency and at such speed as to assure that the coal will be exhausted within the economic life of the surface buildings.

Twenty years from now better mining methods will have been discovered, and the mines opened now to meet the taxes will not be suited to the methods of that day. The only advantage of a new mine is a shorter haulage underground. The new mine will require less equipment than the old one, but just as much additional equipment in the old mine will provide the development that the new mine would supply.

A new mine absorbs all the enthusiasm that should fall to the old one, and the old operation becomes

neglected. It is best to curb that psychological desire to open up acreages just because they are a steady drain on income, for they may drain still more heavily when opened. Unfortunately, managers often are required to do not what is right but what is urged on them by impatient directors, who argue "Why did we buy if not to use what we bought?"

Union and Non-Union Territory

WITH few exceptions, union mines are in sections of the country having diversified industries, non-union mines being in areas where the coal and perhaps the lumber industries are the sole commercial activities. Difference of opinion will be expressed as to why this is so. Some will say that unionism cannot flourish where there are no other industries to which union men can escape when a strike comes and that where coal is the only industry the stores are not sufficiently financed or are owned by the coal companies. In the one case the merchant cannot support the idle union men and in the other case he will not. In that event the union men, who cannot get work during a suspension, cannot get supplies either and strikes fail.

Others will say that the age of the coal territory determines the degree of organized action of the employees and others again that coal-producing territory which has had many years of life develops capitalists who can invest in other industries and so has these activities as well as coal mining. Eventually they add, all territories which produce coal will be union and will produce other merchandise than coal.

Cause and effect are often difficult to separate and so much depends on leadership and solidarity among operators and mine workers that the social forces do not follow any law blindly. Wyoming, for instance, as far as the coal-mining regions are concerned, is a one-industry state, though cattle raising and sheep farming dispute this generalization. It is, however, neither old nor non-union. Maryland is old and has some local industries, yet it is largely non-union though it has many union adherents. Alabama has varied industries but is non-union.

With such exceptions in mind, however, it is nevertheless possible to state broadly that union areas have diversified industries, with farming as one of the more important of them, whereas non-union areas produce nothing but coal. In consequence, in times of a poor coal market men in non-union fields are not stimulated to discontent by higher wages or steadier work in industries competing for their labor. In fact if they left the mines their wages would be immensely lowered and work would be hard to obtain, whereas near union mines if wages were lowered it would be possible to get other work; and hence wages, regardless of the union, would have to be relatively higher than those in undeveloped or purely coal regions.

It is for this reason, or should it be these reasons, the non-union mines can lower wages to a figure to which the union mines could not lower them were there no union with which they had to deal. The non-union areas have naturally a low wage scale and can have it without any great discontent. The union areas have inevitably a high wage scale and must maintain some such scale or lose their men. This has proved to be a fact time and time again. The non-union fields have repeatedly lowered wages to a level to which the union fields could not have lowered them even if the union had not existed.

Miners are fairly mobile, but most of them merely move from one camp to another nearby. They rarely change from field to field. They are more mobile than in Europe, especially foreigners, but they do not leave one field for another readily. The cost and the uncertainties involved in moving make them "flit" rather than "fly," "move" rather than "migrate." Consequently wages will continue to be determined by local competition for labor rather than by national or international competition except where a strong union interposes to compel something resembling a uniformity of remuneration per unit of effort.

Too Many Grocery Stores

FOR many years the public has been cognizant of the fact that there were too many small retailers, men who made but little profit and used the labor of too many men, who scurried around for a little business that a few men could have handled had there been fewer establishments in the business.

That condition is duplicated at our bituminous mines. We should have fewer and better mining plants. The staffs at a number of mines should be concentrated on but half the number and every effort should be made to make these effective units instead of the limp organizations they too often are. The equipment in each mine should be the last word in effectiveness and efficiency, and no company can afford to make a general rejuvenation of all its properties at one time.

The wagon mine is not the only operation being eliminated; there should be many more mines than these laid idle, many of them of larger capacity, some of them perhaps efficient enough in their way as standards in the past have run, but not needed by the corporation that is operating them.

There are two reasons for closing down excess mines. One is that a mine working only a few days in the month does not produce cheap coal. One working only eleven days, for instance, finds its production cost raised almost 25 per cent. Working only seven and a half days, the cost of production is raised about 50 per cent. Another reason is that, as most companies can afford to equip well only a few mines with mechanical loaders and conveyors and all the proper equipment for safe, efficient and up-to-date operation such as will give reductions of almost 50 per cent in operating cost, it is better to close down a few mines and transform the rest. The latter will amply take care of the larger tonnage which low-cost production will afford, for reconstructed they will produce as much as the many mines now or formerly being operated.

We cannot afford to have mines working as listlessly and inefficiently as grocery stores.

Getting Down to Real Business

AT LAST there appears to be some hope that the manufacturers supplying the mining industry will adopt a one-price policy. Retail buying, especially of staples, has long been standardized, but when it comes to contracts for large quantities or big units, price-trading and bargaining is the indoor sport of the day.

In some sections of the field the practice of bargaining and price-cutting has become so bad that it is markedly uneconomic and unfair. Frequently the manufacturer submits his bid at a price much higher than that at which he expects to make a sale, and most of his agents' time is spent trying to find out, by any means possible, how much the original price must be shaded to get the contract. It is not unusual for many manufacturers' representatives to hang up at an expensive hotel for a week or more waiting an opportunity to get the inside track on the price. It is easy to see how an overzealous sales representative may reduce his price, on a wild tip, to a point where the manufacturer must sell at a loss.

The purchaser often sacrifices most when he thinks he has gained most. Brow-beating and delay sometimes make it possible for the purchasing agent to place an order at a price perhaps a thousand dollars or more under the first figures. But how does this react when the manufacturer realizes he can make no profit at the figure accepted? Does he not lower the quality of his product, let a defective part go into the order, refrain from sending along with the equipment the construction engineer who he intended should aid in its installation, omit important accessories which he would ordinarily supply?

How easy it is for the manufacturer and particularly a jobber to make up his loss on the sale of the original equipment by putting a high price on the repair parts, which generally do not receive the personal attention of the purchasing agent.

Then too, the purchaser must consider the demoralizing effect upon the engineering personnel when they find that they have recommended the purchase of one company's product and received that of another because the purchasing agent has been able to get a better price from another bidder. The losses occasioned by such last-minute changes after the engineering department has designed a layout and bought most of the material to fit in with the equipment recommended, are rarely less than the savings in first cost effected by the purchasing department.

Both manufacturers and coal companies will have to display considerable courage to minimize such economic crimes. The salesman's attitude must be changed and the purchasing agent will have to be made to feel he can serve best when he can confidently place his orders for good materials at a reasonable profit to the seller.

THE PRESIDENT OF A COMPANY is the court of last resort, the man who decides the big issues. Seldom are these men competent to make such decisions. Quite often they are lawyers, physicians, coal jobbers, traffic men—anything but engineers. Thus they need an exposition to clarify their ideas, and they will go to Cincinnati. But some are engineers themselves, you will say. But why speak of them? They will be there of volition as much as from a sense of duty.

Minimizing and Localizing Coal-Mine Explosions

Haulage Roads Adobe Dusted, Manways Rock Dusted
—Dust Barriers Placed at Strategic Points—Air Heated
by Radiators and Humidified by Steam and Water
—Undercutter Chains and Loaded Cars Sprayed

BY W. C. HOLMAN

Chief Engineer, Stag Cañon Branch, Phelps-Dodge Corporation
Dawson, N. Mex.

THE many coal mine disasters occurring during the past year have given impetus to, and aroused increased activity in, the study of ways and means for the promotion of mine safety. In the West particular interest has centered in the methods available of minimizing and localizing gas and dust explosions. At the present time much attention is focused on the experimental work being conducted at the Dawson coal properties of the Phelps-Dodge Corporation.

Through the co-operation of the management, the foremen and individual employees, much already has been accomplished. Officials of this company are always on the alert for new methods, continually conducting experiments, improving existing practice and rigidly enforcing safety rules, all of which tend to improve working conditions and to stimulate interest in safety.

In order to lessen the possibility of an explosion, as well as to dampen or arrest its propagation should it once start, "adobe" dust has been spread several inches deep on the main haulage roads throughout all mines. In each operation the main haulage is the intake air-course, and the disturbance caused by moving trips is sufficient to stir up this dust, whereupon the ventilating current carries it appreciable distances, depositing it upon ribs, roof, timbers and the like. Such inert dust deposits would undoubtedly tend to prevent the propagation of an explosion, no matter in what part of the mine it might initiate.

Fig. 1—General View of Surface

Openings to mines Nos. 1, 3 and 6 may be seen in this picture, also blacksmith shop, motor barn, fan house, mule stable, check cabin, lamp house and other structures.

Samples of dust from floors, ribs, roof and timbers are taken regularly each month and analyzed by the local chemist. A combined sample taken from all the mines ordinarily will show 85 per cent of incombustible matter or ash.

All motor roads that are treated with this adobe dust are continually raked and cleaned, one man in each mine being employed for that express purpose. He separates the coal and rock from the dust, piling them along the entry. These piles are removed about every two weeks. The dust itself is renewed from time to time as may be required, the length of these intervals depending much upon the ash content as shown by the report of the chemist. Loaders are not allowed to heap coal to any appreciable height above the sides of the mine cars. This is done primarily to prevent the scattering of broken coal along the haulage roads and also to avoid waste.

USE ROCK DUST WITH CEMENT GUN

Experiments are now being conducted in the manways of the various mines on the use of rock dust as a preventive of the spread of explosions. Quartzite or other metamorphic rock is crushed to pass a 200-mesh sieve, then thoroughly dried and sprayed into the air-course by means of a cement gun. By this method the floors, ribs and roofs of the entries are coated with this inert material. Rock dusting appears to be more economical than adobe dusting in return air courses and in such intake courses as are not used as main motor roads.

The use of adobe and rock dust on intake aircourses in all mines is now considered standard practice by this company. Beyond doubt it forms an effective safety measure for minimizing and localizing possible explosions. A scheme for coating the ribs and roof of all motor roads with adobe mud is also being tried. This is sprayed into place by means of a cement gun. The gun is mounted on a special truck, to which is attached a compressor and water tank as well as cars containing the adobe and all necessary accessories. The entire train thus formed is drawn through the mine by an independent electric locomotive.

In order to reduce the possibility of an explosion still further batteries of V-shaped troughs forming dust barriers have been installed at strategic points on the main entries and air courses and at all intersections of cross entries with main entries both on the haulage roads and return aircourses. A battery con-

sists of sixteen V-shaped troughs each from 10 to 20 ft. in length depending upon the width of the entry in which they are installed. These troughs are made from 1x8 in. boards and are supported near the roof of the entry on 2x6 in. stringers. They are filled with dry shale or rock dust which will average about 95 per cent ash. This dust is periodically tested and is renewed whenever it becomes too damp or too greatly contaminated.

At present the number of dust batteries installed in the various mines is as recorded in Table I.

Table I—Batteries in Phelps-Dodge Corporation Coal Mines

Mine. No.	Batteries	Mine. No.	Batteries
1	17	6	32
2	21	8	17
3	27	9	20
5	12		

Five automatic water barriers have also been installed on the main haulage road of Mine No. 5. Each of these consists of four ¾-in. automatic water sprays discharging within a space of about 10 ft.

As an experiment in humidification of the mine atmosphere, live steam is conducted into the main motor road of Mine No. 5 for a distance of 700 ft. Here it is forced through radiator coils from which it is discharged by ¾-in. steam jets into the air current. A 200-hp. boiler, installed near the mine portal, generates steam at a pressure of about 13 lb. gage. From the boiler it is conducted into the mine through a 3-in. main to eighteen of these radiators, each of which is made up of 1½-in. pipe in the form of an L, 10 ft. on the long side and 5 ft. on the short side, with a 2-in. junction pipe on each end. Each radiator is fitted with two ¾-in. steam jets which, together with five ½-in. jets on the main line, discharge steam into the air current.

In connection with this humidifier a ¾-in. automatic spray has been installed about 300 ft. beyond the radiator. This raises the humidity of the air slightly more than 10 per cent at this point.

Tests conducted throughout the mine showed a minimum humidity of 95 per cent at a temperature of 60 deg. F. during the month of January, 1924. The humidification system installed in this mine is in addition to

the trip sprays later described and the dust barriers already mentioned.

The cement gun is being used to cover the ribs, roof and timbers on the main motor road in all mines with a thick coating of gunite mixed in the proportion of one part cement to four parts of sand. When gunited all cracks and crevices are filled and the ribs present a far smoother surface than before, thus reducing the friction offered to the air current. No ledges or shelves protrude upon which inflammable dust may accumulate. Furthermore, the entries are lighter and more sanitary than before.

In all main entries 3-in. pipe is carried to within a few hundred feet of the advancing face. In tunnel entries 1½-in. pipe is used up to within 50 ft. of the face. These lines are provided with suitable connections every 100 ft. to permit of a hose being attached for sprinkling purposes.

In all rooms ¾-in. pipe is laid to within 20 ft. of the face, and 20 ft. of rubber hose is furnished to enable the miner or loader to sprinkle the coal before loading it into mine cars. The loader not only sprinkles the loose coal but is required to wet down the surrounding ribs and gob thoroughly for a distance of 50 ft. from the face. Regular sprinklers are employed to keep all mule-haulage roads and secondary aircourses in a safe condition.

To each mining machine a ¾-in. pipe is attached. This is reduced at the end and bent downward so as to allow water to flow on the feed side of the cutter chain, this pipe being connected to the water line by a 50-ft. hose. Thus while the machine is in operation water is discharged under the cut, saturating the coal dust as rapidly as it is made. The use of this device allays all coal dust produced in the undermining of the coal.

MINE CARS ARE DRENCHED WITH SPRAYS

Moreover, all loaded car trips are drenched by sprays before leaving their respective districts, and this process is repeated on the main partings. These sprays are made from 1½-in. pipe bent to form a loop about 36 in. in diameter and perforated with ¼-in. holes. Water is sprayed from them in such volume that each car receives about 15 lb. in passing. Water for operat-

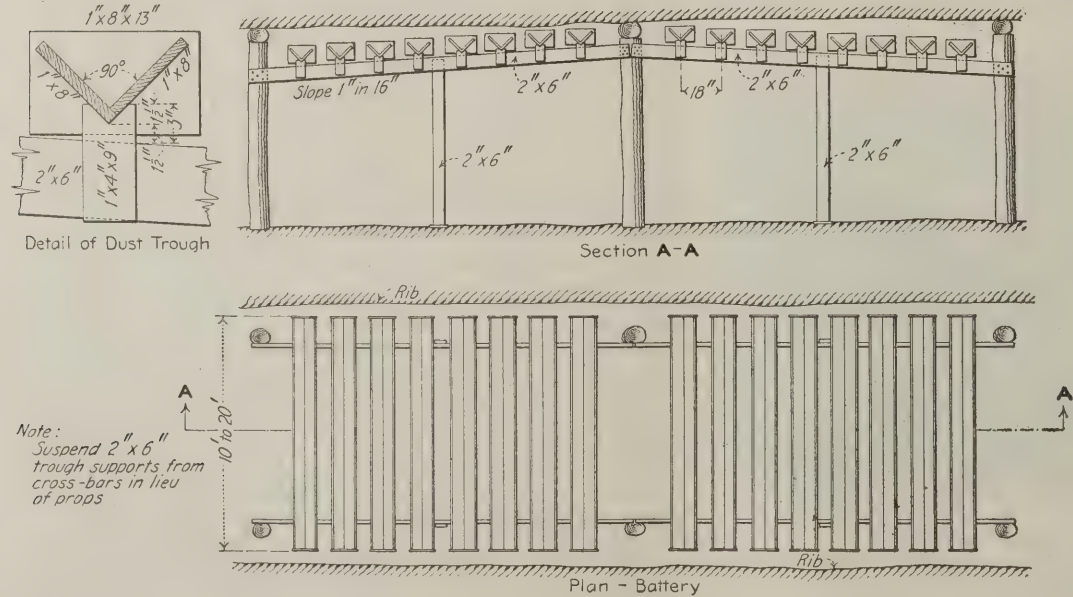

FIG. 2
A Dust Barrier
Fine stone dust is placed in the troughs which are supported near the roof of the heading in such a way that the force of an explosion even though comparatively incipient will upset them. The dust will therefore fall in a series of sheets extending across the heading effectively damping and extinguishing the explosion flame.

Fig. 3—The So-Called Silent Foreman

Of repeated reminders of possible danger do much to render men careful. They are most effective when given by word of mouth, but the next best thing is to make them visual. Posters, each carrying a warning of danger or admonition to be careful are here shown pasted to the sides of locomotive and mine cars.

ing the sprays and for sprinkling is pumped from the mine workings either directly to the main or into elevated tanks placed at such points on the surface as to secure a gravity head. The height at which these tanks are installed is determined by the pressure necessary. They are always kept full so that they may furnish water for sprinkling requirements in case of trouble with the pumps. Connections are also maintained with the city water mains.

The number of trip sprays maintained in the mines at the present time is recorded in Table II.

In these mines the electric arcs caused by the usual type of trolley locomotives are regarded as a possible source of danger. Consequently storage-battery locomotives are now being installed experimentally. This installation will comprise 15-ton storage-battery machines so designed that they may be operated either singly or in tandem. The standard battery unit will be of 80 cells mounted on a four-wheel truck. When operated in tandem two of these units will constitute a single locomotive. This will be 16 ft. 6 in. long, 57 in. high and 68 in. wide, these being approximately the dimensions of the heavy locomotives now being used for main haulage. The charge in each unit will be freshened every time the machine reaches the outside which on an average will be once an hour. During the night the locomotive batteries will be completely charged.

Mining machines likewise will be equipped with 29-plate, 88-cell batteries carried on trucks especially designed to meet the requirements of the underground workings. By these means the ordinary electric sparks and arcs caused by the trolleys will be entirely eliminated.

At all mines double-inlet reversible fans are employed for ventilation purposes. These normally operate exhausting. Mine No. 5 is fitted also with an auxiliary fan. All these mine fans are operated on 220-volt current except those at Mines Nos. 1, 2 and 5, which are run on 2,200-volt circuits. In every instance a separate line supplies power to the fan.

The various mine offices, motor barns, lamp houses,

etc., are connected to the fan houses by an alarm system. This is intended to give warning in case of trouble with the fan motors. The largest fans in operation are those located at Mines Nos. 2 and 3. These are 18x6ft. machines rated to deliver 400,000 cu.ft. of air per minute against a 5-in. water gage, when operated at 150 r.p.m. Each normally consumes about 420 hp. Periodic tests are made of the power consumption and air delivery of these fans. When necessary, changes are made in their operation to assure that the required quantity of air is supplied to the mines.

One highly important detail of the ventilating system is the provision that air passing through worked-out or gobbed areas is not allowed to circulate through working places but is returned direct to the main aircourse. It is the practice to wall off as rapidly as possible all caved and abandoned workings. Concrete or cement blocks made of coke breeze are used for all permanent stoppings. Explosion doors are constructed at all fan houses to guard against injury to these machines.

MUCH ATTENTION GIVEN TO FIRST AID

It has been truthfully asserted that the most efficient safety device possible is a careful man. In order, therefore, to promote care and discourage carelessness on the part of every one, instruction in first aid has become one of the most interesting and important activities connected with the safety program of the Dawson mines. Every possible effort is being made to extend first-aid training.

In order to obtain maximum efficiency, classes have

Fig. 4—A Typical Safety Bulletin

After an accident an investigation is made and its cause determined. The accident is then reenacted and various pictures taken. These photographs form the nucleus of an effective safety bulletin. The one here illustrated is typical and shows "how Charlie Roman got his."

been organized among the several nationalities employed in these workings and residing in the various sections of the camps adjacent to the mines. These classes are in charge of competent, trained, local instructors assisted by interpreters. The course of instruction is covered in ten lessons of two hours each after which an examination is held and a certificate awarded to those showing the necessary proficiency.

Between Nov. 1, 1923 and March 1, 1924, 950 men, 33 women, 25 boy scouts and 80 school children completed the first-aid training as prescribed by the United States Government and passed the examination given by the officials in charge of Bureau of Mines Rescue Car No. 2.

Safety bulletins also are prepared from time to time by the engineering department and distributed about the works. Causes for the common types of serious accidents are studied, and photographs made at the working places, the subjects used being well-known employees. This lends local color to these bulletins (which usually takes the form of blue prints with photographs mounted thereon) and makes them highly interesting to the miners. They are eagerly studied when posted in conspicuous places such as the lamp house and check cabin.

All accidents are reported by the foremen, such reports giving the cause of the mishap and suggestions for the prevention of similar occurrences in future. These reports are filed for future reference and study. When fatal accidents occur, safety inspectors visit the scene and make a detailed study of all the conditions there existing. From the report then made a sketch is drawn by the engineering department showing the working place, the accident and its cause. Prints of this drawing are embodied in the report which must be made to headquarters. They are also used for the study of ways and means for the prevention of other serious accidents of a similar nature.

Posters executed in various colors are pasted on the sides of pit cars or locomotives and covered with a coat of white shellac. Some of the inscriptions used upon these posters are as follows: "Set that prop now," "Be careful of your eyes," "Take down that loose roof," "Don't let machine jack slip." These serve to admonish those who see them that they need to be constantly on the alert for dangerous conditions or practices.

FOREMEN'S MEETINGS PRODUCE GOOD RESULTS

In addition to all of these precautions, semi-monthly meetings for all underground foremen and assistant foremen are held regularly. At these "get togethers" various subjects are discussed including the general conditions of the mines, the improvements of existing rules, the formulation of new regulations, the causes and results of accidents and the hazards expressed by accident records. Improvement of working places and many other interesting topics are also considered. At certain specified times, usually three times each year, the underground foremen meet in joint session with those employed on the surface. All are interested in safety and first-aid work, and these meetings are usually of a highly instructive character.

Some of the more or less general rules which have already been formulated and are now followed are:

Not more than 1½ lb. of permissible powder may be placed in any one hole. Adobe dust is furnished at all working places and must be used for tamping holes.

Shooting off the solid is not permitted. All coal must be undercut and the bug dust or cuttings removed before it is shot down. All shots must be fired electrically, connections being made to the underground feeder lines by the shotfirers, who are required to report outside before the rounds may be fired.

Other rules are: All missed holes must be reported to the fireboss who temporarily suspends work at that particular place until conditions are made safe. Miners have nothing whatever to do with the use of either powder or caps. Only magnetically locked safety lamps approved by the Bureau of Mines may be used and these are in the hands of foremen, firebosses and shotfirers who have been thoroughly instructed in their use. Open lights are strictly forbidden in underground workings. All employees are searched frequently and without previous warning for matches or other smoking materials. Any found guilty of violating this fundamental safety rule against carrying such materials into the mine are liable to immediate discharge.

"Rome was not built in a day," and genuine mine safety cannot be attained overnight. For its accomplishment is needed time and unremitting application. This is the end kept constantly in view by the owners of the Dawson mines who are attempting to foster care and caution by all known means. Unquestionably much has already been accomplished, but continuous effort on the part of all hands along the lines above described should yield even greater results in the future.

Raton Coal Equal to That from Ohio

ONE of the most valuable coal deposits in the western states in quantity, quality, and accessibility of the coal is that of the Raton coal field, in Colfax County, N. M., situated in what is known as the Raton Mesa region, of Colorado and New Mexico, an area that measures about 90 miles from north to south, and 50 miles from east to west.

The bituminous coal in this region, which occurs in two series of beds, compares favorably in quality with the best bituminous coal of Ohio. Much of the coal of the lower series will coke, and at many places this coal occurs in thick beds that are easily mined. Coal has been mined in the Raton field on a commercial scale since the early seventies. The first large mines, which were near Blossburg, were operated for many years but were finally abandoned, as coal could be mined to better advantage at Koehler, Van Houten, and Dawson. Extensive mines have been opened recently at Brilliant, Gardiner, Sugarite, and Swastika. During the 10 years from 1911 to 1920 the Raton field yielded more than 27 million tons of coal.

Though the coals of this region are among the best in the West, their quality differs greatly from place to place. Most of the coal beds of the Raton field are relatively thick, contain excellent coal, lie almost horizontal and are not much faulted, but at some places the coal has been coked or completely burned out by intruded igneous rocks.

A description of the southern part of the Raton Mesa region, with maps, is given in Geologic Folio 214, issued by the Geological Survey, Department of the Interior, and the geologic structure of the coal-bearing beds of the Raton field is described in detail in the Geological Survey's Bulletin 752, Coal resources of the Raton coal field, Colfax Co., New Mex., just issued.

Survey Shows Big Percentage of Illinois Mines Generate Their Own Electric Energy

Steam Is Universally Generated—Return-Tubular Boilers Predominate—
Steam Engines Popular but Several Plants Have High-Pressure Turbines—
Seventy-Eight Per Cent of Mines Operate Private Power Plants

BY A. J. HOSKIN

Acting Head, Mining Engineering Department
University of Illinois, Urbana, Ill.

INASMUCH as Illinois is one of the largest of coal-producing states, the equipment at its mines probably is fairly representative of American coal-mining practice. Consequently, data I have collected showing what types and sizes of boilers, engines, turbines, direct- and alternating-current generators are used at many of these mines to supply power to both steam- and electrically-driven machinery will exhibit the general trend of power generation and supply at the mines of this country. We are at a period in all mechanical industries when efforts are continually being made to improve the efficiency of power generation and of power consumption. Many coal operators are not progressive, but some are outstanding in these matters and may be said actually to pioneer in their method of solving power problems. Many high- and mixed-pressure steam turbines recently have been introduced at Illinois mines. A few magnificent electric power-generating plants have been erected by coal companies, and these contain all the refinements of operation to be found in up-to-date public-utility plants.

The economic conditions in the coal industry are discouraging to many coal men and it is likely that most of the old mines will continue till they are finished with their present power units or with renewals of the same types. Operators of new mines, however, will equip their plants with more-or-less standardized apparatus. The data regarding Illinois coal mines which follow are restricted to shaft operations because such mines are

far more numerous than slope and open mines and their power requirements are always greater.

Steam is generated at all Illinois mines, even where none is used to drive machinery—as at the few wholly-electrified mines. When steam is not maintained in readiness to run hoisting engines, fan engines, tippie engines or pumps, or for emergencies at such mines, small quantities are nearly always required for heating buildings and to supply water for wash-houses. The steam requirements greatly vary and are largest for big companies operating plants that generate electrical power for distribution to groups of mines owned by one company.

Consequently, it is to be expected that boiler equipments will vary widely in capacity, type and efficiency. The return-tubular type predominates, it being used exclusively at about 78 per cent of the mines. At 8 per cent of the other mines it is supplemented by other types. At these mines there are, on the average, nearly six—actually 5.8—return-tubular boilers per mine, each of an average rated capacity of 145.5 hp.

At 14 per cent of the mines the boilers are exclusively of the water-tube type. Adding the 8 per cent at mines having mixed types, 22 per cent of the mines use water-tube units. These mines have as an average three such boilers each, their average capacity being 368.9 hp. per unit.

Illinois coal-mine operators utilize 7.6 times as many old-fashioned return-tubular boilers as modern water-

Switchboard for Steam-Turbine Plant

Many of the larger plants erected by coal companies have all the refinements found in up-to-date public-utility plants. Some plants use mixed-pressure steam turbines, getting the low-pressure steam from large hoisting engines.

High Voltage Transformer Substation Well Protected

From this bank of transformers power is distributed for the various operations in and about the mine. Choke coils and lightning arresters protect the transformers from any surges or other disturbances which may come over the power company lines.

tube boilers. Wherever water-tube units are in use, they have 2.7 times the capacity of the average fire-tube unit.

Interesting and varying opinions are entertained by Illinois operators regarding the value of the fuel they consume under their boilers. Some operators insist that their power fuel costs them nothing, it being grades of slack that command no market. Other operators carefully assess their power plants with their consumption of screenings or run-of-mine at the local current prices for these grades.

It is common practice at some mines to send to the boiler rooms any grades of coal that are not finding ready market. This occasionally results in the consumption at the plant of the better grades such as nut and lump. One operator frequently orders his lump coal sent to his boilers, his argument being that his lump costs him no more than does his slack. He thus takes direct issue with those men who claim that their fuel costs nothing.

OPINIONS ON POWER COSTS ARE DIVERSE

These diverse opinions are encountered when one endeavors to ascertain the relative costs of power generation at different mines. One superintendent will claim his power costs him nothing except the labor and a small item for supplies and upkeep, while a neighboring superintendent finds relief in accounting for a high coal-production cost by referring to his excessive power-generation expense which involves the combustion of good run-of-mine coal that has cost at least so much per ton.

Where water-tube boilers are installed, automatic stokers are invariably used. They are employed also at a few plants under fire-tube units. About one-sixth of the boilers are thus fired.

For the generation of electric power at the mines the usual motive power unit is the steam engine. The variety of these units well illustrates the progress that has attended the building of stationary engines during the past forty years. Some of them are strikingly interesting because of their antique features. On the other hand, there are some fine high-speed, straight-line engines and several of the Corliss type. A few of these are compound engines and operate condensing.

At about 62 per cent of the mines, engines are used exclusively for driving the electric generators. The average plant includes two engines, and it is the practice to assign each engine to a separate dynamo. Eighty-

five per cent of these engine-generator sets are direct-connected, 12 per cent are belted, the remaining few being either geared or rope-driven. The average generator capacity per unit is about 187 kw.

Steam turbines are used exclusively at only 4 per cent of the mines. These generally operate upon high-pressure steam. However, at one plant the power is derived from a mixture of live steam with the exhaust steam from a hoisting engine. The average capacity of a turbine and its built-in, alternating-current generator is a little more than 1,100 kva.

At about 12 per cent of the mines the generators are driven both by engines and turbines. Invariably the engines drive direct-current dynamos, turbines being used to drive alternators. At these mines the average capacities of these respective units are 177 kw. and 619 kva.

At the mines which generate all their electric power, which constitute 78 per cent of the entire number, the average generating capacity is 582 kw. Included in this summary are mines having all kinds of steam-driven generators. The average turbine has about 4½ times the capacity of the average engine. The average alternator has a rated capacity about 3½ times that of the average direct-current dynamo.

As it is in a class by itself, the magnificent power plant of the Standard Oil Co., at Schoper, is not included in the above generalities. In this plant there are two turbines of 4,000 hp. and one of 2,000 hp., each driving its own generator. The gross capacity of the equipment is 6,250 kva.

Electricity is used at every mine. Its sole use may be for illumination—as at a few ‘pick’ mines—and, in such cases, it is generally purchased. Some mines both generate and purchase electric power for the major operations, thereby eliciting an interesting economic inquiry. In the case of a mine that outgrows its power-generating capacity, one can readily understand why the owner might decide to purchase the necessary additional power rather than increase his plant but, when we find instances in which progressive operators have closed down their wholly-adequate powerhouses and are operating upon purchased electric power, we face a paradox.

OF THE ACCIDENTS CAUSED BY EXPLOSIONS, 40 per cent occur in the actual use of explosives, 40 per cent in their transportation and 20 per cent from suffocation by their fumes, stated J. E. Crawshaw of the U. S. Bureau of Mines in his remarks on “Explosion Hazards in Coal Mining” at a recent safety conference held in Pittsburgh, Pa. In 1921 about 40,000,000 lb. of permissible explosives were used in coal mines, representing only 18 per cent of the total consumption of explosives for this purpose. About 12 per cent were high explosives and 70 per cent were black powders. The use of permissible explosives and approved electric blasting equipment must be increased if greater safety is to be attained. J. J. Walsh, secretary of mines of the State of Pennsylvania, remarked that one of the laws scheduled for consideration at the next session of the Pennsylvania Legislature would compel the use of permissible explosives and electric blasting equipment in the mines of the state. The measure as applied to the anthracite field failed to pass two years ago. From present indications state-wide adoption is now probable.

Much High-Grade Material in Inferior Coals Which Sand Flotation Can Release

Many Coals Can Be Converted Into a Metallurgical and a Steam Product, Both Readily Salable—A Rise of One Hundredth in Specific Gravity Equivalent to an Increase in Ash of One per Cent

By H. M. CHANCE

Consulting Mining Engineer,
Philadelphia, Pa.

OUR low-ash coals are not by any means exhausted and may be obtained from many, and not, as is the general impression, from a few districts or from a particular bed or beds in that district. What promises a far greater supply may be found hidden in beds of relatively poor quality.

Coal is not a homogeneous material. No two lumps of coal are exactly alike. The distribution of ash throughout a coal bed is generally erratic and uneven. Layers and masses of high-ash and low-ash coal exist more or less irregularly intermixed in most coal beds. As everyone knows beautiful specimens of pure coal obtained from coal beds of poor quality are frequently used in promoting the sale of a coal property.

The problem involved in separating this pure low-ash coal from the higher-ash coal with which it is intimately associated is not unlike that of separating an ore, such as lead or zinc, from the rock or gangue matrix containing it, except that in ores the great difference between the specific gravities of the particles of ore and of the gangue of rock make their separation relatively easy. On the other hand, the difference in specific gravity between low-ash and high-ash coal is so small that the concentrating methods effect the separation of these two grades only with difficulty.

NOT NECESSARY TO CRUSH ALL THE COAL

The irregularity just mentioned, in the distribution of ash in coal, applies to coals of high grade as well as to impure coals. High-grade coals generally contain large percentages of phenomenally low-ash coal. The masses, layers or particles of such low-ash coal, however, may be of any shape or size; and a satisfactory separation generally can be effected without resorting to fine crushing of all the coal, the method that is so largely used in jigging coal for metallurgic coke-making. Low-ash and high-ash coal often are found together in lumps that to the eye appear to be of a uniform high grade.

The sand-flotation method of washing coal, by which an accurate separation of the coal into separate grades readily can be made, seems likely to add these widely distributed low-ash resources to our valuable low-ash reserves. The use of this flotation process depends on the following facts:

(1) The specific gravity of every piece of any particular coal depends on the percentage of ash in that particular piece, the specific gravity increasing almost uniformly about 0.01 for each per cent of ash. For example, if a coal with 3 per cent of ash has a specific gravity of 1.32, another piece of the same coal with 5 per cent of ash will have a specific gravity of 1.34; with 7 per cent of ash the specific gravity will be 1.36;

with 10 per cent of ash it will be 1.39 and so on. Apparently there are few exceptions to this rule.

(2) The distribution of ash in coal is quite generally erratic. Coal not being a homogeneous material, low-ash and high-ash coal may exist irregularly mixed through a single lump, which may appear to the eye to be homogeneous and of uniform quality throughout.

(3) The sand-flotation method separates materials on the "float-and-sink" principle; that is to say, it floats all materials lighter than the specific gravity at which the separation is to be made and all heavier materials sink. It thus virtually weighs every piece, large or small, floating only those that do not exceed a specified specific gravity.

The sand-flotation method was fully described in *Coal Age*, May 4, 1922, and it is not necessary to give again the details of the process. The number of plants now using this method, in the anthracite region, has increased to six, another plant is now under construction and others are being designed.

Each of these plants is owned and operated by a different company. They are widely distributed and no two of them are operating on exactly the same kind

Tank in Which Coal Floats and Refuse Sinks

Coal is subjected to the float-and-sink test, but the liquid in which the test is made is not densified by the use of soluble salts but by particles of sand suspended by mechanical agitation. The material heavier than a given specific gravity is, as popular parlance would erroneously state it, "sucked into the quicksand and swallowed up by it." Eventually it is drawn out through a valve lock and sent to the refuse bin.

of coal. They have a combined capacity of more than 1,000,000 tons annually. These plants are used not merely for the differential separation of the coal into two or more grades, but more particularly for the removal of slate, rock, fireclay, pyrite and heavy bony coal.

WHY COAL AND MINERAL PROCESSES DIFFER

From the zinc-lead ore parallel, referred to previously as an illustration, it is evident that the separation of masses of low-ash from a high-ash matrix is a process similar to that applied to ore dressing. To free ore from its matrix the material must be crushed; if the ore masses are large, coarse crushing is first used to recover the large pieces of ore. Similarly, with the differential separation of low-ash coal, when the coal contains relatively large masses or lumps of low-ash coal this should be removed before the coal is crushed to smaller size.

Here, however, the parallel ends, because the problem is not one of separating a very heavy substance from a much lighter material, as is the case in ore dressing. In treating coal it is necessary to separate all material having a lower specific gravity than that specified from that having a higher.

This can be effected by the use of high-gravity liquids, or high-density solutions, such as are commonly used in laboratory or experimental tests, but cannot be used in work on a commercial scale.

Table I illustrates the close relationship of the specific gravity of coal and its ash percentage, and shows the possibility of making differential separations of a coal into grades of different character. The data given are taken from the records of a series of tests on No.-2 buckwheat (rice) coal, which unwashed contained 34 per cent of ash.

Separation at a specific gravity of 1.90 gave 68.35 per cent of coal (floated), containing 10.10 per cent of ash and 31.65 per cent of refuse (sunk), containing 85.30 per cent of ash.

The refuse therefore contained nothing that could be classed as coal. The washed coal, containing but 10.10 per cent of ash, has a relatively low-ash content and is a satisfactory fuel for steam-making and other purposes. It does not, however, consist simply of particles of coal containing 10 per cent of ash, but is a mixture of particles having a range, in the percentage of ash, from 1.88 up to 39.85 per cent, as shown in Table I.

Table I—Showing the Composite Character of Coal

Coal tested was buckwheat No. 2 coal carrying 10.10 per cent ash

Specific Gravity of Liquid		A Coal, per Cent		B Coal, per Cent, Cumulative		C Ash, per Cent		D Ash, per Cent, Cumulative	
Less Than	More Than								
1.90	1.84	2.44	100.00	39.85	10.10				
1.84	1.80	2.25	97.56	34.07	9.35				
1.80	1.76	1.64	95.31	30.68	8.76				
1.76	1.73	1.96	93.67	26.54	8.38				
1.73	1.70	3.25	91.71	22.89	7.99				
1.70	1.68	2.05	88.46	18.58	7.47				
1.68	1.66	1.64	86.41	16.12	7.18				
1.66	1.64	0.48	84.77	12.63	7.01				
1.64	1.63	5.34	84.29	18.16	6.98				
1.63	1.61	9.54	78.95	11.43	6.22				
1.61	1.59	9.54	69.41	9.02	5.50				
1.59	1.57	11.44	59.87	7.05	4.95				
1.57	1.55	24.79	48.43	5.27	4.45				
1.55	1.53	21.36	23.64	3.29	3.58				
1.53	1.49	0.57	2.28	1.88	6.34				
1.49	1.71	1.71	7.82	7.82				
		100.00							

The analyses in Table I were made by George C. Davis, chemist, Philadelphia, Pa. If this coal is subjected to differential separation at specific gravities of 1.59, 1.57 and 1.55, respectively, the character of the two products yielded will be, approximately, as in Table II.

Table II—Showing Float-and-Sink Results

Specific Gravity of Liquid	Coal Floated, Per Cent	Ash, Per Cent	Coal Sunk, Per Cent	Ash, Per Cent
1.59	59.87	4.95	40.13	17.77
1.57	48.43	4.45	51.57	15.39
1.55	23.64	3.58	76.36	12.11

OUTCROP COAL MAY BE LIGHT BUT ASHY

Table I shows two apparent failures to follow the rule as to the relation of specific gravity to percentage of ash. The observed variations between gravities of 1.63 and 1.64 and results adjoining (Column C) was caused by the substitution of a new hydrometer, after breaking the one used in making the previous tests. Before the difference was discovered and adjusted, high-ash matter, which should have been distributed through the material separated at 1.66 and 1.68 gravities, was thrown into that separated at 1.64 gravity, thus increasing both the percentage of ash and the quantity separated at that gravity and reducing these items in the material separated at 1.66 and 1.68 gravities.

The other instance of variation from the rule appears in the separation obtained at 1.49 gravity, in which coal *lighter* than that separated at 1.53 showing 1.88 of ash, shows an exceedingly high-ash percentage of 7.82. This latter discordance is caused by the presence, in the coal tested, of a small quantity (1.71 per cent) of outcrop coal. This outcrop coal, though carrying 7.82 per cent of ash had its specific gravity reduced, by oxidation or partial disintegration, some 8 or 10 points below normal.

Bituminous coal has the same characteristics as is shown by these tests of anthracite. Its specific gravity is, of course, less; but, taking almost any bituminous coal as it is mined and shipped, and testing it by the method just described, it will be found to consist of lumps and particles varying widely in ash and in specific gravity.

Tests recently made on typical bituminous coking coals from Pennsylvania, Alabama and West Virginia show that products with less than 5 per cent of ash and sometimes less than 4 per cent can be obtained from coals normally averaging, as mined, from 9 to 15 per cent of ash. This result is obtained with less loss of combustible in the refuse, than occurs in jigging. Even when considering the most practical work in the washing of these coals by jigging, we find the products carrying from 6 to 10 per cent of ash.

When all of the coal cannot be recovered by this process and made an especially low-ash fuel available for metallurgic use, a differential separation can be made, at a specific gravity that will yield a suitably low-ash product, together with a higher-ash product that will not carry too much ash to prevent its satisfactory use and sale as a steam or domestic fuel. This will be found practicable in nearly all cases where the separation of the low-ash coal is effected without fine crushing.

In the application of the sand-flotation process to

the washing of bituminous coals, a feature worthy of mention is the reduction of crushing to a minimum, as the large lumps of low-ash coal are recovered without fine crushing. Furthermore the removal of fines made in the mining, handling and crushing of the coal before it is introduced into the machine, eliminates most of the troubles of sludge sedimentation and recovery by keeping this fine material dry. Another feature is the clarifying of the water for re-use, which is an advantage not obtained in washing bituminous coal by the methods in general use.

Glen Alden Uses All Available Pumps to Unwater Mines

River Water Entered at the Rate of Half Million Gallons per Minute—Will Take Nearly Four Months to Unwater Beds

THE engineers of the Glen Alden Coal Co., of Scranton, Pa., are making rapid progress unwatering several of their mines which were flooded April 7 when the Lackawanna River broke into the National mine near Taylor, Pa.

An investigation to ascertain the extent of the damage done by the flood disclosed that it was the worst ever experienced by any company in the anthracite field. About two years ago, rains and melting snow poured volumes of water into cave holes on the mountain side. On this occasion, the main pumping station at the Hampton Water Shaft was all but lost, the water rising several inches on the pumproom floor. Recently, when the Lackawanna River broke into the mines, the pumps were completely submerged.

The surface adjacent to the pothole where the river entered the mine was seriously creviced and caved and had been so for many years. The mine operations at this point are close to the surface and the hillside back of the old breaker is covered with many caves and potholes. A few years ago, there was a serious squeeze in this mine. Many acres of ground subsided, and several men lost their lives.

For years the anthracite mining companies have been building large breakers capable of preparing the out-

The Expensive Pothole

For many years nearly all the Glen Alden Coal Co. mines in and around Scranton have been interconnected in such a manner that most of the pumping can be done from one centrally located pumping station. The coal beds extend under the Lackawanna River and at many points run close to the surface, consequently a break under or near the river may cause the inundation of a large area of many mines and is always greatly feared.

put of several mines. As a part of this plan, the old breaker at the National mine, which is on the east side of the Lackawanna River, was abandoned and a tunnel was driven under the river to connect with the Taylor mine so that coal from the National mine could be prepared at the Taylor breaker. Knowing that the river bottom was close to the National mine operations at this point, the tunnel was made unusually narrow for double track, about 12 ft. wide.

Sometime ago, the earth over the tunnel a short distance back from the river's edge caved in and formed a pothole. The river, swollen by continuous rains, gradually washed away the earth between its bank and this point, and the ground finally gave way. Torrents of water rushed into the mine when the river turned its course into the hole.

For nearly two days the water flowed into the workings, part of the time at about 500,000 gal. per min. The natural drainage of the area is toward the Hampton pumping station about two miles away. Every effort was made to block the hole and stop the flood. Almost as quickly as bales of hay, bags of sand, timber, earth,

An Innocent Locking Pothole Cost a Fortune to Fill When the River Overflowed and Flooded the Mines

Mine cars, bales of hay, bags of sand, timber and rails were sacrificed to stem the flood. Unfortunately the ground in this vicinity is very loose and it was easy for the water to wash it away. Only large heavy materials would stay in the hole; many bales of hay and bags of sand were carried hundreds of feet into the mine. The picture gives but a faint idea of the quantities of materials used. Most of the water took a direct course to the Hampton Pumping Station where five 5,000-gal. centrifugal pumps were unable to handle the water quickly enough to prevent their submergence. About two to four months will be required to unwater the various mines affected.

mine rails and mine cars were thrown into the gaping hole, they were washed on into the mine. A fortune was lost in a few hours.

The Hampton pumping station is located in a natural basin in the coal beds, and here nearly all the water from about eight mines is concentrated and pumped a distance of 550 ft. to the surface by five 5,000-gal. centrifugal pumps, each driven by a 1,000-hp. motor. Under normal conditions, two of these pumps will prevent the water from rising, but just before the flood three pumps were required owing to an increase in the volume of water running into the pumping station from the mines located on the mountain side.

When news was received that the river had broken in, all five pumps were put in operation, and for a time it looked as though the discharge from the pumps was sufficient to prevent the water entering the pumproom. However, the pothole at the river was worn larger and larger, and finally dams and temporary obstructions set up in the mines were washed away. When the sudden rush of water came, two mine foremen at the Sloan mine nearby were trapped and drowned. The water being up to their waists, the pumpmen were forced to abandon the pumps, which they left running.

After the flow of water was checked, some of the engineers went to the pumproom, and after considerable difficulty and wading in water up to their necks they found all the equipment completely submerged.

Fortunately, the pumproom is located in the Clark bed which is some distance above the Baltimore beds. Although much of the river water found its way to these

latter they did not fill completely, and it is possible to drain a large quantity from the Clark bed to the lower beds, thus lowering the water so that the pumproom can be reached and cleaned out.

Material required to repair the pumps, motors and controllers has been ordered, but the repair work will be slow and difficult. In the meantime, pumping equipment has been transferred from other mines of the company and other coal companies in the immediate vicinity. It will take from two to four months to unwater the flooded areas.

The Hampton pumping station is the largest in the coal regions. Auxiliary power circuits were provided between the pump room and the company powerhouse nearby. Many protective features had been provided for the pumps and motors.

Such an important pumproom probably should have been surrounded with a wall or dam to prevent the water, even if it should rise higher than the pumps, from flooding the equipment. Perhaps it would be well to install more submerged-type vertical centrifugal pumps in the anthracite field, similar to those operated by the Hudson Coal Co. at a mine near Carbondale, Pa.

When the flooded area has been unwatered, much work must be done before it will be possible to resume mining in some of the workings. The rapid flow of water in the gangways has no doubt washed away much of the road beds, and tracks will have to be rebuilt. The timber which came through to the pumproom consisted of mine props and air stoppings along the haulage ways.

The Miner's Torch

Sameness

A SHORT time ago I was asked to make a little talk at a "Safety-First" meeting of plant executives employed by one large company and in introducing me the chairman stated that they had decided by way of variety to ask outsiders to address the meeting occasionally, which explained my presence.

His use of the word variety led me to ask some questions and I was surprised to learn that the different executives had reached a point where they felt that they had exhausted the subject of Safety-First so far as they were individually concerned, and for the life of them, they could no longer make talks that could be expected to hold the interest of their fellow employees.

It happened that only that day I had copied in my note book for future consideration the Bible quotation that reads like this: "There is no new thing under the sun" and the remarks of the foremen about having exhausted the subject under discussion reminded me of the quotation. Almost unconsciously I dismissed from mind the little speech that I had prepared for the occasion and ventured forth into a discussion of the Bible quotation. The impromptu talk that I made was received with so much interest that I have given the subject considerable thought since then.

It is possible to write about a single subject every day in the year and do it without repeating oneself and

do it in an interesting manner, both as concerns the one who is doing the writing and the one who does the reading. If you doubt this read the daily comments of the man who reports the stock exchange happenings for your daily paper; or again, consider that for over seven years now a certain newspaper writer has been giving us almost daily articles about conditions in Europe and they are just as interesting now as they were the day he began.

There is no new thing under the sun yet there are no two persons or things under the sun that are exactly alike. If you question that, talk with an employment manager who comes in contact with hundreds of men seeking work, or better still, take a walk in the woods and count the different varieties of leaves that you find there.

The principal difference between the man who can exhaust the Safety-First subject in one paper and the man who can prepare an interesting Safety-First bulletin every day in the year is that one has imagination and the other either lacks imagination or does not make use of it, generally the latter.

I have about reached the conclusion that whenever you find a man who cannot talk interestingly about his work you have found a man who has reached a state where he is no longer interested in it. Imagination and interest walk arm in arm; of course no two men have the same amount of imagination and no two men can inspire you with the same amount of interest by word of mouth, yet you are never left in doubt as to the inspiration a man finds in his work if you discuss his work with him.

Moral: When you have seen a thing from one angle you have not exhausted the possibilities.

"Balanced Mines" Should Have Rock-Bottom Costs

Waste Motion and Lost Coal Are Reduced and Loose Ends
Are Few Indeed Where the Whole Property Is Co-ordinated
All the Way from Hoisting Engine to Cutting Machines

BY CHARLES E. ANDERSON
Christopher, Ill.

AT EVERY mine inevitably arises the problem of putting its various parts—its workings, its equipment and its departments—in balance. Though it is entirely practical to design the entire operation so that each part will fit into a co-ordinate whole, this is seldom realized. The engineers about to open a new mine may try to strike such a balance, but companies with an old and poorly systematized mine too often think their cases are hopeless and that they must go on losing coal and paying too high a cost for what they do get. They should not be so helpless. There are ways in which such operators can put into proper balance the length of their panel entries, panels and partings and the size of their cars and tracks. These methods, properly applied, should reduce their costs.

What relation does the length of panel entry have to the length of a parting on the main-line haulage? What relation has it to the length of loaded and empty tracks on the main bottom? What relation has it to the size of locomotives in use, both gathering and main line? What relation to the size of steel on the haulage roads has it? How can we determine what size the shaft should be, the size of the hoisting ropes, the height of tippie and size of hoisting engines?

These vital questions can be answered correctly in every case by a simple analysis of the local conditions. It is taken for granted that in locating the shaft of a new property, boreholes have been sunk and levels run on them, thus giving the loaded cars the advantage of the dip. Of course, other considerations enter into location of the hoisting shaft, the most important being the necessary space for loaded and empty railroad cars and the grades for handling them.

In machine mines, the cutting machine is the basic factor with which to begin. The panel entries should be just long enough to provide a full machine run on each panel and still leave a sufficient barrier pillar. In some sections there is an agreement between the operators and miners' union that arbitrarily sets the number of men that a machine may cut coal for, and in such cases the length of panels should be governed by this number.

We will say that fourteen men constitute a full com-

plement of men for a machine. Then fourteen rooms will be necessary. Owing to the condition of the roof it is found that the rooms should be opened at 50-ft. centers, and that a barrier pillar 125 ft. thick must be left. We must provide panels having a total length of 800 ft. in order to obtain space for fourteen rooms on 50-ft. centers and leave the desired barrier pillar. Thus we have established the proper length of panel.

As a panel has fourteen rooms, and as the men work "double," seven-car trips are required in order to give a turn of one car to each pair of men. There being one full machine run on each panel, and twenty-eight men on each pair of panels, one gathering locomotive will be needed to care for each two pairs of panels, having fifty-six men assigned to it, or four full machine runs. This requires space for twenty-eight cars on the parting for both loaded and empty tracks for each locomotive so used. Should there be two locomotives working

HOW "MINE BALANCE" AFFECTS COSTS

WHAT does it cost a mine owner to have his mine "out of balance?" A little study of each property so afflicted will convince the operator that the costs are heavy. He can find lost motion everywhere and lost motion is costly. He can find machines and loaders tied up in one section for want of transportation while a motor is wasting time handling ridiculously small trips in and out of another section where machines are few. He can find much inequality in distances between workings and partings. He can find some partings always congested while others have unused space expensive to construct and maintain. He can see the top coming down or the floor coming up on pillar coal and even on room coal that could have been recovered if the workings in that part of the mine had been operated in unison, under a proper system. Hence the need for mine balance.

on the same parting with a full complement of men, and an additional locomotive pulling from the men that are working the heading for development, space will be needed for fifty-six cars for the two locomotives having four full machine runs, and fourteen additional cars for the heading men, making a total of seventy cars. Under this system it will be found that an equal turn of cars will be pulled for all the men in the section.

At one mine working under this system there was a fairly good bottom and 8 ft. of coal was being taken. The operators planned on hoisting 5,000 tons per day of eight hours; so it was decided to use as large cars as possible, keeping in mind that the men must push the empty cars into the working face from their room switch. The management consequently decided to use a 5-ton car, having roller bearings and 20-in. wheels. It was found that the car would have to be built 10 ft. long and 24 in. high to hold that quantity of coal. The gage of the track was 42 in., this width being chosen because the company had much equipment of this gage available. As they had decided upon a 10-ft. car it was necessary to have 700 ft. of empty and loaded space on the parting in order to provide room for seventy cars.

Having decided upon a 5-ton car, and having to han-

Fig. 1—On This Type of Panel, Gathering Motors Serve More Men Than Is Customary in Most Mines

Locomotive goes into one panel entry to leave empties spotting them at the mouths of the rooms and then switches to another to get loads.

dle seven-car trips over a maximum grade of 3 per cent in the panels, the size of the locomotive necessary was found by using the following method, suggested by a statement made by J. T. Beard, "A tractive effort of 30 lb. per ton is required to haul a load on level track, together with 20 lb. per ton additional for each per cent of grade." The maximum grade being 3 per cent, the net load 10,000 lb. and the weight of a car 3,500 lb., the necessary drawbar pull for a seven-car trip is found to be $7(30 + 60) (10,000 + 3,500) \div 2,000 = 4,252.50$ lb.

Again quoting J. T. Beard: "The tractive effort of a locomotive having steel-tires is 25 per cent of its weight, plus 10 per cent if sand is used." The weight of the locomotive needed to pull the trip, therefore, is $4,252.50 \times 4 = 17,010$ lb. or approximately $8\frac{1}{2}$ tons. As the maximum grade is never of great length, advantage was taken of the 10-per cent allowance for sand and 8-ton locomotives were installed. They have been found to be of ample weight.

The size of steel for the panels was found by the following rule, also given by J. T. Beard: "The weight of rail in pounds per yard necessary for a given weight of locomotive is found to be ten to sixteen times the weight in tons, on each of the drivers, where four drivers are used." So we have $16 \times 8 \div 4$ or 32 lb. per yard, so 30-lb. steel was installed. This also has proved sufficient.

MAIN LOCOMOTIVE TO HAUL 35 CARS EACH TRIP

The main-line locomotives will be required to haul in a single trip from the inside parting as many cars as the two locomotives gathering from rooms will bring to that point in two trips and one locomotive gathering from the headings will bring in one trip. Thus the main locomotive must be expected to haul at each trip five gathering trips of seven cars or thirty-five cars. As the main bottom to accommodate the main-line locomotive must provide space for two full trips of empty and an equal number of loaded cars, space will be needed for 140 cars, or seventy on either side. As the mine under discussion uses cars that are 10 ft. long, both loads and empties will require 700 ft. of track. Add to this length the needed space for diamond switches or other equipment to be installed, and the total required length of the main bottom is established.

The weight of the main-line haulage locomotive can be found in exactly the same manner as that of the gathering locomotives. In this mine, most of the main entries were either level or favorable to the loaded trips, but some gradients slightly exceeding one per cent had to be left against the loads. Using the same method as before the drawbar pull $= 35(30 + 20) (10,000 + 3,500) \div 2,000 = 11,812$ lb. $= 5.906$ tons or

the draw-bar pull necessary to haul the thirty-five car trip over the maximum gradient along the road which is one per cent. Allowing the locomotives 25 per cent of their total weight for drawbar pull we have $5.906 \times 4 = 23.624$ tons which is the necessary size of locomotive to handle the trips over this grade. Twenty-five-ton main-line locomotives were installed and they have proved satisfactory.

The weight of steel for the main-line track was computed in the same way as that for the inside locomotives, except that a smaller factor was used in this instance. Using the factor of ten instead of sixteen we have $10 \times 25 \div 4 = 62.5$ lb. per yard. Sixty-pound steel was installed with perfect satisfaction.

The advantages of such a system are at once apparent. There is no lost motion in this plan, except that the mining machines are limited to fourteen men. This cannot be overcome until actual tests have been run and new agreements made. The number of men on a machine can be increased to eighteen and still be taken care of under this plan, simply by adding a little to the weight of the haulage locomotives and the track.

MORE MEN SERVED BY GATHERING LOCOMOTIVE

The number of men served by the gathering locomotives will be seen to be considerably higher than is generally found in most mines, but let us analyze it. (Fig. 1.) We will number the machines being served by one locomotive Nos. 1, 2, 3 and 4. Nos. 1 and 2 are located on the 3rd and 4th East panel, and directly across from them are Nos. 3 and 4 in the 3rd and 4th West panel.

The locomotive will take seven empties and spot them in the 3rd East panel for machine No. 1, proceed through the last angle crosscut near the face of the panels and gather seven loads from machine No. 2 in the 4th East panel, leaving No. 2 gang without empty cars for the time being. Having placed these seven loads on the parting, the driver will now take seven empties into the 3rd West to machine No. 3, and again go through the last angle crosscut and pick up seven loads from machine No. 4 in the 4th West panel.

Putting these loads on the parting he will go into the 4th East panel with seven empties to machine No. 2, cross through into the 3rd West panel and gather up the seven loads there. After depositing these on the parting he will return seven empties to machine No. 4 in the 4th West panel, pulling machine No. 3 in the 3rd West panel as he comes out, thus completing his turn of singles to the four machines.

This has required him to make four trips, and as he should not get less than ten tons per man, he will be required to make a total of sixteen trips in order to get the proper quota from his territory. This gives him a full half hour to make each trip. It will be

Fig. 2—Cross Entries Should Be Turned So That Panel Entries Will Face on Either Side

Each entry has length enough for fourteen rooms and a barrier pillar 20 ft. thick. The rooms are set on 50-ft. centers.

found that he can do it in less time and that he will average twelve tons per man or more. By this system the gathering locomotive driver will be required to gather 112 cars to complete his proper day's work, which will give a total of 560 tons per locomotive so used. As a matter of fact some of them actually average 125 to 140 cars per day. The effect upon the haulage costs readily can be seen.

There is another point to be considered in connection with the length of the panels. It is the recovery of the pillars, one of the most important features of mining, yet one that is sometimes sadly neglected. There is a great difference between extracting pillars in live workings and extracting them in workings that have been standing a long time. Where all the rooms are driven up together and work is started on the pillars immediately after they have been driven their proper distance, it is possible to recover a larger percentage of the pillars if due care is taken to concentrate the work so that a "break" can be obtained at the proper place and the weight relieved.

When more places are turned on a panel than the machine can cut, there are just that many rooms standing while the rest are driven up. The laggards are bound to take weight and many of them will cave so high that no pillars can be drawn. Under these conditions every attempt to extract them fails, and sooner or later it is decided that the pillars cannot be recovered in "this particular mine" and the effort is not renewed.

Owing to the varying conditions in each field of mining, no set rule for recovering pillars, of course, can be given, except that the work must be so conducted that the roof will be made to break and relieve the weight. However, no case has ever come to my attention where pillars were drawn successfully unless the work was done immediately after the rooms were driven up.

The length of the panel entries also determines the distance between cross-entries (see Fig. 2). These should be turned so that panel entries can be driven on either side. Consequently, twice the length of the panel entries plus enough to leave a small pillar, where it is not advisable to hole through, gives us the proper distance for turning the cross-entries. In the case cited above, where there are fourteen rooms on 50-ft. centers, panel entries are 800 ft. long. To find the proper distance to turn the cross-entries we have $(800 \times 2) + 20 = 1,620$ ft. A rigid following of this rule will keep all sections of the mine balanced.

Except in mines that are nearly finished, the workings can be re-arranged so as to conform to the system outlined and to co-ordinate each department. Where rooms have been turned in the panels indiscriminately as fast as they were reached nothing can be done except to work them out in the best way possible and get

out of them; but in all new work the plan described can be followed by simply rearranging the system to conform to the general outline given.

The following instance is a shining example of correcting old workings. The cross-entries in a certain mine were turned so that there were thirty-three rooms on the panels between entries and barrier pillars of 125 ft. The men constantly made it a practice to turn rooms on the panels as fast as they came to them, so that they had room for only one machine in a panel at one time.

In one case miners reached room No. 25 and holed into workings of the same panel being driven to meet it from the next cross-entry. There were only eight rooms on that side, the first two being driven up to the full distance. The next rooms were nearly done, while the rest were shorter as the point where they holed was approached. All switches were turned

so that all the coal was taken out through the cross-entry farthest from the shaft, and pillar work started in room No. 4, counting from the side nearest the shaft.

The first three rooms in the cross-entry had caved so high that none of the pillar coal in them could be drawn and all this part of the work was showing weight badly. Before all the first pillar was recovered a squeeze started that extended through all the finished rooms, and part of the rooms that were being extended. One machine was taken out of the territory and as the remaining machine drove the rooms next to the squeeze up near their distance, the

squeeze would start and run the men out of other rooms as well.

To correct this condition the next pair or cross-entries was made twice the length of the panels, plus 20 ft. The first pair of cross-entries was stopped entirely, and the second pair was converted into main entries on either side of the mine, new cross-entries beyond all development were driven through between them, and panels driven from these.

In the original plan, the men drove the main entries east and west, cross-entries north and south, and panels parallel to the main entries. Only the second pair of cross-entries on either side had been turned when the company decided to make the change.

In the new east and west development the original plan was followed but the distance between cross-entries was made to conform to the fourteen-room limit. That was simple, but in the north and south development the mine had virtually to be turned around. The first pair of cross-entries on either side was stopped, and the second pair on either side was converted into main entries. Cross-entries were driven through between them, from the 3rd and 4th South on the East, to the 3rd and 4th South on the West and panels were turned at regular intervals to the South from these.

WILL THIS SAVE SOME "DOOMED" HIGH-COST MINES?

THE number of men following each cutting machine is a basic element in laying out the system by which the mine is worked. Because someone didn't realize this, who operated a mine with fourteen-man units and tried to operate panels having thirty-three rooms, he lost much recoverable coal and spent a good deal of money to revise his system. However, in many an old and high-cost mine, the erratic plans can be revised as Mr. Anderson outlines in this article. A careful study of conditions and the adoption of a system similar to the perfectly balanced one described here, might help to keep certain mines in this country working during the coming year which now appear to be doomed. The subject of "mine balance" therefore is worth consideration.

New cross-entries were driven between the old ones when the new south mains had progressed far enough. The balance of the development conformed with the rest of the work. The layout was made the same way on the north side, and a model mine was the result.

All these changes were necessary because somebody overlooked the fact that fourteen men constituted a full complement for a machine at that mine. The size of the machine units was set by agreement between the company and the miners' union, yet thirty-three rooms were turned on the panels instead of fourteen.

To balance some other features of a mine a little care is also necessary. The length of the car will determine the width of the shaft, and the proper allowance for the buntons, guides and cages, and for the space needed for pipe and wire work will determine its total length.

The weight of the cage, plus the weight of the car will show the proper size of the hoisting rope by following this rule: "Add the total weight of the cage and loaded car. Multiply this by 7—the factor of safety—and divide by 50 (if the sum so obtained is above 50, whereas if it is below 50 it must be divided by 40). Finally extract the square root of the quotient." This

is the diameter of a plow-steel rope, having six strands of nineteen wires to the strand.

The height of the tippie is governed by the number of grades of coal that it is desired to make and upon whether gravity or mechanical screens are to be used, but I will not enter into a discussion of this question in this article.

The total weight of the coal to be hoisted—the cages and cars balancing each other—multiplied by the speed per minute, and divided by 33,000 will show the necessary horsepower of the engine. Friction of ropes and cages will also have to be added, and this figure will also show the power of the boilers necessary, unless other equipment using power from them is to be installed.

Thus it is shown that everything about a mine can be balanced and each department must be co-ordinated with all the others if lost motion is to be avoided. The general efficiency of the mine is affected by the efficiency of each department, and many times coal is mined at too high cost to be profitable because one or two departments are not functioning properly. Only a proper analysis will show where the trouble lies and relieve this situation.

Use of Rescue Apparatus and Gas Masks Increasing

One Hundred Apparatus Men at Recent Mine Explosion—Gas Mask Safe Where Enough Oxygen Is Present to Keep Safety Lamp Alight

INSURANCE companies, by offering a reduction in premium for each trained first-aid man employed by a mining company, are endeavoring to increase the interest of coal companies in first aid, said D. J. Parker of the U. S. Bureau of Mines in an address before a safety conference called at Pittsburgh on the occasion of the visit of two delegates of the British Government recently. In an address on "Developments in Mine Rescue and First Aid" Mr. Parker said that Dr. Holmes' dream of the spread of privately owned rescue apparatus is beginning to be realized. At a recent mine explosion in western Pennsylvania there were 90 trained apparatus men from near-by operations and only 10 from the U. S. Bureau of Mines, making what is believed to be the largest number of trained and equipped helmet men that has ever participated in rescue work following a mine disaster.

A. C. Fieldner followed with a talk on the "Use of Gas Masks in Mines," outlining the application and limitations of this equipment. Atmospheres in unsealed burning mines may, or may not, contain enough oxygen to support life and if they do not, a gas mask is valueless. It will change carbon monoxide to carbon dioxide so that the wearer will be saved from a death by poisoning only to die by asphyxiation. That the air in open mines with burning areas may be so greatly depleted of oxygen as to be irrespirable is a conclusion that has been reached by a research fellow at the Pittsburgh station of the Bureau who has been investigating that subject.

J. J. Walsh, state secretary of mines of Pennsylvania, said that the return air from five fires in anthracite mines on analysis was shown to contain 16½ per cent or more of oxygen. In three of these mines safety

lamps would not burn. This led State Inspector Richard Maize to say that gas masks were of little value if they could only be used where safety lamps would burn. The reply was that in case of a mine fire the suitable action of a safety lamp did not assure that conditions were safe, for such a lamp will burn in a percentage of carbon monoxide that would be speedy death to anyone breathing it.

Mr. Maize then asked what percentage of carbon monoxide in a mine atmosphere would make the use of gas masks dangerous. Mr. Fieldner replied that the limitations of the gas mask are fixed by the intensity of the heat generated. Enough heat is evolved in the canister by the oxidation of a 6 per cent mixture of carbon monoxide to melt the canister. Mr. Cotts of the Bureau remarked that a safety lamp cannot be burned in an atmosphere containing more than 2 per cent of carbon monoxide. A safety lamp will burn in a 2 per cent concentration. In such atmospheres a self-rescuer gas mask has been worn for 20 minutes. A number of samples taken in fire zones show that the quantity of carbon monoxide in the atmosphere is usually less than 1 per cent. Mr. Cotts declared that a gas mask will give proper protection wherever a safety lamp will burn.

Henry Walker, deputy chief of the Mines Department of Great Britain, said he was surprised to hear that 1,600 gas masks were available for use at United States mines. He added, "I didn't know that gas masks were in industrial use." Dr. J. J. Rutledge said that every state inspector in Maryland is equipped with a "self rescuer" gas mask.

THE HILLMAN COAL & COKE Co., sets a good example, continuing its plan of electrifying its old steam-equipped mines one by one, not delaying the program because of low coal prices. The job continues according to a schedule long ago determined. Low prices of coal do but make such economies the more necessary, cost of coal replacing volume of output as the essential element of profitable operation.

News Of the Industry

Coal Transportation in Foreground At National Capital

**Influences Work to Spread Movement Evenly Over Year—Lack of Orders
Now a Stumbling Block—180,000 Coal Cars Available—Inability
to Control Supply to Inefficient Operations an Obstacle**

BY PAUL WOOTON
Washington Correspondent of *Coal Age*

With hearings in progress before the Interstate Commerce Commission on the Lake cargo rate case; with mine-rating and car-distribution rules about to be taken up for the consideration of proposed revisions and with Sec. 28 of the Merchant Marine Act under debate on Capitol Hill, matters involved in the transportation of coal promise to be on the tapis for some time to come. In addition, strong influences are at work in an effort to spread the coal movement as evenly over 1924 as was the case in 1923. *Railway Age* is alarmed by the recent abnormal decline in coal shipments and declares editorially that "if the present low rate of production continues, there later will be an abnormal increase in production and in demands upon the railways for transportation. This abnormal increase in the demands upon the railways will cause congestion in the handling of all traffic and abnormal and unnecessary operating expenses that the shipping public will have to pay."

First Move Up to Shippers

The editorial then proceeds to advise a resumption of shipments, but it places the burden of the obligation upon the shippers. The fact that shippers cannot ship until consumers place their orders seems to have been overlooked, as is indicated by this extract from the editorial:

"One of the principal reasons why the railways were able in 1923 to handle a record-breaking freight business without car shortages, congestions or delays, . . . was that shippers gave their freight to the roads in unprecedentedly uniform volume throughout the year. Fearing that there would be a car shortage when the peak of business was reached in the fall, many shippers . . . heeded the injunction to ship early."

"The movement of freight in 1924 already has been subjected to wide fluctuations and the seasonal fluctuations threaten to become as great this year as in years previous to 1923 unless more shippers can be aroused to the desirability of shipping early and avoiding the usual fall rush."

There has been no time in a decade that the producers of coal would rather

ship than at present. If some means can be devised to convince consumers that they should make purchases at this time, the producers would be as pleased as would the railroads were it possible to put into immediate service the 180,000 coal cars now standing idle.

There was advance announcement, and it has been reiterated frequently, that no adjudication of the Lake cargo rates would be made in time to have a bearing on this season's movement. For that reason it cannot be ascribed as a cause for the slowness with which the Lake business is getting under way. In February the Interstate Commission gave ten days of its time to hearing the complaint of the Pittsburgh and Pittsburgh No. 8 operators, who are seeking a widening of the differential between the short-haul rates from the Pittsburgh district and northern Ohio to Lake ports and the long-haul rates from West Virginia and other Southern fields.

After a recess of two months, the commission on April 22 resumed the Lake cargo hearings. As this is written the railroads are putting in their testimony. These witness will be followed by those of the Southern operators.

Judging from the evidence which has been taken thus far, it would seem that there is going to be great difficulty in proving that the long-haul rates are unreasonable. On the other hand, there is increasing reason to indicate that cuts more properly could be made in the short-haul rates. This is having the effect of lining up the short-haul roads against the Pittsburgh operators.

Of scarcely less traffic interest are the proposed changes in mine ratings. There is sharp cleavage between the coal operators on this question. Generally speaking, the larger operators favor the proposed changes which are avowedly aimed at the inefficient and uneconomical mine. Their feeling is that the consumer who contracts for his coal should be protected as against the consumer who does not provide in advance for his fuel. As it is, contract buyers, during periods of car shortages, frequently cannot get deliveries on their contracts because the mines of less efficiency come into production and dilute the car supply.

Kelvin Medal for Thomson

Elihu Thomson, one of the founders of the General Electric Co. and director of the research laboratory at the Lynn (Mass.) works, sailed for Italy, April 26, to be gone three months and tour several European countries. In England he will receive the Lord Kelvin gold medal, being the first American to be so honored. The medal award was established by British and American engineering societies.

The principal obstacle to the change seems to be a legal one. There is grave doubt as to the legality of denying transportation to a shipper because that shipper did not furnish tonnage during a period of car surplus. There are other objections, however. Some fear that the proposed rule would result in the sale of a large amount of coal at cost or even below in the effort to build up a commercial rating which would permit comparatively large shipments during the car-shortage period. Not only would this inject a new inducement to the speculator but some fear that it would give an additional advantage to the non-union mine.

Could Nullify Assigned-Car Ruling

With their longer operating time, it is feared that the non-union properties could build up a commercial rating which would give them an undue proportion of the cars during an emergency. It is thought in some quarters that the proposed rule would nullify any advantage which has come from the victory in the assigned-car case. The railroads as the largest single body of consumers would be in a position to get most of their coal again at cost because of the desirability of establishing a better commercial rating. The producers then would have to look to other consumers for all of their profit.

Much is being made of the contention that such a rule would give a federal bureau an important control over commercial transactions. It would make it necessary for the commission to take judicial notice of union and non-union mines.

Many hold the opinion that the railroads now are so well supplied with equipment and have their properties in such good condition that they will be able to continue to meet practically any demand that is put upon them. The policy of the railroads to require each line to own enough equipment to protect all freight originating on it is bearing fruit and is an important factor in the prevention of car shortages.

M. F. Burns Dies Suddenly At Age of 70

Michael F. Burns, president of the retail coal firm of Burns Brothers from its organization until his retirement, April 8, died suddenly last Monday at his home in New York City. He was about 70 years old. Mr. Burns had been one of the leading men in the retail coal industry of the United States for a generation.

From time to time during the last two years there was talk of a change in the management of the company, but nothing came of it until Mr. Burns presented his resignation, March 12, last, to become effective April 1. On April 8 the board of directors accepted Mr. Burns' resignation and appointed his son, Frank L. Burns, to the presidency of the company and elected the elder Burns chairman of a newly created advisory committee.

Shortly after the World War, at the time of the widespread discussion of high coal prices, Mr. Burns testified before the Senate committee investigating the situation. He stated that his company had made a profit the previous year of \$1,200,000, and would earn \$1,500,000 the succeeding twelve months. He said his own salary was \$50,000 a year. Mr. Burns also was a director of the Coal & Iron National Bank of the City of New York, president and director of the N. Y. & N. J. Real Estate Improvement Co., and a director of the U. S. Distributing Corporation. Mr. Burns was a widower.

"Serfdom" of Miner Is Past Says Civic Federation

Extracts from a survey made by the Department on Current Economic and Political Movements of the National Civic Federation into industrial, social and civic changes during the last several decades show some interesting sidelights on conditions in many industries.

In the preliminary report presented to the Federation at its meeting in New York City, on April 24, John Hays Hammond, chairman of the department, stated that the survey was taken to ascertain just what "lies back of the claims of the apostles of gloom that our country is going on the rocks."

The first field explored was that of "Labor," and the department appealed to the 115 national organizations affiliated with the American Federation of Labor, as well as to the railway brotherhoods, "with results a little less than astounding," says the report.

After setting forth wages in transportation lines, needle trades and other lines of industry the report has this to say of the mining field:

"Take the workers in the coal mines, comparing their conditions and wages back in the '80's and even the '90's with those of today. The following extract from the report of the A. F. of L. proceedings at its 1902 convention throws some light on this:

"For more than twenty-five years the conditions of the miners had continually deteriorated. Many of the miners had been often supplanted by

Mine Bosses and Foremen Liable for Gas Blasts

Mine bosses and foremen may be charged with manslaughter if coal miners lose their lives through failure of their superiors to prevent gas explosions, according to a decision by the Oklahoma Criminal Court of Appeals at Oklahoma City. The opinion was delivered in affirming the conviction and sentence to one year's imprisonment of Martin Clark, a pit boss in a Latimer County (Okla.) mine. Clark was on duty when an explosion killed ten men in the mine Aug. 21, 1920. The boss was found to have been negligent in taking proper precautions to warn the men of the presence of noxious gases in the mine.

others, and through a system of espionage, victimization and company stores, their organization was destroyed. No protection was, therefore, afforded to the miners to check the power and avarice of the mine owners. The misery and poverty obtaining in the region surpassed all descriptions disclosed during the contest of 1900. The miners were veritable serfs of the companies: they were unable to leave the region by reason of their never being in possession of current money."

"Take the case of the anthracite common and outdoor laborers, where, in 1895, drivers were getting \$1.10, furnace firemen, \$1.05, steam pumpers \$1.15 and so forth, and where in 1900 they worked only 150 days a year. Then consider that the recent anthracite contract, covering all the miners, gives 270 days of work and a minimum of \$4.62 for an 8-hour day. The contract miners receive a great deal more, frequently reaching the building-craft standard."

Henry Wants a Dock Now

The latest prospective purchaser for the 600,000-ton dock of the Superior Coal & Dock Co. at the Head-of-the-Lakes is none other than Henry Ford. In fact the deal has progressed so far that Mr. Ford has made a definite offer for the property of an amount sufficient to cover the investment value of the property, but there are certain obstacles to the sale which may be eliminated soon. If they are overcome, by midsummer Mr. Ford will have docking facilities which will be of value to him in handling coal produced at his own mines and hauled to the Lakes on his own rail lines for consumption by his own huge power plant at the Twin Cities. The Superior Coal & Dock Co. is a subsidiary of the Maynard Coal Co., now in the hands of receivers. The dock has been offered to various dock interests without awakening any interest.

Lull Before a Storm in Straight Creek Region

It is beginning to look like a lull before a storm at the plant of the Liberty Coal & Coke Co., on Straight Creek, near Pineville, Ky. There has been no shooting since April 3 but a good deal of ill feeling against the state troops has been worked up by men who refused to work at the reduced scale of wages. Evictions from company houses are due April 30. This may result in another flare-up.

On April 16 Frank Daugherty, State Attorney General, ruled on a request from Adjutant General Kehoe, holding that the Kentucky National Guardsmen could not be used in eviction of occupants of company houses, as they had no authority in the matter. Kehoe had informed Daugherty that in his opinion disorder was caused by persons illegally holding company houses and who had violated their leases with the company. Kehoe wished to know whether guardsmen, in order to prevent lawlessness, could legally arrest such persons as trespassers and subject them to forcible eviction.

Daugherty pointed out that the company had recently obtained a federal injunction prohibiting interference with its operations on the part of strikers, and as a result of that injunction the company must appeal to the federal court for relief from any violation of the injunction.

Keystone Employees Accept 20 per Cent Wage Cut

A 20-per cent wage reduction by the Keystone Coal & Coke Co., the largest independent fuel operator in Westmoreland County, Pa., became effective April 24. The cut is general, including all employees from day laborers up to coke drawers. Between 8,000 and 10,000 men are affected.

The Keystone company is operating on a three-day and four-day schedule at its plants, all men getting half-time or over each week. Inability to continue operations at the old wage scale was given as the reason for the reduction.

The men are taking the cut without complaint and full crews reported at all plants.

Coal Consumption by Utilities Drops; Power Output Up

Electric public-utility plants consumed 3,374,384 net tons of coal during February, according to a report just issued by the Geological Survey. This compares with 3,673,447 tons consumed in January and 3,394,877 tons in December. Fuel oil consumed by utility plants in February totaled 1,546,289 barrels, compared with 1,602,745 barrels in January and 1,472,946 barrels in December.

The average daily production of electricity by public-utility power plants during February was 168,300,000 kw.-hr., which exceeded all previous records, being slightly higher than that for January.

Accidents at Coal Mines
Killed 339 in March

Accidents at coal mines in the United States during March, 1924, killed 339 men, according to a report by the U. S. Bureau of Mines. Included in this number are 172 fatalities caused by an explosion at Castlegate, Utah, on March 8, and 24 fatalities resulting from an explosion on March 28 at Yukon, W. Va. The fatality rate for the month was 7.06 per million tons, based on an output of 48,023,000 tons, as compared with 2.69 in the previous month and 3.26 for March last year, based on a production of 56,184,000 tons of coal. During March, 1923, only one major disaster, a coal-dust explosion, occurred, resulting in the loss of 10 lives.

During the first quarter of the present year 750 men have been killed by accidents and 160,094,000 tons of coal have been mined, the fatality rate being 4.68 per million tons. During the corresponding period last year 692 lives were lost, the production of coal was 165,008,000 tons, and the fatality rate was 4.19. For bituminous mines alone, the fatality rate for 1924 to the end of March was 4.60 per million tons, as compared with 3.95 for the corresponding months of 1923; for anthracite mines the rate per million tons was 5.16, as compared with 5.49.

Explosions of gas and coal-dust and accidents by explosives show an increased fatality rate per million tons in 1924 as compared with the first quarter of 1923. Substantial reductions are shown in the fatality rates for falls of roof and coal, haulage ac-

W. W. Inglis

In a statement to a representative of *Coal Age*, W. W. Inglis, president of the Glen Alden Coal Co., declared that the work of preparing for operation the four Glen Alden mines recently flooded by the Lackawanna River will require nearly two months. One million gallons of water is being pumped from the operations daily, three shifts of workers being employed. The loss in production of hard coal is estimated at 2,000 tons a day.

cidents, and accidents due to electricity, as indicated by the following figures:

Report Shows Kentucky
Coal Is Taxed Aplenty

A report of a special commission to investigate coal-land taxation would indicate that Kentucky coal is now taxed aplenty, and that the defeat of the coal-tonnage bills in the General Assembly of 1924 was no more than just. The special commission with an appropriation of \$20,000 for 1922 and the same amount for 1923, made a report to Governor Fields which was made public on April 23.

The report showed that coal-land assessment had been raised 43.2 per cent in four years, and, according to John B. Lewis, chairman of the tax commission, may be increased in some counties next year. The increase in agricultural counties in the same period was but 7.1 per cent.

According to the report, during the four years the total (land, mine equipment and improvement) in coal-bearing counties shows a rise of 47.7 per cent.

Eighteen counties produce 85 per cent of the coal mined in Kentucky, with the following percentages of assessment increase in 1923 over 1919: Bell, 12.5; Clay, 17; Floyd, 102; Harlan, 90; Hopkins, 8; Johnson, 43; Knott, 52; Knox, 16; Laurel, 7; Leslie, 19; Letcher, 112; Muhlenberg, 29; Ohio, 31; Perry, 136; Pike, 102; Union, 9; Webster, 4; Whitney, none.

P. T. Colgan, Middlesboro, Ky., having twenty-five years' experience in the coal industries in eastern Kentucky and West Virginia, and J. L. Smith, Danville, with ten years' experience, with other engineers, made the report, Chairman Lewis said.

Coal-Mine Fatalities During March, 1924, by Causes and States

(Compiled by Bureau of Mines and Published by *Coal Age*)

State	Underground											Shaft				Surface				Total by States							
	Falls of roof (coal, rock, etc.).	Falls of face or pillar coal.	Mine cars and locomotives.	Gas explosions and burning gas.	Coal-dust explosions (including gas and dust combined).	Explosives. Lindon W. Bates

This internationally known hydraulic engineer, whose expert knowledge was manifested in the filling of the Kansas City Stockyards, the excavation of the Chicago Drainage Canal, the dredging of the Kaw, Mississippi, Scheldt, Volga and Danube rivers, the building of a harbor for Brisbane, Australia, and the raising above flood level of Galveston, Texas, died in Paris, April 22, from a stroke of paralysis. He was born at Marshfield, Vt., in 1858, and was a resident of Mount Vernon, N. Y. To mining men he is remembered as the inventor of colloidal fuel, a mixture of oil and pulverized coal, a dense and mobile fuel especially desirable for use on ships.

Wholesale Coal Convention Plans Nearly Ready

The Convention Committee of the American Wholesale Coal Association, of which J. W. Johns of Pittsburgh, Pa., is chairman, is rapidly concluding arrangements for the association's convention, to be held at the Greenbrier Hotel, at White Sulphur Springs, W. Va., June 3 and 4. The business sessions will be held in the morning of each day.

The committee announces the acceptance of invitations to address the convention by G. N. Snider, formerly freight traffic manager of the New York Central Lines and now general manager of sales of Dickson & Eddy, New York; Owen Meredith Fox, associate editor of *Black Diamond*, Chicago, and E. M. Platt, president of the Platt & Brahm Coal Co., Chicago.

West Kentucky Strike Drones Along Peacefully

Everything is quiet in the western Kentucky strike zone. The operators are making no effort to run their mines and there have been no clashes of any sort since the men laid down their tools on the night of April 15. Operators are not anxious to run in the face of the present market. A long drawn-out strike is in prospect. If there were any possibility of a stiff demand or better price for coal some operators might be willing to consider signing up. On the other hand a good demand at a better price probably would result in a number trying to run open shop on the 1917 wage scale.

Alberta Looks for Troubles In Its Coal Mining

Alberta coal reserves, systems of coal mining, methods of grading and of inspection, cost of production and the capitalization of companies and their profits are to be investigated by a royal commission appointed by the Government of the Province of Alberta. It was decided upon as a result of a motion by P. M. Christopher, M.L.A., the labor member from Rocky Mountain, which received the support of Premier Herbert Greenfield and the endorsement of the Legislature.

Premier Greenfield, speaking to the motion, said that transportation costs are Alberta's chief difficulty in the search for an adequate market for coal products, but it is not the only problem. There is the cost of production, which varies from approximately \$2.70 a ton, run of mine, at stripping steam coal mines west of Edmonton to \$6.50 for lump at the deep domestic mines at Lethbridge. At Drumheller the cost is \$4.50; at Edmonton, \$4, and at the Crows Nest Pass, \$4.25 a ton.

He said mine operators blame labor costs and the miners answer that because of intermittent employment they do not earn enough to keep their families in reasonable comfort. They argue that undue overhead costs and heavy capitalization of mining companies are important factors. The Premier thinks that something might be said for both points of view.

Discussing the capitalization of coal-mining companies in Alberta the Premier said that the total amount of securities issued by joint stock companies operating coal mines during the year 1921 was \$45,209,058. The production in 1923 was only 6,866,923 tons.

Heavy Loss in Abandoned Mines

Toward the end of 1919 it was estimated that \$18,795,755 had been invested in domestic mines in Alberta, of which \$4,378,500 was invested in mines since abandoned. At the same date it was estimated that \$18,315,000 had been invested in bituminous and anthracite mines, of which \$5,435,000 had been invested in mines since abandoned. Thus there was a total of \$9,813,500 sunk in abandoned mines.

In 1923 there were 362 mines operating in the province producing 6,866,923 tons, while in the Province of Nova Scotia 55 mines produced 6,500,000 tons. He maintained that high costs were due to some extent to the large number of small producing mines with the consequent multiplication of overhead and was of the opinion that this condition was the result of the ease with which leases of coal lands could be obtained under regulations of the Dominion Government.

Alberta had vast deposits of coal, it was said, but this was no excuse for wasteful methods of mining. He said that from 1905 to 1919 there had been blocked out for mining 102,603,927 tons, of which 54,379,081 tons had been extracted. Of the 48,226,846 tons still unextracted approximately 20 per cent would be recovered. This meant that 43,000,000 tons was lost.

"This matter of waste," he said, "has been engaging the attention of the

©Harris & Ewing

Senator Tasker L. Oddie

The Nevada Senator continues to advocate the creation of a department of mines and is at work on amendments to his bill which would apply to the coal industry. The new sections will provide for the appointment of advisory committees and the establishment of a bureau of coal economics.

Dominion Government, which is seriously considering the institution of a system of inspection of mines and mining methods in the interests of conservation. In Great Britain the proportion of coal salvaged is around 85 to 90 per cent. In Alberta the opinion of competent engineers is that the proportion salvaged is around 60 per cent all over the province."

Premier Greenfield closed with the statement that the Province of Alberta is negotiating with the Dominion for full control of her natural resources and that the Province has been endeavoring, in anticipation of the successful outcome of these negotiations, to obtain the fullest possible information regarding these resources.

To Study Mechanical Loading

A proposition is now before Director Bain which involves a study of mechanical loading by a fellowship research under the direction of the U. S. Bureau of Mines assisted by the Carnegie Institute of Technology, Pittsburgh, Pa. The Hillman Coal Co., Pittsburgh, offers to pay the way of a fellow to participate in the research; the Bureau is asked to furnish the services of an assistant mining engineer who will lead the work.

If the proposal receives the approval of the authorities in Washington—and most likely it will—the two men chosen for the work will go from mine to mine where mechanical loaders are used, observing performances and studying operating conditions. After an investigation of ten months, which will take them to all states mining coal, they will write a report of their findings and suggest methods and mine layouts for loading coal from the Pittsburgh seam with machihes.

More Than 100 Meet Death in Explosion In West Virginia Mine

Dispatch from Staff Correspondent

A violent explosion, in which, at the time this report was forwarded to *Coal Age*, 110 men were believed to have lost their lives, occurred at about 7:15 on the morning of April 28 in the Benwood mine of the Wheeling Steel Corporation, Benwood, W. Va., on the outskirts of Wheeling's industrial zone. The full force of men was at work, the man trip having entered the mine at 6:30 a.m.

The mine is a drift in the Pittsburgh No. 8 seam, from which about 900 tons are mined daily. It is very dry and is sprinkled daily in dry seasons. Few or no pumps are required in its operation. Open lights are used exclusively because the mine was never believed to be dangerous. The occasional pockets of gas found here, as also in most of the mines of the district, were never believed to make necessary any precaution other than ventilation and the regular inspection by firebosses.

The rescue crews are being hindered in their work by roof falls and deadly gases. About 1,400 ft. inside the drift mouth a big fall obstructs the entrance of rescuers. Consequently the base of operations is at the Browns Run air-shaft. This shaft, which was sunk to

facilitate ventilation, has been completed about five weeks. So far only thirty bodies have been recovered and little hope is entertained for the safety of the others. The ventilating fan was undamaged and is delivering 40,000 ft. of air per minute.

About three months ago a fireboss and two men were killed in this mine by the ignition of a pocket of gas. The cause of the explosion probably is, as usual, the ignition of an accumulation of gas and the extension of the explosion by coal dust. Federal Mine Bureau crews and those of the state and company are at the mine rendering assistance. Little progress has been made and consequently little is known regarding the condition of the workings.

Benwood mine adjoins several thousand acres of old abandoned workings. Probably much firedamp comes from these areas as a result of the destruction of stoppings and seals. While Pennsylvania state mine inspectors were in session in Pittsburgh discussing the advisability of rock dusting, rescue crews were at work in the Benwood mine searching for the bodies of men who had lost their lives in a coal-dust explosion.

North American Co.

Pays \$4,900,000 for

St. Bernard Mines

The North American Co., of New York closed an option April 26 on all the properties of the St. Bernard Mining Co. for \$4,900,000, according to advices from Madisonville, Ky. The new company will be merged with the West Kentucky Coal Co. under the latter name, and will be capitalized at \$15,000,000, of which \$6,000,000 is in preferred stock and \$9,000,000 common stock.

The new company will operate twenty-five mines, ten of them West Kentucky Coal Co. properties, with an annual output of 5,000,000 tons. The North American Co. controls the West Kentucky Coal Company, which is an organization with headquarters at Sturgis, where it operates coal mines as well as at Clay and Wheatcroft.

Negotiations for the consolidation have been in progress since January. C. F. Richardson, of Sturgis, president of the West Kentucky Coal Co., acted for the purchasers. The St. Bernard company was represented by F. D. Rash, Madisonville, president; J. R. Rash and M. K. Gordon, both of Madisonville, and Fustice A. Haile, of Nashville, Tenn.

An announcement from Madisonville was to the effect that there would be no change in the officers, personnel, policy or name of the St. Bernard Mining Co. It will operate, the announcement said, just as it has in the past and added that stock control is the only change in the ownership. Officials of the North

American Co. in New York City declined to make a statement.

Included in the deal are thirteen pit and strip plants, 44,000 acres of mineral rights, most of it timber land, all of the commissaries and tenant houses and the electric power plant at Earlington, which cost between \$740,000 and \$1,000,000.

Horrors! Bossy Competes With Coal Now!

The Rock Island R.R. has been mining its engine fuel from coal mines and oil wells mostly. But the other day it mined two tons from a dairy herd near Chicago and ran a five-car passenger train 20 miles on it. The fuel on the tender was dried and briquetted milk in white chunks fired from the tender by a hard-boiled fireman with a regular scoop into a regular firebox. And it made a fire so hot that the engine popped off most of the time—for the benefit of movie cameras and lots of spectators. The milk-fired run was engineered by the Chicago Health Department as a stunt to illustrate the fact that milk is such good fuel for human bodies that it will even run an engine. Since the famous milk run the Health Department has been trying to get Chicago to consume more good milk and the Rock Island has been trying to get the "goo" out of the flues of that engine.

House Committee Agrees to Defer Sec. 28 a Year

The House Committee on Merchant Marine recommended on April 26 that the operation of Sec. 28 of the Merchant Marine Act be deferred until May 1, 1925, and ordered a favorable report on the bill introduced April 12 by Representative Newton, of Minnesota. As originally drawn the bill would have postponed the effective date of the section until July 1 of next year.

Members of Congress believe that there is a chance for the Newton bill to be passed by June, and it is to be speeded. Mr. Newton said that he would ask for a special rule to give his measure preferential status. He will see Chairman Snell, of New York, chairman of the Rules Committee, this week.

Saturday's action was the result of protests from commercial interests in all sections of the country, who sent their representatives to go before members of Congress, the Interstate Commerce Commission and the Shipping Board. They declared that if Sec. 28 went into effect on May 20, as proposed under the order, it would demoralize the nation's industry, and in the terms of some of the witnesses, "make and unmake ports and industries."

The Interstate Commerce Commission decided, after a hearing, to postpone operation of Sec. 28 for thirty days, or until June 20, because the evidence showed that the railroads could not be ready by May 20 to put into effect the new preferential railroad rates on goods shipped for export on Shipping Board vessels, as proposed under Sec. 28.

Miners Oppose Concessions In Ohio Mines

A referendum of the miners in the southern Ohio field in the employ of operators connected with the Southern Ohio Coal Exchange, indicates, according to preliminary reports, that the miners are opposed to any concessions. When the scale in force during the past few years was affirmed for three years more as a result of the joint conference of operators and miners at conference at Jacksonville, Fla., it was understood that concessions in working rules might be made by which Ohio operators would get an advantage of 25c. to 50c. a ton, giving them much leeway in meeting competition of non-union mines in West Virginia and Kentucky. The exact status of the situation will not be known until the referendum vote is completed. The referendum vote is said to be very light.

A strike of a week's duration in the mines of the Pennsylvania Coal & Coke Corporation in Ehrenfeld, Cambria County, has been settled and the miners have returned to work. The trouble arose over the announced intention of the company of putting a night force to work in the mines. This the miners refused to sanction as not in keeping with the recently signed agreement. James Mark, vice-president of District No. 2, succeeded in adjusting the dispute.

Problems In Underground Management

Advice on Best Methods of Shooting Coal

Air Spaces Should Be Left to Spare the Roof and
Cushion the Blow on the Coal—Shearing
Sometimes Undesirable

IF ASKED what is the best explosive for coal mining I should be tempted to evade the question for want of detailed conditions, or else answer in a general way, that it is the explosive producing the results desired. The quantity and the size of coal produced is not dependent alone upon the kind of explosive. There are many other governing factors, such as the kind of coal, the depth of undercut, overcut or shear, the depth of the borehole, the quantity of explosive used and the tamping. Trials and tests will determine the best explosive and the best mining practice in any given mine.

GOOD TAMPING AFFORDS SAFETY

The only factor which is not variable is that of tamping. There is only one best method and that is to use stemming material which will pack solid, such as damp clay, and then tamp it tight right to the collar. Inflammable material such as "bug dust," paper or sawdust is banned. Good tamping not only provides safety in dusty and gassy mines, minimum of fumes and more efficiency from the explosive, but it also enables the powder to bring down a maximum percentage of the coal in desirable sizes.

Contributed by Atlas Powder Co.

The miner who uses a cheap explosive to save a few cents or who cuts fuse short to save a penny or two, or who to save a few minutes does not tamp a borehole is practicing a false economy. He saves about as much as the Hickville carpenter who spends an hour each day straightening bent nails to save buying new ones.

SLOW POWDER FOR BRITTLE COAL

In both bituminous and anthracite coal beds the quality of coal varies considerably. Some coals are hard and tough, and others are brittle. Even in the same mine the changing character of the coal sometimes necessitates different methods of operation. If a coal is easily broken, that is, brittle, a quick-acting explosive should not be used, as this will tend to shatter the coal and break it up into the smaller and less desirable sizes.

This is one of the reasons why many miners prefer blasting powder to dynamite; even to selecting a coarse-grained powder which is slightly slower in its action than a powder of finer grain. Large lumps of bituminous coal as a rule cannot be obtained with the quicker-acting explosives. The velocity of detonation for an explosive suitable for producing bituminous lump may run up to 8,000 or 9,000 feet per second, but for anthracite, explosives having higher velocities of detonation will work satisfactorily.

Undercutting, overcutting or shearing the coal helps materially in producing lump, and the extra face so reduces the resistance to breakage that much less explosive is required to bring down the same quantity of coal. Undercutting usually extends about 6 ft. deep from the face, but should be always a few inches deeper than the borehole. With proper undercutting, explosives are necessary to break

the coal into lumps small enough for the miner to handle.

Mining to obtain large lump may be overdone as when an easily broken coal is both undercut and sheared. A weak, slow-acting explosive in this case would be likely to produce a few large blocks which would have to be broken up later to loadable sizes. But this method of shooting down the coal almost unbroken and breaking it up after it has fallen does the least damage to a weak roof.

BREAKER SHOT THE HEAVIEST

The breaker shot, with undercutting, requires a heavier charge than subsequent shots. The first shot breaks against two free faces whereas subsequent shots are relieved by the extra face made by the breaker shot. If in a narrow bed the coal is sheared and the boreholes are placed midway between floor and roof, no extra free faces are obtained as each shot cleans out all the coal.

One of the Bureau of Mines requirements for a permissible explosive is that not over 1½ lb. (24 oz.) shall be used in any one charge. Tests in coal mines prove that this maximum charge suffices. A large number of tests show that the average loading is 14 oz. The depth of the borehole for coal mining runs from 4 to 6 ft. seldom exceeding the latter. The average depth of borehole over a series of tests was found to be 5 ft. 4 in. The average undercut with holes of this depth would be 6 ft.

The diameter of the borehole in general practice runs in sizes of 1½ in., 1½ in., 1½ in. and 2 in., the most popular diameter being 1½ in. With this size of hole, the average normal charge of 14 oz. (approximately two 1½ x 8 in. cartridges) will occupy when the cartridges are slit and well tamped, 13 in. of the bore hole. This leaves 4 ft. 3 in. of tamping, which sufficiently confines the charge.

Although blasting powder is fast, being replaced by permissibles, it is still used in large quantities, principally on account of its lower cost and the force of long practice among miners who are adept at rolling a paper shell and filling it with just the right quantity of blasting powder. Under the same conditions of blasting as with permissibles these cartridges of black powder would occupy from 22 to 34 in. of the borehole leaving only from 3 ft. 6 in. to 2 ft. 6 in. for stemming material, with a corresponding sacrifice of confinement. Laboratory tests made by the Bureau of Mines show that the more tamping used the greater the efficiency of the explosive, and they also show the superiority of moist clay over sand.

Miners are much more likely to over

Fig. 1.—The More Permissibles the Fewer the Fatalities

Chart shows how the death rate from explosives has decreased with increasing use of permissibles. The fatality rate, however, since 1914 fallen but little, though the use of permissibles has greatly increased, suggesting that other causes tended from 1903 to 1914 to reduce fatalities from explosives.

charge a borehole than undercharge it. They know that an insufficient charge especially of blasting powder, will blow out of the hole much as a bullet is fired from a gun, bringing down little coal, if any, and resulting in a waste of powder and time. Miners who have changed from blasting powder to permissibles almost invariably over charge the holes.

When a charge of over 24 oz. of any powder is used it ceases to be a "permissible" and outside of the fact that such overcharges become dangerous in gassy and dusty mines, they also have a tendency to weaken the roof. Overloading may develop fissures in a roof which are not immediately noticeable to the miner but which may later cause a fall of roof. If the coal will come down only by heavy charges then it is better to decrease the quantity of explosive in each hole and increase the number of holes in the face.

Permissible explosives being stronger and quicker than blasting powder, their action is more centralized at the bottom of the borehole. If this hole is drilled slanting upward or "pitching" and so that the bottom of the borehole comes just under the roof a dense explosive is liable to do more damage to the roof than a bulky one, because with the latter the force will be exerted over a greater length of borehole. Hence the user of permissibles will often find the bulky powders the more satisfactory.

AIR CUSHIONS ADVISABLE

In some coals it is found that the charge shatters excessively. This has led to the practice of leaving an air cushion around the powder. If permissibles are used the cartridges are placed in the borehole without being slit. The borehole, being of larger diameter than the cartridge, leaves the necessary air space. With blasting powder a space of a few inches is left at the end of the charge by inserting a wad of paper the desired distance from the end of the charge and then following with the stemming material. With the development of permissibles the use of an air cushion is becoming obsolete.

After all is said and done the best way to determine the proper explosive is to ask the service department of the explosive manufacturer to send an expert to demonstrate in the mine. In this way the best mining practice and the best explosive for that particular mine can readily be determined.

Fig. 1 shows graphically the trend of practice with respect to the use of permissibles, and the relation of such practice to coal-mine fatalities. It will be seen that since the introduction of permissibles and their constantly increasing use the number of fatalities in coal mines due to explosives has been constantly decreasing. Every year

Fig. 2—Pounds of Permissibles Used per Thousand Tons Mined

This chart is based on the yearly sales of permissibles and the entire production of coal. It must be remembered that it does not indicate in any way the quantity of coal broken down by any given quantity of permissible explosive.

there is a greater proportion of permissibles used as is shown graphically in Fig. 2.

Twists Props Loose Instead Of Pulling Them

When Henry Walker, deputy chief mine inspector of Great Britain, addressed a meeting of anthracite coal men at Scranton he said that in England the modern way of loosening and recovering props was by twisting them loose and then pulling them out.

Consequently the description of the "Wrester" prop-drawing device contained in the *Iron & Coal Trades Review* recently is of interest. Where the prop is set firmly it may resist pulling and another setting of the post puller may have to be made. When this is being done the man has to return to the place of danger, which has been rendered still more dangerous by the attempt to withdraw the prop.

At the Sneyd collieries, Burslem, sixty, "Wresters" are being used. As will be seen in Fig. 1 the device consists of the lever *A* which turns on the fulcrum pin *B*, within the jaw of the collar *C*,

Fig. 1—Twisting Collar and Lever

The teeth in the curved member *F* bite into the prop when the lever end *D* presses on it as a result of the pull on the link *G*. Nothing is said as to the possibility of pulling the prop where it is of irregular form such as is usual in this country where props are frequently made of split timber.

which it will be seen is adapted to more or less encircle the prop to be withdrawn. The shorter arm of the level *D* is provided with a curved surface and the extremity of the lever is provided with a link *G*. The curved member *F* which is provided with teeth on its inner surface bite into the prop and prevent the collar from slipping when the link *G* is pulled. It will be observed that there are no loose parts to be lost or to get out of place.

In Fig. 2 can be seen the way in which the Wrester is operated from a distance. A chain is fastened to the link *G* and connected to a prop puller which is attached to a post at a distance from the one being pulled. Only one man is needed to put the Wrester and the prop puller in place. This same man pulls the prop.

The device is manufactured by the Atlas Mining Outfit Co. Ltd. of Birmingham, England. It is made in two sizes, one to draw 3½ to 5½ props and the other for props of a diameter of 5, to 7 in.

Fig. 2—How the Prop Is Twisted and Withdrawn from a Distance

With this device there is a leverage that makes pulling easier. Several props can be withdrawn without changing the anchorage. In a demonstration one prop was drawn that had no cap piece but was bedded in the roof. The props are not injured, it is said by this novel method of freeing and drawing them.

Practical Pointers For Electrical And Mechanical Men

What Means Should Be Taken to Keep Mine Locomotives Equal to Their Work

Switch in Series Position, Haul in Parallel—Run on Resistance Points
No More than Necessary—False Flangers Cause Vibration
And Destroy Switches and Crossovers

A MINE locomotive is a rugged piece of equipment, but like all machinery, it requires care, repair and intelligent operation. The average man can operate a mine locomotive successfully if he uses common sense and follows the instructions of the electrician. The motorman should know the track on his run and should be well acquainted with the mine. He is usually directly under the supervision of the trip foreman or of the mine foreman, but he should endeavor to follow the instructions of the electrician in operating his locomotive.

He should keep it oiled and greased, unless there is someone employed to do that work, and I believe it is the best practice to have a man for this purpose if there are many motors. The motorman should report to the repairman any defect that he has observed in the operation of the motor. All motormen should know that track switching should be done with the reverse handle in the series position and haulage with the handle in the parallel position.

SAND SHOULD BE USED SPARINGLY

A locomotive should not be run on resistance points any more than necessary because such operation heats the grids and causes burnouts and grounds. The controller handle should be moved to a full point or notch every time it is moved because if stopped between the notches on the star wheel the segments and contact fingers will be burned. Sand should not be used any more than necessary. If used sparingly the locomotive will pull more cars. I have known of cases where a locomotive was insulated from the track by use of too much sand. This, however, does not happen often. When it does, it is a good idea to remove the trolley pole from the wire and make some kind of temporary connection with the rail before again attempting to move the locomotive.

Some coal companies require the motorman to blow the coal, dust and trash off the lids and frame of the locomotive at the end of each shift. This is good practice, but it seems that the motorman should not be the man required to do this work because it can be done to better advantage by a repairman.

A mine that has a number of locomo-

tives usually has a force of repairmen for the upkeep of the traction equipment. Also a shop either inside or outside the mine, according to the ideas of the management and whether it is a shaft or a drift mine. Of course repairs can be more effectively made by daylight, but that does not mean that equipment cannot be successfully repaired inside the mines. There is one difficulty, however, and that is, securing material. The shop should have a pit or pits that will accommodate two or more locomotives and still leave room for a man to work with some degree of comfort. The pit should be about 4 ft. deep, and as wide as the track.

SHOP SHOULD BE WELL EQUIPPED

One or more chain blocks capable of lifting one end of the locomotive and a 2-ton chain block is handy for moving trucks, complete motors and other heavy parts. Screw or ratchet jacks should also be provided. Bars, chisels, sledges and the wrenches furnished by the locomotive manufacturer should be available. Slings made of steel or hemp and bands for handling the armatures should be provided. One or two extension cords with lamp guards are almost an absolute necessity.

The repair shop should be equipped with a compressed-air line. It should be roomy as possible and well lighted. A substantially built bench with a vise is also essential. Drawers and shelves for small supplies and for the mechanics' individual tools should be provided. Large tool boxes should be placed for the heavy tools or they eventually will be lost. Over the bench should be placed a test light with long leads or a portable test light can be provided. These lights offer the simplest means of testing for grounds, shorts and opens in the wiring of the motors. An emery wheel comes in handy but is not absolutely necessary. Of course ideal conditions cannot be attained around a mine but the nearer they are approached the better the repair service, and the fewer the delays. A shop should have tracks entering at each end, but sometimes this is not possible.

When a locomotive comes to the shop or barn it should be cleaned by means of moderate air pressure. Then while

the lids are off, the motor should be given a thorough inspection; it should be scrutinized closely for loose nuts, bolts, or screws. The wiring should be examined where it leaves the conduit, where it enters the motors and controller cases to see if the bushings are worn or lost and to see whether the insulation on the wire is worn.

Any lost or worn bushings should be replaced, and the wire taped with insulating tape at worn places. If the strands of wire have been broken or burned by grounding it is advisable to either splice in a new piece or replace the whole length. Sometimes a wire which has been cut or burned can be repaired by a screw or soldered connector.

SEE THAT BRAKES ARE ADJUSTED

The brake mechanism should be carefully inspected to see if the shoes line with the treads and that the pins and keys are in place. If shoes are worn they should be adjusted or replaced. The brake screw should be run up tight and then loosened to see if the mechanism binds and to ascertain the available take up of the brake screw. The brake studs should be examined to see if they are loose. If the brakes do not set up tight they can be adjusted by the adjusting rod or turnbuckle.

The journal boxes should be packed with wool waste and the bearings filled with engine oil, unless some special oil is specified. Both should be of good quality. Black oil is not suitable for anything but track switches and guard rails. A journal should not be allowed to wear too thin as a jar will cause it either to split or break, depending upon its composition. If any of the lids are gone from the axle journal boxes they should be replaced.

The adjusting collar on the drive axle should be set so that the pinion has about $\frac{1}{8}$ in. endwise play to insure a smooth, even wear of pinion and gear teeth. The pressed-on type of gear gives less trouble, but many good split gears are on the market. A false-flanged wheel should not be allowed on a locomotive as it not only causes excessive vibration to the equipment, but damages switches and crossovers. Flat spots on the treads should be ground down, whether caused by sliding or soft spots in the metal.

The motor suspension should be examined, gear cases aligned and tightened and any holes patched. The grease cups on armature bearings should be filled with a good quality grease. Practically all mine equipment now has either roller or ball bearings, which do not give as much trouble as sleeve bearings. All nuts and bolts on the motor case should be kept tight

and fastened with cotter keys. The motor cases are of two types, box and split frame. Both have their advantages and disadvantages, but of the two the split frame is easier for armature or field changing, more especially when a defective field is in the top half of the motor frame. The sand levers and valves should be kept in good condition. On straight track the sand spouts should line with the wheels. I have heard many persons theorize on the subject claiming that the sand rigging working on one side and not on the other was the direct cause of axles being twisted in two.

The trolley base should swivel freely, and on straight track the wheel should align with the wire. If there are no abnormal conditions the trolley should not arc on straight track. The terminal screws should be tight and the pole cable in good condition. Insulating straps of rubber or leather are a good means for holding the cable tightly against the pole. I have seen tape used for this purpose but believe it is a wasteful practice.

BACKPOLING IS DANGEROUS

Poles should be of a soft wood which will split easily, because nearly all motormen occasionally backpole and a hard, unyielding pole is more dangerous than one of soft wood. Backpoling is a dangerous practice and should not be allowed. I have put on as many as three poles in one night, all broken by motormen who persisted in that practice. The cable socket should be carefully lubricated and examined to see that its contacts are not burned or pitted.

I know of one case where a pole caught in a frog and was jerked out of the pole socket. Instead of the cable pulling out of its socket it pulled the socket from its fastenings and jerked the motorman from his seat with the result that a trip of thirty cars passed over his body.

A locomotive repairman has a heavy responsibility. The controller which is always the brain of any electrical installation, when applied to mine locomotives is as simple as it can be made and still perform the necessary operations. It is substantially built of heavy contacts and arc protectors.

The more modern controllers have arcing tips that do not cost as much as the whole finger or segment. These can be renewed with a great saving in cost. Any accumulation of copper should be removed from the arc shields. The controller should be blown out with a moderate air pressure or a hand bellows and the contacts greased with commercial vaseline. Too much vaseline does more harm than good. The star wheel and the shaft bearings of both operating and reverse cylinders should be oiled occasionally.

The mine-locomotive motor is a product of years of study by the best mechanical and electrical engineers, and it is as well adapted to the mine conditions as any piece of machinery. Motors operated in the mines labor under disadvantages greater than in any other industry. Water holes, dripings from the roof, coal dust with carbon are present in nearly every

Ashley Planes Lift Coal at Low Cost

This is the longest railroad plane in the anthracite field and perhaps the longest in the world. A series of three planes nearly three miles long elevate coal cars over 1,000 ft. high from the valley near Wilkes-Barre, Pa., to the top of the mountain. The cost to elevate a ton of coal on these planes is 4c. With the best operating conditions it would cost 20c. to do this same work by means of a locomotive running over long winding tracks. More cars can be hauled up the planes in thirty minutes than the largest locomotive can pull on the tracks in twelve hours. The cables used on the planes are 2½ in. in diameter. These cables last from ten to seventeen months.

mine. The motors have few ventilation ducts because if they did water would get to the windings. Of course this is offset to a great extent by ventilating fans on the armature shaft.

INSPECT MOTORS CAREFULLY

Locomotive motors are not where they can be easily inspected and in some cases they operate almost continuously. In many mines the return circuit from the locomotives is bad and this causes the motors to heat abnormally. Motors should be carefully inspected for rough commutator, worn brushes, burned pigtails or shunts, high bars and open circuits. The brushes should be free in the holders and the holders tight on the rigging. The tension should not be too loose, a pressure of about 4 to 6 lb. per sq. in. being good practice.

If a motor shows abnormal heating it should be thoroughly tested for grounds and defective fields. Imperfect bonding will cause the motors to heat. In a split frame motor the lead coming from the lower half should be carefully inspected to see that it does not get caught between the two halves of the frame and become damaged or grounded.

Last but not least the resistance banks should be examined for open circuits, grounds and burned or broken grids. All parts should be kept tight as loose grids cause burning which is the chief cause of grounds. If grids are loose they tend to chafe the mica-insulating tubes. Running the motors on the resistance points of the controller causes abnormal heating of the grids. Headlights must be kept in good condition at all times and the frame bolts, bumper bolts, etc., should be tightened at least once a week according to the service.

An Easy Method of Making Sectionalizing Taps

The small insulator and cross-arm fixture shown in the illustration demonstrates a convenient way to use standard strain insulators for taking off taps to sectionalizing switches on any kind of power, telephone, or signal circuit.

It is often convenient in such lines to have disconnecting switches that will sectionalize any troubles that may arise. When electricians are required to go over a line to locate trouble, it often is necessary for them to open up the circuits here and there and test in both directions for grounds and short circuits. The arrangement shown in the illustration is simple and consists of two standard porcelain insulators and a bracket which is attached to the cross-arm by a ⅜-in. bolt.

Strain Insulator Attachment
Sectionalizes Line

Two wet-ware porcelain insulators and a bracket provide an easy method for taking off taps for the sectionalizing of switches or circuit breakers.

Discussion

Railroad Rates Set for All Tidewater Coal Not Subject to Section 28

So far as coal is concerned the one matter of interest in the order of the Interstate Commerce Commission putting Section 28 of the Merchant Marine Act in force is whether this order will prevent tidewater transshipment bituminous coal rates from being applied on bituminous coal exported in ships of foreign register sailing from North Atlantic ports.

It is very doubtful whether the order will have this effect on export bituminous coal, because the tidewater transshipment tariff rates in no way differentiate between coastwise or export, cargo or bunker, coal and are not predicated in any way upon the rates for water haulage beyond the railroad terminals.

The rates were established in the first place to permit the movement of water-borne bituminous coal into the New England markets, and the use of

them on coal which has been exported has been entirely incidental and due solely to the fact that the rates have been published without any restrictions as to their use. They have not been based "in whole or in part" on the fact that any bituminous coal which may move on them is to be transported beyond the railroad in foreign water-borne commerce.

From 1896 to 1924, the total bituminous coal transshipped at tidewater at the North Atlantic ports grew steadily from eight million to twenty-eight million gross tons, and the New England tonnage grew from four million to twelve million. Meanwhile the export coal which totalled only one-half million in 1896 amounted to only four and one-half million in 1924.

be at any time the cause of the death of a few or a thousand men. When a few men are killed where hundreds are employed it is not due as a rule to any precautions taken by the management.

The lesson to be learned from the recent explosions are first that the use of open lights in a mine requiring firebosses is a dangerous practice and that fencing and posting signs will not save us from disastrous explosions when working around falls and where there is a squeeze. Particularly is this true where the squeeze becomes so dangerous that fireboss' examinations cannot be made to warn the workmen of the true situation.

Many Peculiar Mine Names Near Portage

Answering the challenge in the issue of *Coal Age* of Dec. 27, p. 968, I present the following odd names for coal-mining plants: Starting at the foot of Martin's Branch of the Pennsylvania R.R. Co., running out of Portage, Pa., we have the following collection of ordinary and extraordinary names, given in the order of their occurrence along the branch: "Miller Shaft," "Red Bird," "Jail Bird," "Big Apple," "Fiddler's Green," "Robin's Nest" (now idle), "White Elephant," "Puritan Shaft," "Pearces," "Wild Cat," "Penker." Then come the two Budapest mines, one known as "Buda" and the other "Pest"; "New Drift." "PeeWee's Nest," "Last Chance," "White Weazel" and "Rojohn."

They tell the story hereabout of a salesman who was hunting for a mine and asked a man on the tippie where the mine belonging to a certain company was. The man replied that he did not know. But the fact was the salesman was then standing on the tippie of the company he named and the mine was the one for which he was looking. A little thing like a company's proper name does not worry the men here, just so payday comes regularly.

JEROME C. WHITE,
The Penker Coal Mining Co.

Portage, Pa.

Rock-Dust for Barriers from Cement Plants

On page 231 of *Coal Age* for Feb. 14, 1924, I note an editorial under the title "A New Use of Trade Associations," referring to the possibility of a number of mines combining together in order to obtain a sufficient quantity of ground shale or limestone for use in dust barriers in the mine.

It may interest you to know that some years ago while endeavoring to introduce the use of rock-dust barriers in Oklahoma mines, I found that the local portland cement plant was grinding shale and limestone which could be used for such barriers. From the investigations which I made at that time I feel quite sure that any portland-cement plant can furnish the material for rock-dust barriers.

J. J. RUTLEDGE,
Chief Mining Engineer,
State of Maryland.

Lots Should Be Drawn for Working Places

I read with interest the article by Alfred Jones, Wheeling, W. Va., in your issue of Jan. 3 entitled "Apportioning Working Places to Miners by Lot." Not only has this custom been in existence in the Durham mines for years, but it has regulated the distribution of working places throughout the whole of Australia, and New Zealand. I spent nearly seven years in Australia as a mine manager, and the system works works satisfactorily.

The practice is as follows: Eight days before the cavil is to be drawn the pitboss numbers all the places. The day before the cavil the pitboss and two miners appointed by the men inspect all places to be allotted. When the day arrives the same two men, with their checkweighman, the pitboss, mine manager and one of the office clerks, meet in the office to draw the cavil. All the men select their partners and hand their names to the checkweighman, who hands them over to the mine manager.

The names are all written off in pairs and put into a hat with little balls all numbered to correspond to the numbers of the places in the mine. After shaking, the hat is held above the heads of those present and drawing starts. One of the miners draws a ball and notes the number, say 36. The pitboss then draws a paper with the names on it, say J. Jones and R. Stewart. These names are put down to place No. 36, and so on. The names and the ball No. 36 are put aside and drawing continues.

When the drawing is finished the clerk has the completed list with the

names and numbers, and this is posted at the office where the men can see the numbers of the places they have drawn, and in the morning they know just where to move their tools, so that little time is lost in moving.

The miners clean off all their places the day of the cavil. In the place thus selected the miner works for three months when another cavil is held. The foreman cannot take the room away from him. If the foreman stops the place to get rid of the man it must stand till the next general cavil. He may make a change, however, with the consent of the miners themselves, the pit committee and the manager. If there are any places finished during the cavil, the men displaced must be given other places. For this reason there are always a few rooms kept empty. Should two or three places finish the same day, the miners must cavil for the places to be awarded them.

JAMES GRAY.

Newcastle, Wash.

Banish the Hazardous Open- Flame Lamp

At a large number of mines in this country where a little gas is found and open lights are used, firebosses are employed as a precaution, who examine the mine before the men enter and while they are at work. This plan is recognized as safe in some of our leading coal-producing states. The mystery of it all is that it has proved inadequate in so many instances and yet continues to be recognized as the best we can do. Recent explosions have proved to us again and again that a little gas now and then is a real menace and may

Production And the Market

Depression in Coal Markets Near End; Tendency Is Steadier, Undertone Hopeful

While there has been no pronounced recovery from the monotonous condition of dullness that has been prevalent in the bituminous coal markets it is probable that the bottom of the valley of depression has been reached. The Lake navigation season was ushered in last week with the arrival of three cargoes at the head of the lakes and several others are said to be on their way, but the movement is far from being under full headway. Operation at mines throughout the Central Competitive Field are at an exceedingly low ebb, production in the southern Ohio field being down to 10 per cent of capacity.

The consensus of sentiment seems to be that the trade is so flat on its back that the only direction in which it can look is upward. Though larger consumers for the most part still are averse to buying except for immediate requirements, contracts are being signed up here and there by railroads and industrials. The curtailment of output is having a steadying tendency, there being less glutting of markets with its inevitable accompaniment of distress coal. A number of producers and jobbers argue that many large users who have been living off their stockpiles will have eaten so deeply into their reserves soon that they will be forced into the market again.

Government to Encourage Early Buying

The Department of Commerce contemplates instituting in the near future a campaign to start domestic consumers of coal laying in stocks at this time. In announcing the plan last week the department stated that it is proposed to wait until domestic consumers have used up the remainder of their winter supplies and then show them that with the present favorable condition of transportation and the low price of coal, now is the propitious time to lay in supplies. Later on

industrial consumers will be urged to place their orders for fuel, the scheme being designed to have one buying movement follow the other, in order to avoid traffic congestion and the possibility of undue effect on the market that might ensue if both classes of consumers began a concerted buying movement at the same time. The fact that the railroads had a surplus of 180,000 coal cars on April 14 is convincing proof that they are unusually well prepared right now for putting such a scheme into successful operation. All that is necessary to initiate the movement is some orders.

Coal Age Index of spot bituminous-coal prices registered a slight rebound during the last week, the April 28 figure being 171 and the corresponding price \$2.07. This compares with \$2.04 on April 21 and \$2.71 a year ago.

Activity in the export field was less marked during the last week; nevertheless total coal shipments from Baltimore for foreign ports during the first twenty-four days of April were greater than for the full month of either January, February or March. Italy was the largest purchaser, with France second. Porto Rico has been a steady buyer in small quantities.

After a prolonged period of decline the production of bituminous coal recovered slightly during the week ended April 19 when, according to the Geological Survey, the output totaled 6,945,000 net tons, compared with 6,834,000 tons during the preceding week. Anthracite output was 1,623,000 net tons, a decline of 233,000 tons from the previous week.

Demand for anthracite is somewhat stronger, which with the lessened output has tended to make independent prices firmer on domestic sizes. This is attributed in part to end-of-the-month buying in anticipation of a possible advance in prices, as the cuts at the beginning of the month were announced as for April only.

(a) Revised from last report. (b) Subject to revision. (c) Minus one day's production to equalize number of days in the two years.

Midwest at a Standstill

A practical standstill has been reached in the Midwest. The time of the year is about right for such a standstill, and the market conditions are at their worst for the time being. Stocks on hand in consumers' piles are disappearing, however, for most big buyers are confident coal will not be high at any time this year and are disposing of their storage fuel as swiftly as possible so as to enter the market about midsummer. A few small contracts are written day by day, but no heavy contracting is wound up.

Indiana and Illinois mines are working at low ebb—probably the lowest in history. The movement of large sizes is practically stopped and all mines have a certain number of "no bills" in those sizes, even though the mines may have been down for several weeks. Screenings continue in fair demand and light supply but without price changes from last week. Pocahontas is the only Eastern coal reaching the Midwest just now and that is coming in small volume at a mine run price declining from last week's spread of \$2@\$.25. The May price may run under \$2.

In southern Illinois fields a little railroad tonnage is moving and the strip mines are working fairly well. This seems to be principally on railroad coal. The mines continue to shut down until further advised and there is con-

siderable dissatisfaction among the miners, who are hopeful that the west Kentucky strikers will win out and thereby give southern Illinois a better chance in the open market.

In the Mt. Olive district there is no change from last week, excepting in the matter of screenings, which are quoted at \$2. In the Standard district it is hard to move anything, with the exception of screenings and small nut.

It is reported that the Rock Island contract was let at \$1.78 for Standard mine run. The mines fortunate enough to run are getting one to two days a week and this is principally on railroad coal.

St. Louis domestic business is at a pause. The dealers are buying a little anthracite and that seems to be all. They all have a little coal in the yards that they are trying to clean up. Wagonload steam is easy and continues to ease off. Country domestic business is dead but there is some steam business, principally on screenings and small sizes.

West Kentucky Sells Some

As a result of the coal strike in the larger section of the western Kentucky field the mines in the unaffected sections including non-union mines, independents, strips and union mines which have a year's contract still in effect, are getting a very fair business. The West Kentucky Coal Co.,

Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines

	1924 April 28	1924 April 21	1923 April 14	1923 April 30
Index	171	169	172	224
Weighted average price....	\$2.07	\$2.04	\$2.08	\$2.71

This diagram shows the relative, not the actual prices, on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913-1918," published by the Geological Survey and the War Industries Board.

Sturgis, non-union, is able to load out a big tonnage, and is handling a good deal of coal just now. The strippers and other operating companies are enjoying the removal of competition from the mines that are down. Production of operating mines has been quite fair.

Movement is principally on mine run and screenings, there being light demand for prepared sizes, which is resulting in relatively small supplies of screenings being produced and a relatively high price. Screenings and mine run are both selling at \$1.60@1.75. Nut coal is \$2@2.25, and all other sizes, \$2.25@2.50, including egg, lump and 6-in. block.

Louisville jobbers and producers of coal report that demand is generally quiet. The strike in western Kentucky has resulted in better movement of eastern Kentucky screenings into Louisville, there being a difference in price sufficient to absorb the 43 to 53c. higher freight rate from eastern Kentucky. Eastern Kentucky screenings are selling at \$1@1.25, as against \$1.60@1.75 for western Kentucky.

Little Action in Northwest

Navigation opened on Tuesday of last week with three cargoes received at Duluth-Superior. The Northwestern Fuel Co. got the first cargo at its Superior (Wis.) dock and the Inland Fuel Co. received two cargoes about half an hour later. Several more cargoes are reported on the way from the Sault, and it is thought that before the week is out all docks will have received coal.

Great rejoicing is evident among dock men at the recent decision of the Interstate Commerce Commission raising the hard-coal rate from mines to Twin Cities \$1.05 on net and \$1.16 on gross tons. This brings the freight back to

\$8.50 again, which will allow the docks to compete not only in Twin Cities but also in North Dakota and similar states. The new decision may see a resumption in anthracite activity, which will mean that the usual tonnage will be brought up this year.

Prices are the same in anthracite as last reported, and the list in bituminous is holding, but several docks are reported to be cutting 25c. a ton lump Youghiogheny, Hocking and splint for spot delivery. The docks are not contracting ahead at present prices, as they assert that coal costs them \$5 laid down here, without local dock charges. On the other hand, buyers are in the market for nothing but spot coal, and are not interested in contracts. They look for another drop. Consequently everything is lovely. A little more coal is moving to public-utility plants and open-pit iron mines, because of the absolute failure of water supply. The situation is unprecedented.

With new coal being unloaded onto fairly well filled docks and with almost a total lack of demand, the coal situation at Milwaukee at present is exceedingly dull and unpromising. The only feature of the market worth noting is the tightness of soft-coal screenings. April coal arrivals by lake thus far aggregate 10,000 tons of anthracite and 22,975 tons of soft coal. A number of additional cargoes are on the way.

West Is Quiet Too

The Kansas City market remains quiet. Little progress has been made in the joint conference of scale committees of operators and United Mine Workers. Such Kansas coal as is available, most of it the product of mines independent of the Southwestern Interstate Coal Operators' Association, is quoted at \$4.50 for lump, \$4 for nut, \$3.25 for mine run and \$2.50 for slack. Henryetta (Okla.) coal is \$5.50, \$3.75, \$3.50, and \$2.50.

The coal market in Colorado remains practically the same as last week inasmuch as the mines worked on an average of twenty-three hours per mine for the week. A number of unbilled loads of domestic sizes were reported on track last week. Operators report 35 per cent of the working time lost last week on account of "no market." Prices are unchanged.

In Utah the coal business is referred to by operators and retailers as "Rotten!" Mines are working around two days a week. Industries are buying very little and the domestic consumption has fallen off as a result of the ideal spring weather which prevails. The slack situation is easier due to a falling off in demand. The chief coal railroad in the state has written the operators using its line begging them not to load any more "no bills." Mine prices have taken another drop, but retail prices remain firm. The new mine prices are: Lump, \$3.50; domestic lump, \$3; stove, \$2.75; egg, \$2.50; nut, \$2.25; screen slack, \$2@2.25; slack, \$1.50.

Cincinnati Discerns Better Feeling

A much better feeling is evident below the surface in the Cincinnati market. Consigned and distressed coal has virtually been wiped off the slate. Practically all of the low-priced slack has been wiped out, run of mine quotations are firmer and even the makers of sized coal have caught the fever. Smokeless is even stronger than the others. Specialized coals are quoted as follows: Block, \$2.75@3.50; egg, \$2@2.75.

A slightly improved feeling is developing in the Columbus market. While prices have not advanced, the tone is stronger and operators and wholesalers believe that the worst of the slump is over. Some contracting of commercial tonnage is reported, but mostly on a tentative price basis. Railroad contracts have been attracting attention and several large agreements have been closed, it is reported, with the price of Hocking mine-run around \$2. There is not nearly as much distress coal on the market. Retailers are cleaning up stocks and in doing so are often cutting prices. Retail prices are generally irregular. Pocahontas and some of the West Virginia grades are showing slightly more strength. Some inquiries have been made as to lake tonnage but no contracts of consequences have been entered into. Conditions are not favorable for an early opening of the lake trade. Uncertainty as to rates and other conditions are holding up contracts. Little tonnage from the Hocking Valley field is expected to be moved to the head of the lakes during the present season.

Production in the Southern Ohio field is settling down to

around 10 per cent or less of capacity. In the other Ohio fields a better output is reported, but it shows a falling off from the figures of previous years.

Operators and jobbers say that aside from inquiries for slack, there is no significant change in the lethargy which has held the Cleveland market in its grip since the latter part of March. There are reports of additional mines closing, and one large company operating seven or eight mines in the eastern Ohio field has closed all its mines except one. The smaller mines are practically all closed. Aside from some shipping by operators who have dock interests at the head of the Lakes, the shipping of coal from the mines to the lower Lake docks has not yet begun.

The market at Pittsburgh has sagged even further. There is practically no demand at all and prices in general are unchanged, save for a slight advance in slack. Line consumption is decreasing, the outlook being distinctly poor in the steel trade.

The situation at Buffalo does not change much. Though bituminous output is declining fast, it has not yet reached a level low enough to affect prices.

There is little activity in the soft coal market at Toronto. Pennsylvania smokeless is selling at \$7.30, and steam lump at \$7.40, delivered. Slack is rather scarce, and brings \$6.40. The market for anthracite still continues firm, many people buying with a view to laying in a supply for next season.

New England Notes Firmer Tendency

In New England there are indications of firmer prices on the smokeless coals from West Virginia. Accumulations at Hampton Roads have steadily diminished until there is only a moderate tonnage on wheels in excess of orders in hand. Deliveries on contract are being made in reasonably good volume, and on the whole there is a slightly better tone to the market.

Buying, however, shows no improvement. The textile, shoe and machinery trades are still suffering from dull business, with prospects not favorable for the next few months. In the cloth trade there is depression due to competition from English mills, and large numbers of plants here are operating at a loss. Reserve stocks of coal are as large as early in the year, the "bargains" of the past few weeks having induced consumers to replace actual consumption, in many instances.

For distribution inland from Boston, Providence, and Portland there has also been an appreciable lift in spot prices. Quotations of \$5.35@5.50 per gross ton on cars have now lapsed, and the asking figure has advanced to \$5.75@6, with sales reported at \$5.65@5.85.

At Norfolk and Newport News the spot range has slowly advanced from \$4.25 to \$4.40 and \$4.50 per gross ton, f.o.b. vessel for No. 1 Navy Standard Pocahontas and New River. No. 2 coals have advanced similarly from \$4.10 to \$4.25.

Meager Movement to Seaboard Markets

The lessened movement of coal to the New York market has served to maintain prices on about last week's level, for demand is still slack. Not much coal is being forced on the market unless the producer is compelled to get rid of it. Line demand continues dull but there was a trifle more activity at this tidewater. Loaded boats are gradually disappearing. Contractors continue to hold off for the most part and go into the open market to replenish their reserves.

Business in the Philadelphia market has slumped a little more. Conditions at the mines do not improve and there is

more idleness now than actual work. Market prices manage to hold firm, but even at the present level there is not much stability, and there is no telling what price the consumer might get on a good sized block of coal. Of course a large share of the business is on lots of one to five cars and on these the prices have not changed.

In the face of the cut in soft-coal production there has been no material stiffening of the market at Baltimore. At present demand for both steam and gas coals is at a minimum and prices continue on the same low level maintained for the past few weeks.

General dullness continues to prevail throughout West Virginia, with such mines as are able to operate at all limited to about two days a week. Prices are so low that in some sections of the state at least producers are making no effort to operate unless they have contracts.

Although there has been little or no improvement in actual business in the Birmingham market, conditions in some respects are more healthy. There is little surplus coal, which has had a tendency to stabilize prices and remove under-cost selling to a great extent. Spot business is still light in volume and contracting is rather slow, though renewals are negotiated in most cases with the expiration of old agreements.

Anthracite Business Shows Firmness

Prices for independent domestic coals at New York are slightly firmer, demand having increased. Some of this increased activity was attributed to buying in anticipation of a 10c. advance by the producers. Stove coal continues to be the most popular size, though egg is in good demand in the New York market, call for this size showing much more action than a couple of weeks back. Chestnut size does not move as freely, but is in good demand. The past week has been a busy one for retail dealers. There was a little less activity in the steam coal market due to more seasonable weather, but not sufficient to show any surplus in any of the sizes.

Unusually cool April weather at Philadelphia has served to keep up a good current demand and business in a retail way is really good for this time of year. The Easter vacation of the miners has also had a strong effect on market conditions, and with the exception of nut coal, and the steam coal sizes, the operators are having very little trouble to move the output. The anthracite situation in Baltimore has resolved itself to a fairly settled basis. While some individual decisions may be made as to selling prices at retail, pending a more or less settled policy resulting from meetings of the coal exchange, it seems likely that the trade as a whole will continue the present schedule of prices at retail up until July 1.

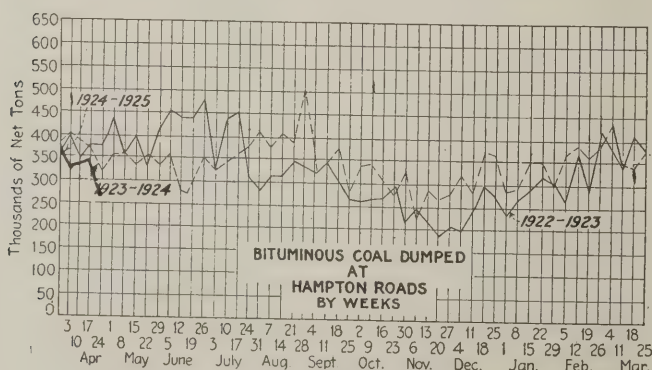

Coke Market Dormant

The coke market continues practically stagnant, there being scarcely a ripple from sales or even inquiries. Output of beehive coke during the week ended April 19 was 254,000 net tons, according to the Geological Survey, compared with 265,000 tons during the previous week.

Foreign Market And Export News

British Prices Weaken with Waning of Strike Menace; Output Lower

Recovery from the usual holiday lull in the British coal market is gradual. With the waning of the strike menace prices are weaker in the South Wales trade and demand is slack.

The market at Newcastle also is weaker, and prices are declining. Present activity is entirely confined to filling orders booked some weeks ago.

A substantial increase in the German coal output, especially from the occupied district, in the last few months serves to aggravate the situation for British coal interests. The Ruhr is the key to the coal trade position today, the latter say, and the more coal produced by Germany the less will the leading Continental markets require from Great Britain.

A cable dispatch to *Coal Age* states that British coal mines produced 5,843,000 tons of coal during the week ended April 12, according to provisional official reports. This was a decline of 9,000 tons from the output of the preceding week.

The court of inquiry appointed to investigate wages and living conditions of coal miners has begun work. As the old contract expired April 17, the miners are working on a day-to-day arrangement pending the outcome of the inquiry.

Demand Keeps Pace with Output In French Markets

Demand for coal in the French markets is keeping pace with offerings, both in industrial and domestic fuels. Output is sold one month in advance; disposals are few and new business exceptional. The British market has been stronger due to the menace of a strike. Prices show a tendency to advance, as the demand is very strong.

With the continuance of cold weather, activity in the sale of household coal is holding above the level usually recorded at this time of the year. Owing to the rise of salaries and transport costs, dealers in the Paris area

have decided not to alter their quotations during the month of April. It is probable, however, that summer prices will be applied in May, which will show a cut in quotations.

Output of coke during April is averaging about 19,400 tons daily, which is far in excess of that prevailing before the occupation. Owing to the recovery of the franc, the price for indemnity coke has been placed at 145.25 fr. on trucks frontier, Sierck, for the first two weeks of the month. To this will be added 0.50 fr. per ton, representing the expenses of administration of the O.R.C.A.

The rolling stock situation has improved slightly, but it is still far from normal.

Trade Slumps at Hampton Roads; Prices Rise as Supplies Fall

Business at Hampton Roads has slowed down, although prices are stiffening as result of reduced supplies at tidewater. Mines serving the port report shutdowns, due to overproduction, and the supply of coal on hand is dwindling.

Hampton Roads piers are running on part time, with indications that April will be one of the duller months of the year. Foreign movement is fairly brisk, coastwise trade is dull and bunker business fair.

News Items From Field and Trade

ALABAMA

A. A. Fendley has been elected president and Ed. H. Rauwald secretary of the **Blount County Mining Co.**, of Oneonta, which was recently incorporated and has 300 acres of coal land under development.

ARKANSAS

Production of coal in the mines at Branch during the week of April 12 was the **highest of any week** since the local field was opened. A total of 886 narrow-gage cars was loaded into 72 standard gage cars. The record shows that 1923 was the best year for Branch since the railroad was built, the shipments totaling 1731 standard cars of coal.

COLORADO

The **Cliente Coal Co.** has been incorporated in Walesburg, with a capital stock of \$50,000, by R. L. Snodgrass, S. M. Thompson and G. McNally.

During the month of March Colorado produced 894,262 tons of coal. This was an increase of 17,724 tons as compared with the same month last year. A total of 12,044 men was employed in and about the mines.

ILLINOIS

An official of the Union Colliery Co., of St. Louis, Mo., states that **but one man suffered a broken leg in the falling cage accident at the Kathleen mine** of that company April 10 at Dowell. A number of men were given attention at the Marshall Browning Hospital at DuQuoin, but the broken leg was the most serious injury.

The **Pike County Collieries Co.**, 1141 North Vermilion Street, Danville, has been incorporated with capital of \$62,500 to own, lease and operate coal mines. The incorporators are H. C. Adams, Thomas J. Hawkins and Charles F. Shannon.

Holly Stover, Inc., the Stover Coal Co., the Stover Elkhorn Coal Co. and the Star Coal & Coke Co. have removed their offices from the McCormick Building to suites 910-912, Straus Building, 310 South Michigan Ave., Chicago.

A number of important improvements are soon to be made at Zeigler No. 1 and Zeigler No. 2 mines, in Franklin County, of the Bell & Zoller Coal Co., of Chicago. At old No. 1 mine three steel stacks, one of which blew down early in April, and four boilers, all of which were nearly twenty

years old, are to be replaced. A big concrete stack is to replace the steel ones. The main shaft will be retimbered. At No. 2 mine a crusher is to be installed and a new docking table for egg coal with conveyors to and from it are to be bought. This will necessitate an addition to the steel tipple.

INDIANA

All bids for providing the state's coal for next year have been rejected by the Indiana State Purchasing Committee. Fred B. Robinson, secretary of the committee, said the committee regarded the prices as excessive. The committee will ask for new bids at once. It is expected that the new proposals will be opened some time late in May. The lowest bid submitted for mine run coal, Fourth Vein, was \$2, while Fourth Vein strip coal was bid at \$1.98. Bids on Fifth Vein coal ranged from \$1.75 to \$2.25 for mine run. A number of bids submitted for eastern Kentucky, West Virginia and Illinois coal were not given serious consideration because of prohibitive freight rates.

The **Otter Creek Coal Co.**, of Brazil, has been petitioned into bankruptcy by the First National Bank, Kattman & Tillet, and the Citizens Telephone Co., all of Brazil. The petition says the indebtedness totals \$16,975.

KANSAS

The **Kansas first-aid and mine-rescue meet**, which was to have been held in Arma, May 17, **has been postponed** because mine idleness has taken so many men out of the field. If a contract for the Southwest is made soon enough to permit training, the state meet will be held a short time before the national meet at Huntington, W. Va., in September.

Ouster proceedings against Leon Besson, state mine inspector of Kansas, were instituted in the state Supreme Court April 21 by Attorney General C. B. Griffith. The Attorney General contends Besson is not qualified for the position because he has not complied with the state law requiring the state mine inspector to pass an examination before the state mining examining board.

KENTUCKY

John C. Smith, superintendent of the **Black Mountain Mining Co.**, of Harlan, on April 16 **denied reports** carried in the press to the effect that the company was planning to start up its mines

non-union, as a result of a walkout of 500 men on April 1, when a reduction in wages was refused by the workers. Press reports were to the effect that trouble was brewing, and that troops would be in readiness. Smith replied to this by stating that the company had no intention of running unless it came to some sort of an agreement with the union.

Through the efforts of coal interests, headed by a western Kentucky coal operator in the last session of the Legislature, a bill was enacted whereby an armory commission was created, which is now obtaining armory connections for state troops in various sections of the field. This will result in more numerous enlistments, greater interest and better drilled troops, which will have more equipment and know how to use it. It will also mean troops available for labor and other disturbances on short notice. Contracts for housing have been completed at Carlisle, Covington, Winchester, Williamsburg, Poorfork, and are pending at Barbourville, Harlan and London, while arrangements will be made at Whitesburg, Hazard, Jackson, Beattyville, Booneville, Richmond, Monticello, Springfield, Hopkinsville, Mayfield, Bowling Green, Russellville and Livermore, which will give better protection in a number of isolated districts.

On April 18 Judge John L. Srout, referee in bankruptcy at Bowling Green, named M. M. Ennis, of Bowling Green, as receiver for the **Drakesboro Coal Co.**, of Drakesboro, which had previously filed a voluntary petition in bankruptcy in the Western District U. S. Court, at Louisville, listing assets of \$11,080 and liabilities of \$13,105.07. Assets include a twenty-three year lease on 300 acres of coal land, with free use of rail connection to the Louisville & Nashville R.R., tipple, mine equipment, etc. Ennis will serve pending election of a trustee, after a settlement with the striking coal miners of Western Kentucky.

It is reported from Middlesboro that **mines in that section are operating on the 1917 scale or below**, and that the Southern Railway Co. has increased coal purchases by 40 per cent, which is resulting in about two days a week added to running time over a dull period.

It was reported from Harlan on April 18 that **J. O. Carey**, superintendent of the **Intermountain Coal & Lumber Co.**, at Putney, was instantly killed by a sawlog when a log train on which he was riding was wrecked.

The Hombre Coal Co., at Coolidge, in Perry County, has been purchased by Henry Dabb and coal interests of Norton, Va., resulting in changing of the name of the company to the Coolidge Coal Co., with main offices at Norton.

NEW YORK

The Virginia Iron, Coal & Coke Co., reports for the quarter ended March 31, 1924, a net income of \$5,792 after charges, against \$75,371 in the previous quarter and \$243,559 in the first quarter of 1923. The net income of \$5,792 for the first quarter of 1924 is equal to 11c. a share on the \$5,000,000 preferred stock against \$75,371, or 12c. a share, on \$10,000,000 in common for the previous quarter and net income of \$243,559, or \$1.81 a share, on common in the first quarter of 1923.

The Board of Directors of the Pennsylvania Coal & Coke Corporation on April 22 declared the regular dividend of \$1 per share of the accumulated earnings and surplus of the company, payable on May 10, 1924, to stockholders of record at the close of business on May 5, 1924. The company reports for the month of March a deficit of \$11,774 after ordinary taxes, depreciation and depletion and other charges, but before federal taxes. This compares with a surplus of \$122,444 reported for the corresponding month of 1923. For the first quarter of this year the surplus was \$1,001, against \$394,217 in the first quarter of 1923.

OHIO

Representatives of some fifty mines in the Kanawha fields of West Virginia met at the Sinton Hotel in Cincinnati on April 24 at the call of D. C. Kennedy, secretary of the Kanawha Operators Association, to consider the juggling of freight rates by the Interstate Commerce Commission at the behest of union operators to the north of the Ohio River. Efforts have been made in Washington to raise the West Virginia and Kentucky lake and rail rates and lower those from the Ohio mines. Determined opposition to such a plan was voiced by those present and legal as well as association representation before the commission was authorized. No further action was taken regarding the shutdown of the Kanawha mines, which would indicate that the operators intend to sit still on this question until some definite move urges them to action.

Papers have been filed with the Secretary of State, authorizing the increase in capital stock of the Doanville Coal Co., of Nelsonville, from \$10,000 to \$30,000. A. D. Knight is president and George E. Johnson, secretary.

Sunday Creek Mine No. 21, located in the Sugar Creek field, has been closed until market conditions improve, throwing out of employment about 600 miners

The 1,500,000-ton contract of the New York Central Lines, including all of the western divisions of that system, is attracting considerable attention among Columbus producers and

distributors. While all of the contract has not been closed it is reported that the George M. Jones Co. received 600,000 and the Sunday Creek Coal Co. 400,000 tons. The price was \$2 for mine run. Others are bidding on the tonnage, but the official award will not be made for a week.

Charles J. Albasin, commissioner of the Pittsburgh Vein Operators' Association, reports that 64 mines in the eastern Ohio field have been closed down because of lack of demand, between 7,000 and 8,000 miners having been thrown out of employment as a result. A portion of the miners are working part time, however. Production in the district is at the lowest point in years, according to reports received from all sections of the producing field.

G. C. Weitzell, president of the New Pittsburgh Coal Co., Columbus, a subsidiary of the Pittsburgh Coal Co., has returned from a three months' vacation trip spent in California and the Hawaiian Islands.

Sealed proposals will be received May 9 by the Board of Education of Columbus for 7,000 tons, more or less, of bituminous run of mine; 8,000 tons, more or less, bituminous lump; 2,000 tons, more or less bituminous nut, pea and slack, to be delivered to the various schools.

Sealed proposals were received April 16 by the City Board of Purchase of Columbus and contract awarded to the Sunday Creek Coal Co. on a bid of \$1.45 f.o.b. mines for coal as follows: 5,000 tons of Hocking nut, pea and slack for the Municipal Light plant; 3,500 tons Hocking nut, pea and slack for the Water Works Department and 2,000 tons Hocking nut, pea and slack for the Garbage Disposal Plant.

The Cedar Heights Clay & Coal Co., Oak Hill, has been chartered with a capital of \$25,000 to mine and sell coal. Incorporators are James G. Morgan, Margaret J. Morgan, Anna Marie Kern, Roscoe Kern, Effie C. Howell and Alonzo E. Howell.

PENNSYLVANIA

The H. C. Frick Coke Co. has closed down ten plants in the Connellsville district and most of the others are running four or five days per week. The Oliver & Snyder Steel Co. coke plants are operating about 20 per cent. The Monessen Coal & Coke Co., a subsidiary of the Pittsburgh Steel Co., is operating about 50 per cent. The Buckeye Coal Co., a subsidiary of the Youngstown Sheet & Tube Co., has closed down its Brier Hill coal plant, and during the shutdown is changing from its steam plant to power purchased from the West Penn Power Co. The Republic Iron & Steel coal and coke operations are operating about 40 per cent. The Hillman Coal & Coke Co. is operating about 60 per cent. W. J. Rainey, Inc., continue to operate about full time.

Conferences with mine inspectors and colliery superintendents upon the subject of safety are to be conducted throughout the summer by Joseph J. Walsh, Secretary of Mines.

The monthly accident report of the Bureau of Workmen's Compensation of the State Department of Labor and Industry shows that during March there were 94 fatal accidents in coal mines of the state.

J. M. Sloan, secretary of the Anthracite Forest Protective Association, and fire wardens in the Hazleton district have been kept busy with a series of forest fires. Collieries and coal banks in several sections were menaced. A large gang of men extinguished a raging fire near Grape Run, which was rapidly approaching the refuse and coal banks at the Spring Mountain operations of the Lehigh Valley Coal Co. Brush fires to the east and south of Eckley were numerous. Several occurred near Highland. A serious fire burned at Evergreen Valley for several days.

Indications that the strike at the Lehigh Valley Coal & Navigation Co. in the Panther Creek Valley will complete its third week were manifest when Thomas Kennedy, district president of the United Mine Workers, announced that suggestions for a settlement by J. B. Warriner, general manager of the company, had been rejected. Several conferences were held between officials of the union and company heads.

An active campaign waged by United Mine Workers officials of District No. 1 for David Fowler for the Republican nomination for Congressman for Lackawanna County was unsuccessful. With every district heard from Fowler lost to Laurence H. Watres by nearly 5,000 votes. Fowler obtained the Democratic nomination, but being a Republican since he entered politics, little hope is held out for favorable support from the Democratic party leaders. Mr. Fowler is an international organizer of the United Mine Workers.

On April 21 Judge Thompson, of the U. S. District Court at Philadelphia, appointed William O'Malley temporary receiver for the White Ash Coal Co., Minersville, and for the Marshfield Coal Co., of Tremont. Bills in equity were filed by Thomas F. O'Malley, a creditor of both companies. The two companies are owned and managed by the same interests. June 18 was fixed by the court for a hearing to make the receivership permanent.

Thomas Elliott, of South Brownsville, president of the Lilly Coal & Coke Co., of West Brownsville, Pa., returned home last week from a trip of several months to Europe for rest and recreation.

The Oak Hill coal breaker and separating plant of the Pine Hill Coal Co., Minersville, was destroyed by fire recently, causing a loss of about \$100,000, including equipment.

Stream pollution due to wastes from coke-oven plants in the western part of Pennsylvania has virtually disappeared, according to Dr. Charles H. Miner, Secretary of Health and a member of the State Sanitary Waters Board. All of the large coke plants have installed apparatus, at the suggestion of the State Health Department, to arrest the flow of trade wastes into the Ohio,

Allegheny and Monongahela rivers. "As a result of this action upon the part of the large coke manufacturers in the western part of the state," said Dr. Miner, "Pennsylvania is far ahead of both West Virginia and Ohio in the matter of elimination of trade wastes from the waters of the state." The states of Ohio, West Virginia and New York are now endeavoring to co-operate with Pennsylvania in the drafting of a program for uniform anti-pollution regulations on interstate streams, such as the Ohio and the Delaware rivers.

VIRGINIA

At a meeting of the board of directors of the Pocahontas Coal & Coke Co. held April 22 A. C. Needles was elected president of the company, effective May 1, 1924, in succession to N. D. Maher, retired.

WEST VIRGINIA

In future trials of those implicated in the Logan "armed march" cases of 1921, the state will be represented by Harold A. Ritz, just designated by Governor Morgan to serve in that capacity. In the cases already tried, counsel for the defense have always laid stress on the charge that the state was not represented in the prosecution but that outside attorneys were employed by members of coal operators' associations. Judge Ritz formerly was on the West Virginia Supreme Court bench, retiring a year or so ago to engage in private practice in Charleston.

The Maryland-New River Coal Co., of Philadelphia, has a newly completed tippie, erected at a cost of \$100,000, at its mines on Keeney Creek. It is one of the largest in the New River field, its equipment including screening facilities, loading boom, etc. The new structure is of wood and will take the place of two old tipples at the Rothwell Smokeless mines, the output of both workings being dumped over the new Tipple. The saving in labor costs, it is estimated, will amount to \$100 per day.

The Buffalo Valley Collieries Co. has just been launched with a view to operating in the Brooke County section of the northern Panhandle of West Virginia; capital, \$150,000; headquarters, Wellsburg. Chiefly interested in the new concern are Daniel Reamer, Fred Cooper, George S. Shrader, John S. Duvall, of Monessen, Pa., and W. W. Luce, of Vernon.

The Logan Eagle Collieries Co. has been authorized to change its form of capitalization from 5,000 shares of preferred stock at \$100 and 20,000 shares of no par value stock to 7,500 shares of common stock of a par value of \$100.

The Betty Ann Collieries Co., of Putnam, will soon install shaker screens in its mine at that place. Other improvements will be made to the property. The exclusive sales contract for the product of this company has been taken by the Wheeler Coal & Coke Co., of Columbus, Ohio. William Jones is manager of the Betty Ann Collieries Co.

A total of 3,424,144 net tons of smokeless coal was produced during February, as against 3,282,518 net tons during February, 1923. The Pocahontas field produced 1,637,925 net tons as against 983,625 tons in February, 1923. New River production amounted to 719,712 tons as against 551,513 tons in February, 1923. Winding Gulf produced 642,767 tons as against 471,060 tons in February, 1923. Tug River produced 423,740 tons, as against 276,320 tons in February, 1923. Of the total smokeless produced, the Norfolk & Western handled 2,061,665 tons, the Chesapeake & Ohio 753,025 tons and the Virginian 609,454. Total coal shipments in February by the Chesapeake & Ohio were 3,322,596 tons, as compared with 3,041,365 by the Norfolk & Western and 694,216 by the Virginian.

Only five new coal companies were organized in West Virginia in March, a much smaller number than usual, due in large measure to the depressed state of the coal market. The five companies organized—all resident—had an aggregate capitalization of \$410,000. Included in the list were: Thomas & Wilson Coal Co., of Buckhannon, which will operate a lease on Cabin Creek, \$50,000; Big Otter Collieries Co., of Wheeling, with a capital of \$30,000; Banfi Coal Co., of Follansbee, with a capital stock of \$25,000; Kentucky Coal & Land Co., of Wheeling, with a capital of \$25,000; Nonsuch Pocahontas Coal Co., of Iaeger, with a capital stock of \$10,000.

The Deaker Hill Coal Mining Co., operating near Kingwood, in Preston County, has been placed in the hands of a receiver on an order of the Circuit Court of Preston County. W. P. Walker of Akron, Ohio, and James W. Flynn, of Kingwood, were appointed receivers by Judge Hughes.

The Interstate Coal & Coke Co. has filed a certificate of dissolution. The Mack Coal Co. has changed its form of capitalization from \$150,000 to 1,000 shares of preferred stock at \$100 and to 1,500 shares of no par value.

The Wilbur Fuel Co. has increased its authorized capital stock from \$500,000 to \$1,000,000.

WASHINGTON, D. C.

The U. S. Supreme Court has granted a motion to advance the case of *Davis, Director General, vs. the Corona Coal Co.* Argument has been set for May 5. In this case the Director General of Railroads sued the coal company for damages to a wharf owned by a railroad under his jurisdiction at New Orleans when a tug of the coal company collided with it. The Louisiana courts held that the suit had not been brought within a year, which was the time limit for such actions under Louisiana law. The Director General appealed on the ground that he was not subject to the state law in such suits.

The Civil Service Commission announces examinations for junior engineers, to be held throughout the country May 9. The optional subjects include the following divisions of

engineers: Aeronautical, agricultural, ceramic, chemical, civil (general), electrical, electro-chemical, fisheries, hydraulic, materials, highway, industrial, irrigation and drainage, mechanical, mining, petroleum, radio and structural. The Bureau of Mines will name several junior mining engineers and has one opening at present.

The Roslyn Coal & Coke Co., of Tacoma, has been incorporated by A. F. Plant and George H. Reed for \$50,000.

CANADA

The British Columbia Electric Ry. has let contracts exceeding \$400,000 for improvements to its gas plants at Vancouver and Victoria. Among the improvements to the Vancouver plant is a coke briquetting plant of a capacity of 25 tons per day.

Pattison & Bowns, Inc., of New York City, has acquired an interest in the St. Lawrence Importing & Distributing Co., Ltd., of Canada. This company has been for some time past engaged in the sale of anthracite and bituminous coal in Canada, with offices in the Royal Bank Building, in Toronto, Ontario. George S. McSweeney, formerly connected with the Century Coal Co., of Montreal, has become affiliated with the St. Lawrence Company as general manager and will have his headquarters in Montreal. Pattison & Bowns, Inc., is a subsidiary of the United States Distributing Corporation.

More than 100,000 tons of coal has been contracted for in Newfoundland for delivery this summer from the Dominion Coal Co. Of this amount between 50,000 and 60,000 tons will be taken by the Newfoundland government to be used by its boats, railways and other services. The balance has been sold to local dealers at St. Johns.

Keen competition has set in at Montreal between the dealers handling Welsh and Scotch anthracite and those selling the American product. The price of American anthracite has been reduced from \$17 a ton to \$15.25. The price of coke has been lowered from \$14 to \$12.50 per ton due to competition from Nova Scotia coke.

W. Donaldson, lessee of the Donaldson-Tennant coal mine near Lethbridge, where a strike of miners is in progress, has subleased his mine to the miners. It is the first effort since the strike started, April 1, to operate any of the mines in the district. Officers of the United Mine Workers have ordered heavy picketing of the mine and proclaim the workers as strike breakers.

Practically all the United Mine Workers' locals in Pictou County, Nova Scotia, have passed strongly worded resolution urging the government to increase the duty on American coal to \$2 per ton. Pictou County collieries are working only two to four days a week, and this probably will continue until after the opening of navigation. The local unions also urge on the Dominion Government a reduction in freight rates on the Canadian National Ry., so that Nova Scotia coal may enter the Quebec and Ontario markets.

Traffic News

Northwest Hard-Coal Rate Favors the Docks

The decision of the Interstate Commerce Commission on the matter of withdrawing the joint freight rate on hard coal all-rail from Buffalo to the Twin Cities was exceedingly quick. The decision was something of a compromise in that it refused to allow the rate to become the sum of the locals, and further agreed with the objectors that the long-haul rate need not be based upon the distance wholly. But two-thirds of the proposed increase of \$1.66 was allowed, or \$1.16, which will become effective with the filing of new tariffs and the customary period of notice. This will mean, unless there is some further interference, that the all-rail rate will be increased by \$1.16 about May 29. Under the old rates, all-rail hard coal had an advantage over the laid-down dock coal price of about 35c. The increase will give a handicap of 81c.

The dock concerns insist that the change will make no difference in their prices. The independent retail concerns which fought the new rates insist that it gives the dock trade a practical monopoly of the hard-coal business, as the handicap forces the independents to buy from them and also prevents bringing all-rail coal through in an emergency. They predict that it is only a matter of time when the dock price will be increased by \$1.16, as a result of doing away with the all-rail competition.

Dismiss Complaint Against Pennsy

The complaint of the Lackawanna Steel Company against coal and ore rates from points in Pennsylvania to Buffalo, N. Y., was dismissed April 25 by the Interstate Commerce Commission. The complaint was filed against the Pennsylvania R.R. and charged that rates on coal and coke from Reynoldsville, Pittsburgh and Connellsville, Pa., to iron and steel manufacturers at Buffalo were unreasonable and that rates on ores shipped from lower Lake Erie ports to competing interior iron and steel manufacturers were unreasonably low.

Two Roads Pay; One Escapes

In the case of the Midland Coal Co. against the Midland Valley R.R., the Interstate Commerce Commission has been called upon to prorate the amount of reparation due the coal company on certain shipments from Williams, Okla., to Kansas City. The coal moved over the Midland Valley, the Missouri, Oklahoma & Gulf and the Frisco. In a previous decision the commission awarded reparation with interest against the three carriers. The Missouri, Oklahoma & Gulf was sold under foreclosure. The purchaser, the Kansas, Oklahoma & Gulf, bought the line with the condition that all claims against the property must be pre-

sented within ninety days after the sale. As the amount of reparations owed by the one carrier could not be collected, the examiner has found the amounts chargeable to the two other carriers and recommends that they be instructed to make such payments to the coal company.

Finds Indiana Rates Reasonable

Rates on bituminous coal in carloads from the Brazil-Clinton and Linton-Sullivan mine groups in Indiana to various Indiana points are not unreasonable, in the opinion of Interstate Commerce Commission Examiner Carter. In his report to the commission he recommends that the complaint against these rates be dismissed. The complaint was filed by a number of retail coal dealers in Indiana.

Coming Meetings

Chamber of Commerce of the United States. Twelfth annual meeting at Cleveland, Ohio, May 6-8. Secretary, D. A. Skinner, Mills Bldg., Washington, D. C.

National Exposition of Coal Mining Equipment and Machinery of the American Mining Congress, May 12-17, Cincinnati, in conjunction with the annual meeting of the National Coal Association.

West Virginia Coal Association. Annual meeting May 13-17, Cincinnati, Ohio. Secretary, W. H. Cunningham, First National Bank Building, Huntington, W. Va.

National Coal Association. Annual meeting, May 14-16, Cincinnati, Ohio. Executive Secretary, H. L. Gandy, Southern Building, Washington, D. C.

Mine Inspectors Institute of America. Annual meeting, Sinton Hotel, Cincinnati, Ohio, May 14-16. Secretary, Martin Bolt, State House, Springfield.

Retail Coal Dealers Association of Texas. Nineteenth annual convention, May 20 and 21, Vernon, Texas. Secretary, C. R. Goldman, Dallas, Texas.

Pennsylvania Retail Coal Merchants Association. Twentieth annual meeting and exposition, Commercial Museum, 34th and Spruce Sts., Philadelphia, Pa., May 22-23. Secretary, W. M. Bertolet, Reading, Pa.

International Railway Fuel Association. Sixteenth annual convention, May 26-29, Chicago, Ill. Secretary-Treasurer, J. B. Hutchinson, 600 Michigan Ave., Chicago, Ill.

The American Society of Mechanical Engineers. Spring meeting May 26-29, Cleveland, Ohio. Secretary, Calvin W. Rice, 29 West 39th St., New York City.

American Wholesale Coal Association. Annual convention, White Sulphur Springs, W. Va., June 3-4. Secretary, G. H. Merryweather, Chicago Temple Bldg., Chicago, Ill.

West Virginia Coal Mining Institute. Annual meeting June 3 and 4, Elkins, W. Va. Secretary, R. E. Sherwood, Box 1026, Charleston, W. Va.

The National Foreign Trade Convention. June 4-6, Boston, Mass. Secretary, O. K. Davis, 1 Hanover Square, New York City.

National Retail Coal Merchants' Association. Annual meeting, Hotel Virginian, Bluefield, W. Va., June 4-6. Secretary, Walter D. Rogers, Transportation Building, Washington, D. C.

Southwestern Interstate Coal Operators Association. Annual meeting June 10, Kansas City, Mo. General Commissioner, W. L. A. Johnson, Keith & Perry Bldg., Kansas City, Mo.

Illinois & Wisconsin Retail Coal Dealers Association. Annual meeting, June 10-12, Delavan, Wis. Secretary, I. L. Runyan, Great Northern Bldg., Chicago, Ill.

Illinois Mining Institute. Annual meeting, June 12-14 from St. Louis via boat down the river. Secretary, Martin Bolt, Springfield, Ill.

American Society for Testing Materials. Annual meeting, Chalfonte Hotel, Atlantic City, N. J., June 23-27. Secretary, Edgar Marburg, University of Pennsylvania, Philadelphia, Pa.

New Equipment

Small Light-and-Power Plant

A small kerosene or natural-gas light-and-power plant for use without a battery has been developed by the Westinghouse Electric & Manufacturing Co. for service wherever the current can be turned directly into the line. The absence of the battery adds greatly to the ruggedness and portability of the plant, and it is particularly well suited for direct service or for auxiliary or standby service to supplement existing generating equipment in such places as mines and quarries, construction camps, pumping stations, barges, boats and dredges.

The plant has a capacity of 1,500 watts at 110 volts. It consists of a gasoline engine and an electric generator built into a single compact unit. The engine is air-cooled, which makes it possible to install it in unheated places, economical in oil and fuel consumption, ruggedly constructed, and operates at a slow speed. It has a capacity of sixty 25-watt lamps or about 1½ hp.

A distinctive feature of the plant is the ease with which it can be operated. There are no complicated adjustments or operations necessary to start or stop it, and no other attention is necessary while it is running except to keep the fuel and oil tanks supplied. The single-cylinder, four-cycle engine has a 3½-in. bore and 5-in. stroke. A fan in the flywheel draws air into the cylinder dome and over the cylinder fins, assuring cool operation under all conditions.

The engine is lubricated by a splash-feed system which supplies the proper

Small Generating Unit Which Requires No Battery

The engine operates on kerosene or natural gas. Fuel is supplied by a Venturi mixing valve. The generator will supply energy to a 1½-hp. load.

quantity of oil to the moving parts at all times regardless of the depth in the crankcase. This is accomplished by an oil-carrying gear that dips into the oil in the crankcase and carries it to a pan keeping the oil in this pan at a constant level. A simple Venturi mixing valve is used instead of the usual complicated carburetor. Fuel is drawn by suction to this valve from the 6-gal. tank built into the base of the unit. A simple mechanical governor controls the speed of the engine by regulating both the fuel and the air. The complete unit conforms to the requirements of the Fire Underwriters.

Vibration Prevents Screen From Gumming

A vibrating screen designed to separate fine particles of byproducts, coke, coal and limestone has recently been placed on the market by the Link-Belt Co., Chicago, Ill. Provision has been made to provide uniform vibration over the entire screening box. The screen is vibrated by the action of an unbalanced pulley which is supported on the screening frame and rotated at high speed. The unbalanced pulley may be adjusted to impart to the main screen box rapid vibrations of the proper intensity and direction to screen many different kinds of materials. The pulley is provided with a bushing and is lubricated automatically under forced-feed. The screen box is arranged for one, two, or three screen decks, depending upon whether two, three, or four sizes of material are to be produced. The screen cloth is mounted on a movable frame carried within the box, each provided with means for stretching the cloth. The box is clamped rigidly to the hollow stationary shaft carrying the vibrator pulley. The vibrations are imparted directly to the box and screen cloth.

The screen box with feed hopper and discharge chute is suspended from two hollow cross shafts, the ends of which are carried on flat spiral springs on the supporting structure.

Screen Sifts Fine Materials

Vibrations are produced by the action of an unbalanced pulley rotated at high speed. It is claimed that all parts of the screen surface are uniformly vibrated.

Arcwall Coal-Cutting Machine Approved

The latest addition to the list of permissible coal cutting machines, approved by the U. S. Bureau of Mines, is a Jeffrey direct-current arcwall coal-cutting machine. Two approvals were issued by the Bureau covering the 250-volt and 500-volt design.

The complete machine consists of a self-propelled truck having a turret mounted on its front end which carries the cutter bar and the motor driving the cutter chain. The motor which drives the cutter chain also supplies power for turning the turret.

A second motor having a controller and resistance serves to propel the truck and raise and lower the turret. The cable reel, fuse and switch compartment are mounted on the rear of the truck. If desired, a headlight mounted on the turret, is furnished, but only on a 250-volt machine. The wiring between compartments is run in flexible armored conduit, except that to the turret which is run in armored hose.

The various compartments containing electrical parts were tested in explosive mixtures of Pittsburgh natural gas and air, and all passed successfully the required examination.

Square-End Pipe Cutters

Three new cutters, suitable for use on pipes ranging in size from 2½ in. to 12 in. have just been placed on the market by the Borden Co., of Warren, Ohio, manufacturers of the Beaver pipe cutters and dies. Though the same knife construction and automatic feed used on smaller sized cutters are provided on these latest types, the driving pinion remains stationary, rotating the cutting knives by means of an inclosed worm gear.

The adjustment to various sized pipes is made quickly—the same knives cut all sizes—and as no feeding is required while cutting, the tool works rapidly. It is claimed that the knives

Cutters for Large Pipes

It is easy to cut almost any size pipe with this new cutter. The ratchet handle permits the use of the cutter in the most confined places.

and other parts will not break. These new cutters may be operated in any position on the pipe, either by hand or mechanical power.

The cutters are made of high-speed steel and malleable iron. The device is easily portable and readily placed on pipes of greatly varying size.

Four-Speed Hoist

Here is a hoist with a four-speed gear reduction particularly suitable for very long hauls on steep inclines. It is provided with a long, wide drum equipped with deep flanges. The speed reductions are accomplished by means of a transmission gear unit very similar to that used on automobiles. The design of the hoist is such that it can be operated from an alternating or direct-current constant speed motor. A large heavy brake suitable for holding any load up to the full capacity of the machine is provided on each hoist. The operation of the brake is made very efficient and yet easy by means of a long lever-type brake arm. The complete unit is the product of the Silent Hoist Co., of Brooklyn, N. Y., and is suitable for rope pulls up to 12,000 lb.

Utility Hoist Specially Suitable for Locating Mine or Railroad Cars

Speed control can be obtained through a four-speed gear shift, thus this hoist may be used to move heavy loads at slow speeds, or light loads at high speeds. The whole unit is mounted on a common I-beam base and may easily be shifted about the mine yard for moving timber or cars.

NEW YORK, MAY 8, 1924

Number 19

Why?

MANY coal companies are at their wit's end to keep from bankruptcy at present prices. Others neighboring to these are producing coal from similar seams at prices 50c., or more, lower. Some say the difference is nearer \$1. There are two reasons—one is that the distressed companies are too poor to buy the necessary machinery and the other is that they are too conservative to fall into line with progress. Either reason is a heavy indictment of the coal industry.

A number of companies will attempt this year to get among the low-cost producers. If they will not or cannot they would do well to commit suicide according to forms provided by law. They merely prolong their agony by refusing to use the means of rejuvenation which other companies have adopted.

Too Much Mine

TOO many mines is hardly worse than "too much mine." Most of the slackness in supervision, most of the idleness of day hands, most of the aimlessness in operation, most of the irregularity of mine-car service is chargeable, and indeed is frequently charged, to the hopelessness of co-ordinating the activities of a big mine with only a small output over which to spread the supervisory costs. Fortunately every mechanical advance makes concentration of operation more possible. Let every effort be made to work intensively, to shorten up roadways, to reduce the length of airways, to decrease the mileage of track, of trolley wires, of timbered roads and other expensive items.

It is better to save the costs of track, power, trolley and pipe lines, pumps and timber and put this money into mining, loading and conveying machinery. Men have been described as "land poor" and in a similar sense coal companies may be said to be "mine poor" and "entry poor." A rambling mine like a rambling manorial mansion is costly to maintain. Close up your many storied, multi-corridorred residence and live in a cottage with but one floor and few rooms. With adequate facilities you will get just as much coal from the smaller mine.

Can the Union Fields Compete?

FORTUNATELY for the union fields of the bituminous industry, the non-union fields cannot supply the whole market any more than the big anthracite concerns can supply the entire demand for hard coal. As a result of this inability of the large anthracite firms to provide at times all the anthracite needed, the independents are able frequently to sell at a higher price than is set by the larger anthracite firms. The anthracite business is, therefore, in a degree non-competitive.

In a similar way the union fields will not in a certain sense have to compete with the non-union, for the latter fields cannot supply all the coal needed. There are too many restricting conditions. The railroads in most non-union regions are already grievously overloaded. New and better equipment will help, especially electrification, but, nevertheless, the railroads will be unable to afford the necessary service. Then again, men will be scarce at the coal mines. The restrictions of immigration lay a heavy hand on advancing coal territory and press far less heavily on coal fields that are declining. Mines in union territory are usually so circumstanced that they can draw from other industries if they need the men, whereas those in non-union fields can do so only by colonization, and the men colonized who cannot revisit their friends and who find the scenery different and urban conditions lacking are liable to be discontented. Furthermore, freight rates which favor non-union fields in certain directions hamper them in others, often not in proportion to the distance to the market, but enough to give the union in its own natural field, an advantage partly counterbalancing the greater cost of production.

So there will still be some hope, not much perhaps, for union fields; and those mines that distance others in efficient low-cost production may get such a generous measure of the business available to union mines as to remove them from the list of the impoverished and complaining. In fact, the bad roof in some non-union mines will make complete modernization slow and difficult, and the advance of the industry may make it questionable whether they, despite their low wage scales, can compete in a market dominated by machine-loaded coal, union and non-union.

New Problems in Merchandising

A FEW years ago the temperatures in furnaces were low and coal was sold on the number of British thermal units. Even that quantity was seldom determined. Then suddenly we heard about the fusing temperatures of ash. It is not so long ago that the president of a bituminous mining institute and a leading operating man, learned for the first time that the ash of the coal he was producing and marketing had an unusually high fusing point. He had never realized before that he had in that fact a favoring condition. He doubtless realizes it now.

At first the reactions to this unknown variable were somewhat strange and even today they are not marked by any proper comprehension. Companies producing coal with varying fusing points desired to operate their mines incognito, so to speak, so that they could supply their customers from any mine they preferred. They did not agree to send the coal from any specific mine or any given bed. Where all the mines of any company

produced coal from the same bed the effect was not particularly detrimental. A little more or a little less impurity is not so distressing as a greater or lesser fusibility of the ash.

Where, however, this latter quality is important by reason of the type of stokers employed and the customary over-rating of the boilers it was suicidal to ship coal from a mine the ash of which had a low fusing temperature to a customer who had a high-temperature furnace and a stoker ill-suited for handling clinker.

It is still customary, we are informed, in the anthracite region for large companies to sell their steam sizes without agreement to ship from any one mine or any certain groups of mines. It is still the plan to mix, in the breakers, coal from different seams, mines and culm banks. Perhaps these practices are justified, but the small company with a favorable fusing point and but one mine has sometimes a considerable advantage. It gets to be known as the producer of steam sizes not likely to give trouble when the fires are forced.

The problem of the mixing of coals and the selling of the output from all the mines of a company without discrimination is one that is worthy of consideration. It may pay to say that Buckwheat No. 3 is just that and nothing more or it may pay to say it comes from seams or mines that produce a coal having an ash which does not fuse at a low temperature. This introduces complications in producing, cleaning, storing and selling, and complications in these departments in themselves are not desirable. They militate against economy in producing and handling but perhaps they might help in marketing.

This suggestion is given in the hope that it may receive consideration. The validity of the proposal depends on the character of the product of the mine. Some companies may be able to produce and sell their output without any discrimination other than that of size, but others may do well to segregate the product and place it where it will do the best work.

Larger Coal

MINERS, now that their compensation is based on the quantity of mine-run coal produced, shoot it without mercy or judgment, with the result that much of it is merely stoker fuel. Some operators are trying to instruct and coax their men into adopting better methods, but the effort, though commendable, is not productive of good results. Even the present low prices and poor market do not make the miners realize that on the quality of their product depends the ability of their employer to provide them with work.

The article by Charles H. Thompson in the "Problems in Underground Management" section of this issue calls attention to one way in which the problem may be met, not so much by intention as incidentally. In a truly mechanically operated mine the operations at the face fall into the hands of three classes of operatives—the mining-machine men, the men who drill and shoot down the coal and the machine loaders.

It is not feasible to give any two of these jobs to the same crew. Consequently, those who drill and shoot holes for mechanical loading will be so few that it will be possible to select and train these men to such a degree that large coal will be obtained. They will drill a sufficient number of light shots to break up the coal into

sizes large enough to be saleable and small enough to be readily handled, at the same time leaving the impurities in the coal in sizes large enough to be extracted readily at the picking table and leaving the roof unshattered by excessive, improperly placed shots. Given machine drills this part of the work can be performed with minimum labor and yet with such effectiveness as to achieve the best results. Shot drillers also who are well trained and well equipped, can be relied on to shoot the coal in such manner that coal-dust explosions are less to be feared.

Accordingly, without design, the mechanical loader may help to solve four of our most difficult problems—fine coal, excessive ash, bad roof and dust explosions.

Walking Around the Block

THOSE who criticize the inefficiency of mine operations frequently draw their conclusions from some particular instance of waste which has come under their observation, but like all opinion based on superficial surveys, their judgment is often erratic.

However, any engineer, even one unfamiliar with mining conditions, upon entering almost any mine could quickly and accurately come to the conclusion that the direct-current power losses are unusually great. But he would make a grievous error if he decided without inquiry that the electrical engineer did not know his business.

Company organizations and the laws in many states are such that supervision of all inside mine equipment, after being placed in service, is directly under the mine foreman. In most cases, as it rightly should be, the first duty of the mine foreman is to get out coal. This he does, but unfortunately those men who have been placed on his pay roll to maintain the track system, to repair feeders and to install rail bonds are too frequently taken away from their regular work to "push the coal." Consequently, the power-distributing system of the mine soon becomes so bad that flagrant wastes of power become apparent. Whenever a locomotive passes, the leaky and corroded insulators, grounded feeder circuits and sparking rail joints remind us of an old-fashioned Fourth of July celebration.

Most every mine electrical engineer has had a keen realization of these conditions and has tried many plans which he thought might possibly correct the evils. Not much success has been attained because, although the work is strictly an electrical matter, he must deal with it indirectly through the mine foreman.

Now, some resourceful electrical men are getting around this obstacle by considering the repair of the feeder and return circuits adjacent to any new electrical installation a part of their work. Others are moving the power-converting equipment into the mines where it will be near the load center. Thus the feeder and return circuits are repaired or changed and given a new lease on life and are at least temporarily shortened so greatly that the power losses are largely reduced.

A NEW MACHINE enables strip-mine men to cut coal like ice. Now where's the machine that will enable them to sell it like ice, in hot weather.

WELL, ANYWAY, neither the G.O.P. steamroller nor the Democratic undercutter is a coal burner. There are other fuels.

Stone Dusting by Compressed Air

Stone Dusting:

A Means of Safety Which Helps Britain to Keep Fatality Rate One-Third as Large as Ours

Stone Dusting Is a Legal Requirement—Floors, Ribs and Roof Alike Must Be Treated—Stone-Dust Zones and Barriers Not Considered Effective Alone—Methods Employed in Dusting

BY J. A. S. RITSON

Professor of Mining, Leeds University,
Leeds, England

SOON after the erection in 1908 of an experiment station at Altofts, England, at the expense of the Mining Association of Great Britain, two facts were thoroughly demonstrated. These were: That coal dust might form an explosive mixture with air, and that fine stone dust acts as a barrier to the spread or propagation of a coal-dust explosion.

It had long been known that the fine coal scattered along haulage roads and elsewhere throughout the mines often became ignited during a gas explosion, and it was believed that it constituted a certain factor contributing to both the propagation and violence of such explosions. The experiments at Altofts, and later those conducted at the Government Station at Eskmeals, furnished data for the 1914 report of the Explosions in Mines Committee. This report stated substantially: That (1) the

maintenance throughout the haulageways of such a proportion of incombustible dust in a finely divided state as would, with the coal dust present, form a mixture containing at least 50 per cent of ash, or (2) the maintenance of at least 30 per cent of water intimately mixed with the dust along the road, or (3) a combination of these methods would prove highly effective in diminishing the force of an explosion, if not even entirely preventing its spread.

Section 62 of the Coal Mines Act of 1911 provides that: In every mine where the roof, ribs and floor are not naturally wet, (1) coal dust so far as possible must be prevented from entering the downcast shaft. In new installations, the preparation screens must be kept at least 240 ft. from the air intake. (2) Cars must be built and maintained as nearly dust-tight as possible. (3) Roads must be systematically cleaned and accumulations of coal dust prevented. (4) Systematic measures must be taken to prevent the initiation of explosions and their propagation along roads. (5) Roads

NOTE—In the headpiece a man is shown introducing stone dust into the ventilating current by means of an injector operated from the power air line. This injector much resembles the device employed for handling water. It sucks the dust from the mine car and discharges it in a cloud. This is taken up by the ventilating current and deposited on all surfaces of the heading.

Fig. 1—A Dust Barrier or Barrage

Shelves are placed along the sides of the heading as well as troughs extending across this passage just under the roof. Such barriers are often placed at the entrance to each section of the mine.

must be examined daily by a competent official who shall report the result of such examinations in a book kept at the mine for that purpose.

The "Explosives in Coal Mines Order" forbids the use of any but "permitted explosives" in mines that are dry and dusty. Furthermore, a shot may be fired only when adequate precautions have been taken to deal with any inflammable gas or coal dust that may be present.

ALL SIDES OF ROAD MUST BE TREATED

The General Regulations of July 30, 1920, in enumerating the precautions to be taken against coal dust specified:

(1) The floor, roof and sides of every road or part of a road that is accessible must be treated with incombustible dust in such a manner and at such intervals as will insure that the dust on the floor, roof and sides throughout shall always consist of a mixture containing less than 50 per cent of combustible matter. Water added to the coal dust or naturally present may be reckoned as so much incombustible.

(2) Incombustible dust used for this purpose shall contain not less than 50 per cent by weight of material capable when dry of passing a sieve with 200 meshes to the linear inch. If a larger proportion of incombustible dust is employed, however, the percentage of material of this fineness may be decreased, but must never fall below 25 per cent.

(3) The incombustible dust used must not be injurious to the health of those working in the mines.

(4) The term road as here used includes all roads from the shaft or portal to within 30 ft. of the working face.

(5) Representative samples of the mine dust must be taken by the management at least once each month and the result of the analysis posted at the mine mouth.

(6) Methods to be followed in taking and analyzing samples are legally prescribed.

These, briefly, are the chief legal requirements governing stone dusting in the mines of Great Britain. One important detail worthy of particular notice is that "floor, roof and sides" must be treated with equal care. It is not sufficient to treat merely the floor.

Stone dust is used in three ways in British mines: (a) A 50 per cent or greater mixture of incombustible matter is maintained throughout the roadways of the mine, (b) stone-dust zones to extinguish a mine explosion and prevent its propagation are provided, and (c) stone-dust barriers or barrages are installed. Legal

requirements demand that the first method shall be adopted, and as a result, it is the only one extensively employed. In many mines, however, either the second or third method of employing stone dust is used in addition to the first, because it is recognized that the first means does not or may not secure complete immunity.

Research has shown that under certain conditions an explosion can be propagated through a "50/50 mixture," but that it is difficult to initiate an explosion in dust containing 50 per cent of incombustible matter. "Incombustible dust is more effective in preventing the ignition of coal dust than in checking an inflammation that has started."

Methods *b* and *c* mentioned above do not prevent the initiation of an explosion, but will stop its spread through the mines. Throughout Great Britain the belief is general that it is wiser to prevent the initiation of an explosion than to rely on stopping one after it has started. Consequently, an attempt is made to keep 50 per cent or more of incombustible dust on all roads.

It is realized that the two chief causes of colliery explosions are defective safety lamps and shotfiring. As a result every effort is being made to improve the safety and illuminating power of the inclosed-flame lamp and to regulate shotfiring in dangerous mines until (if ever) a safe mine explosive shall be produced. Electric hand lamps are being more extensively used each year, but until a satisfactory device for gas testing, other than a flame safety lamp is produced, this latter device must continue to be used. The ancient proverb running to the effect that "prevention is better than cure" underlies present-day British practice.

DUSTING IMPROVES ILLUMINATION OF MINE

One of the results secured from the first method of stone dusting has been improved illumination of the roadways. The light-colored stone dust adheres to the sides and roof of the road and naturally reflects more light than the somber coal and roof rock. It is hoped that this may alleviate nystagmus. It has been shown by Llewellyn that the increase in illumination afforded by rock dusting varies from 100 to 400 per cent, the untreated surface reflecting 10 per cent, and the treated surface up to 55 per cent of the incident light.

The conditions which cause coal dust to be formed in the mines of Great Britain differ largely from those which cause the presence of coal dust in the mines of the United States. British mines are, as a rule, deeper than American and for the most part are worked by longwall methods. Consequently, the floor creeps and the tracks are uneven. As a result, more coal is spilled in British mines than in American during the journey from the face to the shaft bottom. Where the roof is bad, a single track is maintained and fast main-and-tail-rope haulage is employed. The speed varies from 4 to 10 miles per hour. When a full trip is coming out at, say, 8 miles per hour on the intake airway, much small coal is blown off the tops of the cars, settling on the floor, roof and sides.

The cars used in English mines are usually small and are frequently loaded well above the top of the sideboards. Attempts have been made to render these cars dust-tight, but in practice this is rarely attained. The quantity of fine dust actually produced varies between wide limits in different localities, so that whereas 2 lb. of stone dust per ton of coal hoisted is sufficient to maintain a 50/50 mixture in one district, in another it might require 10 to 12 lb.

Again, English mines are not subject to as wide variations in temperature between winter and summer as are American operations. Consequently, although the ventilating current during the winter months renders the mines drier than in summer, the difference is not as pronounced as in America. As a result, the coal dust in American mines is drier, particularly during the winter, than it is in Great Britain.

Various dusts are being employed for mixing with the coal, but Fuller's earth, shale and limestone are the more common. The Seventh Report of the Explosions in Mines Committee runs in part as follows: "Shale dust may be used with safety and powdered clay or chalk (free from flint or grit) is also practically harmless. On the other hand, there are two varieties of dust, the use of which may be injurious to health, namely, (a) dust from such rocks as ganister or sandstone that contains a large proportion of free crystalline silica which forms fine sharp-edged particles, and (b) dust of a gritty nature, such as powdered slag, clinker, flue dust and the like, which, while possibly not injurious to the lungs when mixed with coal dust, may irritate severely the eyes and throat and predispose those who breathe it to bronchial ailments."

FINENESS OF STONE DUST HIGHLY IMPORTANT

Leaving aside the considerations of health, however, this committee stated that: "The fineness of incombustible dust rather than its chemical composition affords a measure of its probable effectiveness in preventing the ignition of coal dust with which it may be mixed." Haldane has stated that "his investigations showed the dust of argillaceous shale, such as is found inter-stratified in the coal measures in most mines of the United Kingdom and which is being extensively used for coal dusting, although it contains silica, is not liable to prove a danger to health."

It is the general practice for colliery companies to install crushing machinery at the mines and pulverize coal shale to the necessary fineness for use underground. Some, however, still buy Fuller's earth or ground limestone considering it more suitable because it contains no silica.

One decided advantage possessed by limestone dust is that carbon dioxide is liberated from it by the temperature of an explosion, thus assisting in quenching the flame. In some regions, instead of crushing the rock at the individual mine, a central plant has been erected where the material is pulverized and delivered to several

Fig. 2—Side View of a Dust Barrier

Although many dust barriers are employed in British mines they are considered as aids to explosion prevention only, chief reliance being placed on the stone dust deposited on main roads.

Fig. 3—Improved Lighting Due to Stone Dusting

White dust made by pulverizing worn-out plaster of Paris molds from potteries, is blown into the ventilating current by air pressure. This is deposited upon all the roadway surfaces and whitens them.

collieries. The choice between these systems is a purely financial consideration.

In its Sixth Report, the Explosions in Mines Committee states that: "Any incombustible dust used to raise artificially the ash content of the dust on roadways should be composed so far as possible of particles capable of passing through the gauze of a safety lamp (28 S.W.G. or 784 meshes to the square inch). Shale, limestone and other dusts that have been ground so fine as to pass through a safety lamp gauze normally contain a large proportion of much finer particles, the inclusion of which is important. Experiments have shown that unless there is present approximately 50 per cent by weight of particles capable of passing through a 200x200 sieve, more than one part of incombustible dust to one part of coal dust is required to prevent the ignition of a coal-dust mixture produced by a cannon shot."

It follows, therefore, that the incombustible dust used to mix with fine coal must all pass through a 28-mesh sieve, and at least 50 per cent of it must be capable of passing a 200-mesh sieve if a 50/50 mixture is required. If less than 50 per cent passes a 200-mesh sieve, the proportion of incombustible to combustible matter must exceed 50 per cent, but that portion passing a 200-mesh sieve must in no case fall below 25 per cent.

This size of dust is obtained by grinding the materials in mills of various kinds, but usually those of the impact type. Many different varieties of pulverizing machines are on the market, such as the impact, ball, tube, pestle-and-mortar, etc. Their capacity varies from 100 lb. to 3 long tons per hour, and the horsepower required ranges from 1 to 50, depending on the quantity of material and the percentage of dust that must pass a 200-mesh sieve.

THREE METHODS OF DUST DISTRIBUTION ARE USED

In general rock dust is distributed in English mines by means of three distinct methods—hand, the ventilating current or mechanical means. In the hand method, the dust sent into the mine in bags or cars, is carried by a workman who travels with the ventilating current and throws it either with his hands or by means of a small shovel onto the sides and floor of the road. Comparatively coarse dust is thrown with considerable force so as to dislodge any fine coal with which it may come in contact. The object sought is to fill all crevices and cover all ledges with stone dust lying at its natural angle of repose, so that coal dust may not lodge upon

it but will fall to the floor where it may be swept up. In this respect the stone dust acts as an effective cleaning agent.

Fine stone dust on the other hand may be carried over appreciable distances by the ventilating current and deposited on the sides, roof and floor of the road. In many districts the shotfirers are provided with brushes. Before shooting, they sweep the roof, sides and floor to remove the fine coal dust and then apply a dressing of stone dust.

Distribution by means of the ventilating current is fairly satisfactory if the velocity of air is high. It is open to the objection, however, that a large proportion of the dust is deposited near the point where it enters the ventilating current and only a comparatively small quantity is carried an appreciable distance. According to Lovatt, a test at Birchenwood showed that 124.7 gr. of dust were deposited per square foot per hour at a distance of 60 ft. from the distributing station, whereas only 1.584 gr. were deposited at 360 ft. A larger proportion was deposited on the roof and sides at the greater distance than at the shorter.

Various methods are employed in introducing rock dust into the air current. One of these is to take advantage of the high velocities of air passing through regulators. This is satisfactory if the velocity is high enough. Only a small quantity of dust at any one time is introduced into the air current and the operation repeated until the required quantity of dust has been applied. In some instances as much as 200 lb. or more can be distributed in this manner in five minutes.

Another expedient is to place small trapdoors in the main separation doors. These trapdoors are opened and dust introduced into the air current as previously described. Still another method is to employ pipes through overcasts. The dust is introduced into these pipes and is sucked into the return airway and thus distributed.

Distribution by mechanical means is one of the most

Fig. 5—Coal-Dust Deposition in Various Districts of a Typical Colliery

Weekly observations are recorded in this instance. The graphs for each district show a marked similarity to the analogous graphs for the others. Graph A shows the percentage of incombustible material, graph B the velocity of the air current in feet per minute and graph C the total quantity of coal in tons.

common forms of spreading stone dust throughout the mines. It is, however, open to an objection that is common to all schemes which employ the ventilating current as a carrier of the dust, namely, that a large percentage of the dust is deposited near the distributing point. If, however, the dust is very fine and dry and the air current moves at a high velocity, the dust may be carried for considerable distances. Thus in South Wales instances are recorded where distinct traces of stone dust were detected 3,000 ft. from the injector. Under such circumstances as these, the stone dust is distributed in a manner quite similar to that which distributes the coal dust.

Unless the dust is extremely fine, this method is applicable only in roads less than 7 ft. square, as the velocity of the air current in larger passages would be insufficient to carry even the finest particles to any appreciable distance. As the quantity of fine dust is comparatively small in any case, it follows that the area from 150 to 300 ft. from the injector will receive an excess of the dusting material, although traces of it may be carried for as much as 1,000 yd. The quantity

Fig. 4—Rate of Coal-Dust Deposition at a Typical British Colliery

Graphs show the result of day-to-day records and analyses on three typical mine passageways. A stone crusher is located within a few yards of the downcast shaft. This accounts for the sudden upward bend

at one point in the graph for Zone A, much stone dust having fallen down the shaft and increased the percentage of incombustible dust on roof, sides and floor. Many trains of stone dust were taken over the

three zones between tests, the greatest number passing over Zone A. The velocity of the air on Zone C is only 100 ft. per minute, which is too slow to carry stone dust for any great distance.

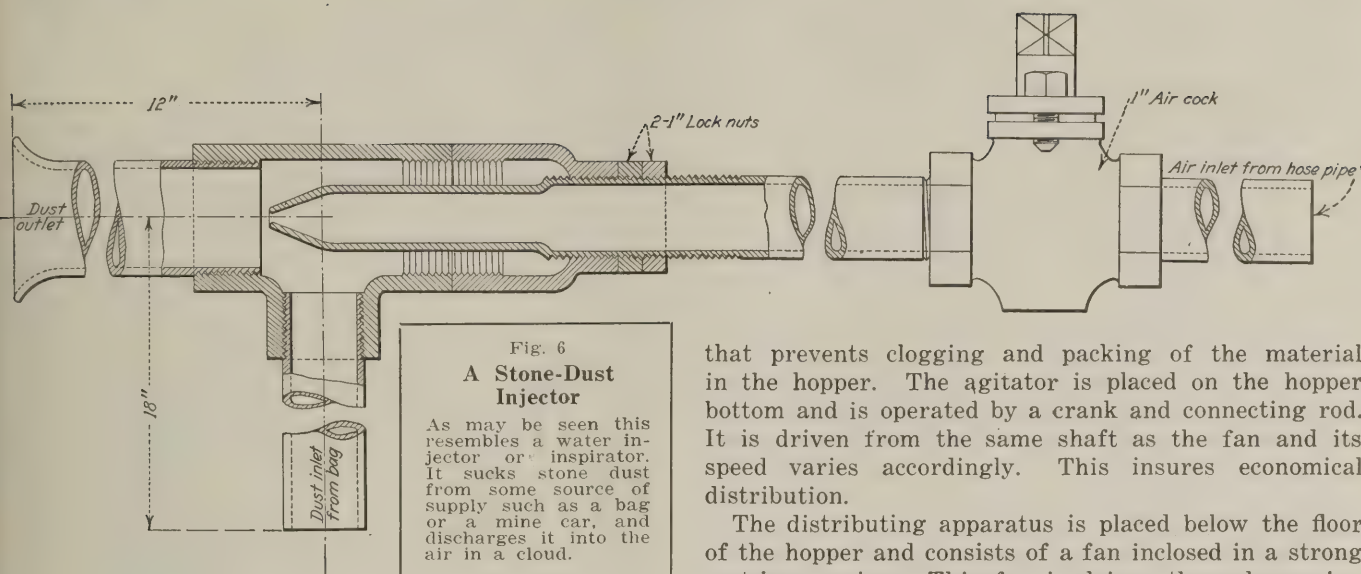

Fig. 6
A Stone-Dust
Injector

As may be seen this resembles a water injector or inspirator. It sucks stone dust from some source of supply such as a bag or a mine car, and discharges it into the air in a cloud.

deposited at such distances as this, however, is too small to be of any value.

The common form of fixed distribution apparatus consists of a hopper placed at the side of the road and filled with stone dust. In its bottom is a compressed-air injector which, when the air pressure is turned on, forces a stream of air and stone dust into the ventilating current, which carries and deposits the dust along the road. In order that this method may be of greatest efficiency, it is first necessary to remove the coal dust from the road. No satisfactory mechanical means have yet been found for performing this operation.

In South Wales compressed air has been employed to blow the coal dust from the roof and ribs. A series of fine water sprays collect the combustible dust thus dislodged. Although a large proportion of the dust was caught and brought down by these sprays, to be shoveled up later, much of the finer and consequently more dangerous particles passed through them to be deposited further inbye. Until a satisfactory means for collecting coal dust from the roadways has been devised, it is questionable if any type of stone-dusting appliance depending on the carrying power of the ventilating current will be effective. Before stone dusting is applied, the roads should be cleaned, but this frequently means only that the finer coal dust is stirred up to settle somewhere else.

INJECTOR BLOWS DUST INTO VENTILATING CURRENT

Recognizing the fact that the ventilating current forms an effective dust-carrying medium for distances less than 100 yd., an adaptation of the injector apparatus above described consists in placing distributing stations every 50 to 100 yd. Into the hoppers of these stations a bag of stone dust is poured and distributed into the air current by an injector. Another adaptation is to mount the whole apparatus on a car, which, being capable of ready transportation from place to place, is fairly satisfactory.

Yet another device which is extremely useful, particularly in mines where compressed air is not employed, is a dust distributor wherein a small fan driven from the wheels of a car forces a cloud of dust through a suitable nozzle. Probably the best known machine of this type is the Oldham stone duster. In this device the dust is carried in a steel hopper in the bottom of which is a reciprocating agitator fitted with a dust web

that prevents clogging and packing of the material in the hopper. The agitator is placed on the hopper bottom and is operated by a crank and connecting rod. It is driven from the same shaft as the fan and its speed varies accordingly. This insures economical distribution.

The distributing apparatus is placed below the floor of the hopper and consists of a fan inclosed in a strong cast-iron casing. This fan is driven through gearing from the wheel hub, a clutch being so arranged that the driving mechanism may be thrown into or out of gear at will.

DUST DISTRIBUTED INTO ROADWAY BY FAN BLAST

A dust-regulating valve is fitted to the bottom of the hopper and as the agitated dust emerges it is caught by the fan blast and distributed all over the roadway. The car may be drawn along by a pony or by mechanical means.

Table I shows the results of a test conducted with this apparatus when operating under the following conditions: The average height of the road way was 5 ft. 6 in., and its width 11 ft. The velocity of the air current was 7 ft. per second, or 420 ft. per min. The length of roadway tested was 1,200 ft.

Samples of the dust were taken from the roadway every 150 ft., as follows: First set, eight samples before dusting; second set, eight samples after the machine had made two trips, both in an outbye direction; third set, eight samples taken after the machine had made two more trips, one inbye and one outbye; fourth set, eight samples taken after the machine had made a further trip inbye. The results of the analyses set

Table I—Summary of Tests on Stone Dusting

No. of Trips of Stone Duster Along Road	Total Average Combustible Matter Present Per Cent	Total Average Reduction in Combustible Matter Present Per Cent
0	58.3	
2	46.3	12
4	35.7	22.6
5	28.2	30.1

forth in Table I, show the reduction in the quantity of combustible matter in the mine dust after two, four and five trips of the duster respectively.

As may be seen, therefore, in a roadway that had not been previously treated in any manner the dusting machine after traversing the roadway only twice reduced the combustible matter in the mine dust from an average of 58.3 per cent to 46.3 per cent. After traversing the roadway four times the combustible content of the mine dust fell to 35.7 per cent, and a fifth trip brought it down to 28.2 per cent.

HAND METHODS OF DUST SPREADING PREFERRED

Opinions differ as to which method of stone dusting is the most efficient. It is probable, however, that most people prefer hand methods, though there is much to be said in favor of traveling machines, especially where the air velocity is high. The chief advantage of hand dusting is that dust may be thrown forcibly against the ribs and roof, displacing coal dust that may be lodged there. As its angle of repose is greater than that of coal dust, both the material dislodged and the coal dust carried by the air current falls to the floor where it may be gathered up. Before attempting to remove the coal dust lying on the floor, however, it is advisable to dampen it, as otherwise a large portion of it is liable to blow away.

The provision in the Mine Regulations that "representative samples of dust from the floor, roof and sides shall be taken over a section of road not less than 50 yd. in length" is highly ambiguous and might be construed in any one of several ways. The interpretation generally accepted, however, is that this refers to an average piece of road 50 yd. in length. At 5-yd. intervals along this stretch of roadway the whole of the

Fig. 8—Front View of Oldham Machine

This car may be drawn or pushed along the track emitting its cloud of dust as it goes. This dust cloud is caught up by the ventilating current, carried along the heading or roadway to settle everywhere upon roof, ribs and bottom. Although this method of stone dusting would appear highly effective many operators prefer hand methods of dust distribution, chiefly because in hand spreading, dust may be thrown violently against the surfaces to be treated, thus displacing any coal dust that may have lodged there.

dust from a strip 6 in. wide and extending entirely around the perimeter of the passage is collected. The sample thus secured is intimately mixed and quartered down to a suitable size. Next, it is passed over a screen of 28 meshes to the linear inch, and only that portion of it passing through, retained. This is then analyzed for moisture and combustible matter in the usual way.

Special tests have been prescribed for (a) dust mixtures that contain carbonates, (b) moist dust mixtures that cannot be screened and (c) dust mixtures that contain gypsum.

In addition to the monthly samples collected by the management, the government mine inspectors take samples at nearly every mine they visit in order to to

Table II—Cost of Stone Dusting in British Mines

	Collieries		
	A	B	C
Output of coal (gross tons) during period under consideration	11,500	194,935	3,500
Gross tons of stone dust used during same period	25	367	4
Stone dust used per ton of coal produced	4.9 lb.	4.21 lb.	2.5 lb.
Cost of stone dust per ton	\$4.86	\$1.02	\$3.54
Cost of handling and distributing stone dust per ton	\$2.25	\$9.54	\$3.63
Cost of stone dusting per gross ton of coal produced	1.64c	0.426c	0.811c

satisfy themselves that really representative samples are being taken by the mine authorities.

It is difficult to state average costs of stone dusting, as conditions vary widely. The actual expense is influenced by the following factors: Length of road, quantity of coal passing over it, nature of coal and rate of deposition of coal dust, which itself is influenced by the type of car, condition of track, kind of haulage and the method of working the mine. On the basis of coal output, some mines require only 1 lb. of stone dust for each ton of coal produced, whereas others require from 10 to 12 lb. It will be seen, therefore, that costs may vary between wide limits. Some typical costs, however, are set forth in Table II.

PRIMARY CONSIDERATIONS OF STONE DUSTING

To summarize, the most important points observed in British stone dusting practice may be enumerated under the following eight headings:

- (1) The fineness of the stone dust used is the most important factor.
- (2) At least 50 per cent incombustible matter should be maintained in the dust of roadways.
- (3) No dust dangerous to health may be employed.
- (4) It is better to prevent the initiation of an explosion than to concentrate efforts on stopping it after it has once started.
- (5) Careful attention should be paid to methods of shotfiring and the type and condition of safety lamps used.
- (6) Dust should be regularly cleaned from the roads.
- (7) Stone dust should be distributed regularly either by hand or mechanical means.
- (8) Regular and systematic sampling and analysis should be practiced in order that the condition of the roads and traveling ways may be at all times known.

Ballistic Mortar Tests.—A ballistic mortar, with aluminum suspension plates of the type generally used by explosive manufacturers, has been installed at the explosives' laboratory of the Bureau of Mines at Pittsburgh, Pa. This apparatus will be used to determine the deflective force of commercial and military explosives, and to correlate the results obtained with the Bureau of Mines' type of mortar with results obtained by manufacturers.

Rugged All-Steel Sectional Portable Conveyor Co-ordinates Mining and Haulage

Constructed in Short Sections Each of Which Can Be Carried by Two Men—Pins Are Used Instead of Bolts as Fastenings—Several Motors Used When Long Conveyor Is to Be Driven—Machine Easily Shifted

MECANICAL loaders capable of handling coal within the mine at capacities up to 4 tons per minute, have caused operators to begin search for some kind of continuously-moving mechanical device capable of transferring this coal from the shovel at the face to the room neck, to a sidetrack or even to the tippie itself. By means of a suitable mine layout and the aid of conveyors, they hope to keep their loading machines in operation during a far larger percentage of the time than hitherto has been possible. This would increase the efficiency of labor and limit the area of live workings. The conveyor described in this article forms a connecting link of any desired length between the loader in the room and the mine car in the heading.

Several years ago Walter D. Stockly, now general manager of the American Mine Equipment Co., of Pittsburgh, Pa., on behalf of a large coal company, investi-

NOTE—Headpiece shows a 200-ft. conveyor fitted with two driving sections, each equipped with a 5-hp. motor. The uneven meadow land upon which this unit is set up clearly demonstrates its flexibility.

gated the performance of an electric loading machine in operation in one of the coal company's mines. He found that the machine itself was correctly designed, well built and when in operation handled coal cheaply and at a rate exceeding a ton per minute. So much time, however, was lost in switching cars to and from the machine and so many other delays and expenses were encountered that the coal loaded mechanically cost as much as that loaded by hand in other parts of the mine.

Heretofore, this has been the chief obstacle to machine loading. After this investigation much thought was expended on ways and means for surmounting the difficulties encountered. It became obvious that if a suit-

able portable conveyor could be designed that would remove the coal as fast as a shoveling machine could handle it, the cars could be loaded in the heading and the filling of cars would become much more nearly a continuous operation. A smaller crew would be necessary, and costs would be decreased.

Learning after a time that the West Virginia Coal & Coke Co., of Elkins, W. Va., was working upon a similar idea and attempting to produce coal by modified longwall operation by the aid of conveyors, Mr. Stockly joined his efforts with those of this coal company. Basic designs of what is now known as the Movor conveyor were thus developed. This device was mentioned in the Feb. 7 issue of *Coal Age*, p. 197, in describing what is known as the V-system of mining.

A PORTABLE CONVEYOR IS DEVELOPED

The Movor conveyor is of the pan-belt type, built entirely of steel and is portable, because it is sectional. A unit must comprise four parts: a head, a curved, a drive and a tail section. As many straight sections may be added as are needed to secure the desired length. If, however, the number necessary is more than can be actuated by one drive section, additional drive sections may be added at will.

All sections, except those forming the head and tail of the conveyor, are interchangeable so that a unit of any length may be built up. If greater rise is required at the delivery end than is afforded by the curved section, one or more straight sections may be interposed between it and the head section, so that any height of discharge may be attained.

In short, the design of this conveyor is such that great flexibility is obtained. All motors normally used for driving the conveyor on level ground, regardless of its width or capacity, are of 5 hp. Such a motor is capable of actuating about 100 ft. of 20-in., or 70 to 80 ft. of 36-in. pan belt. Conveyors longer than those mentioned require two or more drive units, each operating independently of, but in synchronism with the others.

Each section of this conveyor is complete in itself. This greatly facilitates the assembly or transportation of a unit. Two elements are common to all sections, namely, the frame (the shape of which differs for each type of section) and the pan belt which is of standard design and common to all sections. The frame elements are built up of angles and plates securely riveted together. They are joined end to end by means of slotted pins fitted with wedge shaped keys, the details of which may be clearly seen in several of the accompanying illustrations.

The belt is composed of pans, pressed from $\frac{1}{2}$ -in. steel plate, to the back of which are riveted or bolted two flat steel hinge bars or links; axles passing through the eyes of these bars couple adjacent pans together. These axles carry the supporting flanged wheels which run on tracks attached to the frame. Each wheel is held in place by a washer and a spring clip that fits into a suitable groove in the axle. The belt is driven by sprockets acting on the wheels.

This construction entails the use of a minimum number of parts. The axles serve as pins joining together the hinged bars which in turn form part of the pan. The wheels support the load, hold the axles in position and are acted upon by the driving sprockets. The spring-clip retainers fastening the wheels in place can be quickly applied or removed without the use of tools.

For use in rooms and other places where the quantity of coal to be handled does not exceed 100 tons per hour,

Fig. 3—Head or Discharge Section

The pans make the turn at the end of the conveyor by passing around suitable sheave or turn wheels. The bearing and return tracks on this section are somewhat divergent to enable the belt to make the turn.

the conveyor pans are 20 in. wide, 4 in. high and have a pitch of 9 in. Such a conveyor has a calculated capacity, when carrying loose coal, of 1 ton per hour for each foot of conveyor travel per minute. At a speed of 100 ft. per min., therefore, such a conveyor has a calculated capacity of 100 tons per hour. In performance, however, the capacity actually obtained is somewhat greater than this. For ordinary use, the speed of travel is reduced to 50 ft. per minute, giving a corresponding capacity of 50 tons per hour.

WIDE UNITS USED ON HEADINGS

Main-line units that receive coal from a number of 20-in. feeders are made 36 in. wide and have sides 6 in. high. Aside from the increased width and height of such conveyors, all elements and parts, such as wheels, wheel retainers, motors and speed reducers are the same on the large units as on the small ones and are interchangeable with them. The capacity of a wide unit, however, is roughly eight times that of the small or auxiliary unit.

Even when carrying this heavy load little spillage occurs, only an occasional lump rolling from the moving pile which is $1\frac{1}{2}$ to 2 ft. high at the center of the pan belt.

Tracks on the head section diverge sufficiently to permit the belt to round the sheaves or turn wheels, as may be seen in Fig. 3. Next to the head section normally is placed a curved section which differs from a straight

one only in that by it a gentle change in direction of the track is obtained. This is necessary in order to gain the necessary headroom for the discharge of the coal. As may be seen in Fig. 4, the head and curved sections are supported in normal position by means of timber blocks.

A head section placed as has just been described gives a proper elevation for discharge into a main-line conveyor. If the coal is to be discharged into a mine car, a straight section is interposed between the curved and the head sections. When this is done, the conveyor is sufficiently flexible so that a foot or more of difference in elevation above or below the normal discharge position may be obtained.

HEIGHT OF CONVEYOR ONLY EIGHTEEN INCHES

Little need be said as to the straight sections, for Fig. 5 shows much of their detail. In any ordinary conveyor the number of these sections employed predominate, and fortunately they are the simplest in both design and construction. The height of these sections is 18 in., making the conveyor suitable for use in a 3-ft. coal bed.

A typical drive section is illustrated in Fig. 6, and Fig. 1 shows it in both plan and elevation. Drive sections are interchangeable with straight ones. In a section of this kind, however, the upper track is humped slightly upward and the lower one has a similar curve, but in an opposite direction so that room is made between them for the driving sprockets which engage the wheels of the pan belt. The drive mechanism is simple, both in design and operation. The contours of the driving-sprocket teeth are true involutes, imparting a uniform movement to the pan belt with little of the jerk and slap inherent to conveyors driven at one end.

Both upper and lower runs of the pan belt are engaged by the sprockets simultaneously, and as the belt is adjusted by a take-up on the tail section, there is little slack at either end. Consequently, wear on the hinge bars and axles due to rounding the end sections does not exceed that in traveling horizontally.

By relieving the tension at the ends of the conveyor excessive wear is eliminated, and the maintenance cost is thereby reduced. Because of the smoothness of the drive, this conveyor can be operated at high speed. Application has been made for broad patents covering the drive and other details.

Two or more drive sections embodied in a single unit function as smoothly as one. When properly placed,

each takes an equal portion of the load and the stresses on any part as compared with those existing in a conveyor of equal length provided with only one drive, are reduced to a fraction, of which the numerator is one and the denominator the number of drive sections employed. Apportioning the load on a long unit to two or more drive sections, reduces the size and weight of each, thus giving portability to the entire equipment.

The gear reductions employed on the drive sections are equal in quality to the transmission of a high-grade

Fig. 5—Straight Entry and Face Sections

The central section shown in this illustration is the type employed on entries. Its frame carries two angle irons which serve as bearing and return tracks for the pan wheels. The section on the right is intended for use at a face. The frame of this section carries two additional angle irons that retain the wheels and prevent derailment in case of a fall of roof or coal.

automobile. Gears and gear shafts are made of carefully heat-treated alloy steel. They operate in oil-tight housings and are carried on high-duty precision roller bearings.

The tracks on the tail section like those at the discharge end of the conveyor are made slightly divergent to facilitate the transfer of the pan belt from the lower to the upper run, as may be seen in Fig. 7. The tail sections are also provided with suitable sheaves or turn wheels. Unlike the head sections, however, the tail sections are provided with take-ups not only to compensate for the elongation of the moving parts as the result of wear but also to facilitate the insertion or removal of various sections by taking up or paying out slack in the pan belt.

This conveyor is of simple design and rugged construction. The two primary objects sought were low maintenance cost and the expenditure of the least possible time and effort in assembling or dismantling a unit. Every man experienced in underground management knows that bolts and nuts, exposed to the humid atmosphere encountered in the mine, as well as to the acid water dripping from the roof or collecting in pools on the floor, should be avoided if possible.

BOLTS AND NUTS CONFINED TO DRIVE SECTION

He knows full well the state of mind of a workman who encounters a nut which is rusted fast to its bolt or has been cross-threaded upon it; he has often heard the outbursts of "cussing" as such a man attempts to manipulate two wrenches, one to hold the bolt from turning and the other to remove the nut. Skinned knuckles or bruised hands are liable to result. In the Movor conveyor, bolts and nuts are confined to the drive section. It is necessary to remove only a few of them in dismantling prior to moving the conveyor. These are of such large size as not to be lost or misplaced easily.

For the addition or removal of one or more sections of the conveyor, a crew of only two men is required. When the unit is to be lengthened, one man works on either side of the conveyor. First the take-up screws on the tail section are backed off to give the pan belt a certain amount of slack. Then the spring clips retaining a

Fig. 4—A Typical Curved Section

When one conveyor discharges onto another a curved section is adjacent to the head section: when however discharge is made to a mine car a straight section is interposed between head and curved sections. This is done in order to gain the necessary height for the coal discharge. Note the slotted pins and wedge keys holding the frames of adjoining sections together.

Fig. 6—A Conveyor Drive Section

In moving a conveyor unit each drive section may be separated into five elements. These are: Motor, speed reduction gear, bracket, frame and pan belt. Each may be handled separately.

wheel on both the loaded and return strands of the pan belt are removed from one side of the conveyor and the axles are pulled out by the man on the other side. Next the wedges are knocked out of the slotted pins fastening the tail section to the adjoining section, after which the tail section is pulled away a sufficient distance to accommodate as many additional straight sections as are desired. These, together with a strand of pan belt on both the upper and lower tracks, are then pushed into place. The frames of the various sections are fastened, end to end, by means of the slotted pins and wedge keys; the ends of the pans are brought together; axles, wheels and spring clips are replaced, and after the take-up screws have been tightened to afford the proper tension, the conveyor unit is ready for operation. Substantially the reverse procedure is followed in shortening a unit. One straight section can be added or removed by experienced men in 15 min. or less.

AN UNCOUPLED UNIT IS EASILY MOVED

The ruggedness of this conveyor does not detract from its portability in sections or in elements. When assembled, so flexible a unit is formed that it may be shifted bodily throughout short distances, either sidewise or endwise, without injury to any part. For this purpose, a block and tackle, a post puller or the chain or cable of a mining machine may be used. Shifting either endwise or sidewise is facilitated by two U-shaped steel straps forming part of each section. These pass under the frame, and the weight of the conveyor rests upon

them. In making a shift, they serve the same purpose as the runners on a sled.

When a unit must be moved from one face to another, or from entry to entry, it must of course be dismantled and the transfer made in sections and elements. The head and tail sections are respectively $3\frac{1}{2}$ and $5\frac{1}{2}$ ft. in length. All other sections are 6 ft. long. The frame elements of the head, tail, straight and curved sections weigh about 200 lb. each and are thus a load for two men. The pan belt proper is removed from the frame and moved separately. One man can handle 3 ft. of it weighing about 120 lb. The heavy elements of the drive section, such as the frame, motor and gear box weigh from 300 to 600 lb. each and consequently require a truck for moving over any great distance. Several thousand feet of this conveyor in an old section of a

Fig. 7—Tail Section of the Conveyor

In appearance the tail section much resembles the head section. The tail section however is provided with a pair of takeups to permit of quickly adjusting the tension on the pan belt.

mine has been dismantled, moved a distance of 2,000 to 3,000 ft. to a new location, and assembled again, all within the space of two days.

Not only is this conveyor suitable for transporting coal over level ground, but it may be used on slopes as well. A unit 500 ft. long on a 30-deg. pitch will have a rise of about 250 ft. Eight drive sections at intervals of 60 ft., each equipped with a 25-hp. motor will move the coal at the rate of 500 tons per hour. The cost of this equipment, for a slope of the characteristics outlined, is less than that necessary for shaft equipment of equal capacity.

What Anthracite Region Is Doing to Make Fine Sizes of Coal More Readily Salable

Jigging, Tabling and Floating Are Cleaning Processes in Use—Jigs Now Operate Without Suction and Stratification Occurs in Quiescent Liquid—Whole Art in State of Flux

BY FRANK H. KNEELAND
Associate Editor, *Coal Age*.
New York City

“HOW to dispose of the small sizes,” said a hard-coal man recently, “is the nightmare of the anthracite operator.” Every little while the problem seems nearer solution, but a new factor will enter to make success less certain. It is true that the finer sizes can be used today more widely than ever before. Automatic stokers have made them available for industrial use. Special devices have enabled householders and apartment-house keepers to use them for domestic heating. It has been demonstrated also that, after pulverizing, this coal can be burned suspended in air, and briquetting has furnished another means of using anthracite fines.

During the war the use of bituminous coal in place of anthracite was greatly extended, better combustion and coal shortage making municipal authorities lenient. Oil, coke, gas and even bituminous coal commenced to drive out anthracite and those enterprising persons who were disposed to adopt a new and cheap fuel like buckwheat were lured, in many instances, to other fuels promising some advantage or convenience.

MUST FREE FINE SIZES OF IMPURITY

Anthracite small sizes have therefore a hard fight before them, and to fit them for the battle it is necessary to free them from the ash which reduces their heating equivalents. They cannot be hand picked. It would be an endless task to clean by hand a ton of No. 2 buckwheat, for instance, and the cost would be altogether out of proportion to the enhanced market value of the fuel. But the coal must be cleaned, so producers have been seeking with diligence mechanical means for cleaning their small sizes while not neglecting the opportunity to improve the treatment of their larger coal.

As a result many devices for screening, picking and washing within a comparatively short time, have been developed and placed on the market. Among these might be mentioned the “W-dent” screen plate and the Mason flat slate picker; also various machines such as the Reilly-Knapp, the Ransom, the James jigs, the Wilmot valve-plunger jig and another type now in the embryo stage, concerning which little can be said at present except that the laboratory model has given excellent results. These have been supplemented by such other coal-cleaning devices as the various concentrating tables, the Chance separator, the Rheo-Washer and more recently by another machine as yet unnamed which gives promise of excellent results. A few of these will be described.

One of the newer coal-cleaning devices now being used, but one that has been tried long enough to demonstrate thoroughly its practicability is the Ransom jig. This machine is so designed that it separates the coal

from the impurities accompanying it by means of upward pulsations of water only, the product to be treated being allowed to settle freely in a practically quiescent liquid.

To obtain this action a plunger operating in compartment A, (see Fig. 1) is fitted with light valves opening downward. These valves therefore open on the up and close on the down stroke. In the side of this compartment is placed a series of deflection vanes which give the water an upward motion as it enters the screen or separation compartment B. Light valves are also placed in the wall of this compartment preventing any backflow of the water as the direction of the plunger movement changes.

In operation, the feed, consisting of the mixture of coal and slate just as it comes from the screens, enters the jig in the usual manner, gaining access to the screen compartment by passing under a gate. On the screen C the coal is subjected only to upward pulsations of

Fig. 1—Plan and Elevation of Ransom Jig

Because of the valves in the bottom of the plunger and those in the side of the screen compartment, water is forced through the screen in a series of upward pulsations without appreciable back suction. The bed of material being jigged is thus lifted sharply from the screen and allowed to settle back in practically quiescent water.

Fig. 2—Section Through Valve-Plunger Jig

As the plunger moves up and down the valves, which open upward, cause the water to be forced up through the screen in a series of pulsations. The action on the material jigged is much the same as that secured in the machine shown in Fig. 1, settlement of the bed taking place in practically still water.

water from the plunger compartment, the valves preventing any back flow, or back suction. The bed of material jigged is thus lifted from the screen and allowed to settle back in practically still water.

PARTICLES SETTLE IN QUIESCENT WATER

Naturally the particles stratify according to their respective specific gravities, that is, the pieces of highest specific gravity seek the bottom, those somewhat lighter coming next and those of least specific gravity, or the pure coal, seeking the top of the jig bed. Not only is the stratification more perfect, but the grinding of particles against each other is less pronounced in a machine of this kind, where the material in the jig is first agitated and then allowed to settle freely than where the pulsations of water are alternately upward and downward.

When stratification has become complete the good coal overflows notches at the sides of the jiggling compartment and is withdrawn by two conveyors, one upon either side of the machine. The slate is drawn off through the automatic gate *D* and is removed by another conveyor.

The thickness of the bed of rock maintained on the screen surface may be varied at will by manipulation of the gate *D*. The valves on the lower surface of the plunger and in the side of the jig compartment are made from strips of balata belting fastened along one edge. Their action is therefore so light and positive that if the flow of water to the plunger compartment is shut off the liquid is promptly pumped down below the reach of the plunger.

WILL CLEAN PEA AND SMALLER COAL

This jig is especially adapted to the treatment of the finer sizes of anthracite, being ordinarily used to clean pea and smaller coal. Some of the results secured from it follow: During November, 1923, three tests, one of 4-hr. and two of 7-hr. duration, were run on three successive days, the machine at that time operating on No. 1 buckwheat. Throughout these tests samples were taken of both the coal and refuse every 20 min. to a half hour with the following results: Maximum quantity of coal in rock discharge 8 per cent; minimum, 6 per cent; average 7½ per cent. The quantity of slate

in the coal discharge showed no variation, being 3 per cent in all cases.

Another washing device that has made its appearance within comparatively recent months is that known as the Wilmot valve-plunger jig. A cross-section of the bed of material being treated in this machine is shown in Fig. 2. This jig also employs the cup-and-gate refuse discharge on anthracite sizes smaller than ¾ in. This, however, may be used also on larger sizes.

In this machine the jig box is divided into three main divisions designated in Fig. 2 as *A*, *B* and *C*. Sized coal as it comes from the screens enters the feed hopper *A*. Thence it passes under the adjustable gate *D* into the jiggling compartment *B*. Here it stratifies under the action of pulsations of water from below, heavy pieces going to the bottom and the good coal, which is lighter, seeking the top of the jig bed. Accordingly the coal overflows at *E*, and the slate escapes through the refuse compartment *C* and over the gate *G*.

In this jig the water is given a series of upward pulsations. The plunger *J* is actuated through the connecting rods *I* by the eccentrics *H*. In the top of the plunger is placed a series of light valves *K* that open on the downstroke but close on the upstroke forcing water through the screen *L* in pulsations much like those from an ordinary hand pump.

As may be seen the screen *L* is set at a slight inclination. The gates *D*, *F* and *G* are all adjustable so that the feed going to the machine as well as the slate discharge may be readily controlled. The slushing gate *M* is opened occasionally to free the space above the plunger from any fine material that may have found its way downward through the screen *L*.

DISCHARGE GATES REMOVE DIFFERENT PRODUCTS

The heights of the discharge gates have been determined in accordance with the specific gravities and sizes of the materials handled. As a rule the height of the coal overflow is left stationary, and the slate gate is adjusted to suit the material treated. If the slate gate is too low some coal will pass over with the refuse; if too high slate will go over with the coal.

The capacity of this jig varies approximately as the

Fig. 3—Cross Section of the Basket-Type Jig

In this machine the basket or pan is moved up and down in a tank of water. The coal is thus washed in much the same manner as it has been cleaned by hand by the Chinese for centuries. This is perhaps the simplest jig of all.

speed of the eccentric shaft. When operating at 140 r.p.m. on buckwheat material passing over a $\frac{1}{4}$ -in. and through a $\frac{1}{2}$ -in. circular opening, one of these machines gave the following results:

Quality of feed, 30 per cent slate, 70 per cent coal; after jiggging the coal, discharge contained 8 per cent slate and 92 per cent good coal; the slate discharge contained 1 per cent of coal.

At the time this test was made the machine was taking feed at the rate of 25 tons per hour. It thus will be seen that although the machine is somewhat bulky its capacity is large. It is designed and built to withstand the hard and continuous work to which all machines of this kind inevitably are subjected.

BASKET, OR PAN, JIG AND PLUNGER JIG

Jigs of many different kinds have been perfected and placed on the market. In general these all embody the same cleaning principle although they are of two distinct types, namely, the basket, or pan jig and the plunger jig. In the basket jig (see Fig. 3) the whole compartment or pan containing the materials to be

Fig. 4—A Plunger Jig Without Valves

Here the water is caused to surge or pulsate back and forth through the screen and the material supported by it by means of a plunger. Slate is discharged to one conveyor and coal to the other. This machine as well as that shown in Fig. 3 appears to be somewhat better adapted to treating the larger sizes of coal than the smaller.

separated is reciprocated up and down in a tank of water. In the plunger type of machine (Figs. 1, 2, 4 and 5) the coal container is held stationary while movement of the water is caused by a plunger.

In any case a jig, although fairly efficient in operation, is a big, heavy machine requiring much floor space. For treating the finer sizes in particular, operators have sought means less bulky and ponderous. To this end concentrating tables have been installed in appreciable numbers. Like the jigs they are of several types but all operate upon the principle that, on a reciprocating table, material of high specific gravity will follow along the riffles of the table while that of light specific gravity will be washed over them.

Various attempts also have been made to separate coal from its accompanying rock by means of flotation. Of these devices thus far perfected the Chance flotation apparatus is probably the best known. In this process a high specific gravity is imparted to water by intimately mixing fine sand with it and retaining this sand in suspension by continuous agitation. This device as well as the construction of a washery employing

Fig. 5—Pulsator and Bed of the James Jig

In this machine the plunger or pulsator as it is called is provided with valves so that a series of upward pulsations is imparted to the water acting on the jig bed. The action of this machine is similar to that of the jigs shown in Figs. 1 and 2.

it was described in *Coal Age* of May 4, 1922, page 735. Another article appeared May 1, 1924, p. 633. Being a flotation process, it is not necessary to size the coal before separating the impurities from it.

DEPENDS ON SEVERAL PRINCIPLES OF SEGREGATION

More recently the Rheolaveur, or Rheo-Washer, has made its appearance from Belgium. Although this machine itself is extremely simple, the principle of its operation is somewhat complex as advantage is taken of several properties of coal and slate or rock when immersed in water. This device was described in *Coal Age* of Dec. 6, 1923, page 847, also in the issue of Mar. 27, 1924, page 455. It is now being tried out in the anthracite region.

The whole art of anthracite preparation appears to be in a state of flux; a machine which today may be considered the "last word" in coal preparation tomorrow may be obsolete. Great progress has already been made but present average practice still leaves much to be desired. The small sizes as they come from the shakers in many cases not only contain a larger percentage of impurities than do the larger grades, but unlike the larger sizes, they cannot be hand picked. Of necessity, therefore, the coal producer must look to mechanical means, appliances and processes to clean his small coal if it is to compete in the open market with other fuels.

OPEN LIGHT, THE OPEN ROAD TO DISASTER—A recent study of the disaster files of the U. S. Bureau of Mines covering a period of seventeen years reveals the fact that open lights and gas have been the attributed cause of seven fires and 102 explosions in coal mines and of four fires in metal mines, in the United States. Tabulation of the data shows that these disasters were responsible for the death of 2,341 men, injury to 376 and great damage to property—in some instances the mine being entirely wrecked.

Cost-Cutting Suggestions for the Mine Executive

Savings in the Past Testify to the Possibilities of the Present—Automatic Equipment Saves Labor, Eliminates Accident and Is More Dependable Than a Station Tender—Super-Power Practice Adaptable to Mine Conditions

BY EDGAR GEALY
Associate Editor, *Coal Age*

IN the next three years as much advance will be made in coal-mine equipment as in the past seven years," said a prominent mining engineer recently, and the interest of the mining public in the possibilities of mechanization amply justify his statement.

Almost every man now working with his muscles can perform his labor easier, cheaper and better by the aid of equipment, for the human body is slower, weaker and less efficient than the machine and the human eye and ear less attentive and responsive than electrical apparatus.

Though the miner must perforce cut his kerf in the bottom, the machine cutter will put the kerf where it will do the most good, at the top, bottom or in the

center of the seam. It even will cut out a dirt streak. It will cut a deeper kerf also so that the coal on shooting will fall in lumps of marketable size. When power drills are used, shotholes can be better placed than when drilled by hand.

Loading machines work so rapidly that when they are used, less timbering is needed and the coal is extracted and the place is vacated before the bottom heaves and the drawslate falls, and both have to be removed. Storage-battery locomotives reduce operating charges, for they will not only haul more cars than mules but they also "eat no hay" when the mine is idle, and in low coal they save much deadwork. Haulage locomotives transport more coal in a trip and move at

Inside Power Station

More and more, transformer and power-converting apparatus are being installed in the mines. In some respects this is due to the need for a shortening of feeder cables. Many engineers find that this is the only way to minimize the effects of bad bonding.

higher speed, saving in manual labor and making possible the delivery of more cars. The replacement of steam by electricity also serves to save power, for electric hoists use power only when raising loads, preventing the waste of steam and heat when the hoist is not running.

Automatic apparatus not only saves labor but responds more promptly to demands made upon it than do the men who are put in charge of substations not thus equipped. They put the power at proper voltages where it is needed. Line and feeder control devices maintain the power on circuits and localize troubles which otherwise might shut down the entire plant and lower the morale of the working force.

Not only are the new devices more certain, effective and economical, but they also afford greater safety. Control apparatus not only automatically starts and stops equipment, but some of these accessories operating with a certainty almost uncanny protect both equipment and workmen. Many machines are started and stopped by remote control so that the workman who sets them in motion or stops them is at no time in danger. A relatively new use for electricity is gangway and face illumination and its introduction has greatly reduced mine hazards.

Increased speed is the keynote of success in the coal industry; every operation must be speeded up to keep in step with the fastest moving equipment. Most important of all is the continuous flow of coal, so that every machine and man will be able to devote full time in productive effort. Friction, the bane of speed and production, is being greatly reduced. Anti-friction bearings, applied to mine cars and idler pulleys for long conveyor-belt systems, lower energy costs and increase the capacity of present power units.

PROOF THAT BETTER EQUIPMENT LOWERS COST

It is an undisputed fact that these changes will greatly reduce operating costs. Where long steam pipes have been replaced by electric power lines the investment in many instances has been returned in two or three years. One large mining company, almost completely electrified, is now generating more power than the public-utility company which supplies the principal city and the adjoining municipalities of that same region. This coal company is now spending \$1,000,000 to increase the capacity of a single power plant. The

Safe Enough for Anyone

By supplying the workman with power-driven machinery which he can operate safely, half the work of gathering cars on the main branches is done before the gathering locomotive returns for another trip.

engineers have determined that electrification of the hoisting shafts will save \$600,000 annually.

There is not a coal company anywhere which cannot reduce its costs by a further application of machinery. From a survey of the field it is obvious that much new machinery has been so well developed that its effect in cutting cost can be predicted with confidence. Nearly every company is doing at least some one thing better than the others, and valuable information can be gathered by an interchange of ideas.

Then too, ingenuity and competition for business have resulted in the design of many labor-saving devices. One large company has made wonderful savings by better control of the direct-current distributing lines. The principle of the super-power system, that promises so much in national development, has been adapted to render more economical the operation of the power systems of individual companies. Circuits have been arranged and protected so that, during peak loads, power can be taken from several different substations. As a consequence most of the generating equipment operates continually at a high load factor. Furthermore, by the use of substations the generation of direct current is located close to the machinery to be operated so that there are no long power lines and defective return circuits.

Another company is now using large fan motors which can be slowed down, thus saving power during

Fan Motor Lowers Costs

Fans are large consumers of power. If the energy consumed by a 100-hp. fan motor could be cut in half during the night hours the power thus saved would be sufficient to run three 100-hp. hoist motors during the operating day. Such savings as these are not obvious but they can be made with little effort and expense.

Rescue Apparatus Pays Profits

When an accident occurs every minute means money and anxiety. Fire-fighting equipment when readily available may quickly return its investment. Dangers multiply and fires quickly spread when not combated immediately. Idle periods occasioned by accidents eat up the profits, for they usually occur when the market is good.

idle periods, nights and holidays. Where some of these motors have been installed the power costs during two-thirds of the twenty-four-hour day have been halved.

Storage batteries used on locomotives, cagers and coal cutters often bring about great savings. Yet the possibilities of this development are as yet but inadequately recognized. Batteries recharged at night do much to minimize the daily peak load, for which the consumer usually pays a fancy charge whether it be to his own power plant or the power company. Rotary converters which supply energy during the day to trolley locomotives, cutters, etc. are often used during the night to charge storage batteries. Where 110-volt batteries are used large savings of power are made by placing the battery in the circuit between one line wire and a neutral point on the rotary transformer bank.

Storage batteries are now frequently put on charge and given little or no further attention until morning. By means of ampere-hour meters with suitable contacts, the high charging rate is lowered at a predetermined time and finally terminated. When the last battery is fully charged the power-converting machine is shut down by a load control relay or a time clock.

The power loss resulting from poor bonding is not fully realized or appreciated. Most of the bonding work comes under the direct supervision of a mine foreman and consequently is often left undone. Electrical engineers are now endeavoring to overcome this evil by making the repair of the return circuit a part of their work whenever they install any new apparatus in the mine. Others are surmounting the difficulty by placing the substations so near the center of the loads that the feeder and return circuits are short, thus reducing the voltage drop.

Heretofore, lightning arresters have been used almost exclusively on power lines exposed to atmospheric lightning, but lately many new types of such apparatus have been developed and these have been applied where owing to grounds, short-circuits and switching operations, abnormal voltages are built up. The added protection thus afforded has often checked line disturbances which hitherto have greatly damaged electrical equipment.

Static condensers located where they can correct lagging power factor offer wonderful opportunities to increase the kilowatt capacity of transformers, power

lines, switches and generators. Synchronous motor-generator sets once located where they could best correct the lagging power-factor of tiddle and breaker drives can now be transferred to the mine where they can deliver full voltage to the mining machinery. Thus burnouts will be less frequent, power losses will be diminished and higher operating speeds attained.

Obviously, we are seeing revolutionary changes; factory methods are being adopted and these enable the operator to get out his product at minimum cost. Thus intensively performed mining will bring in a profit every working day.

Keep Open-Flame Lamp from Coal Mines

By L. C. Ilsley and M. W. von Bernewitz*

Several hundred thousand open lights are carried daily in coal mines of the United States, each lamp being a menace to light and property through fire or explosion. They have been responsible for many disasters in the past and will be again. Flame safety lamps have been available for over a hundred years, but during the last ten years safe and practical electric lamps have been perfected. These have eliminated many of the flame safety lamps and in a few mines have replaced open-flame lamps.

But there are still more than twice as many open lamps as electric lamps in our mines, and the open lamps should be discarded in favor of an approved type of electric lamp. There are several electric miners' lamps which have been approved by the Bureau of Mines for safety and efficiency which give a good light and are easily maintained and carried. Some flame safety lamps will always be used, but mostly for detecting gas, although they might be supplanted if some simple, reliable and cheap gas detector were developed.

An open light and gas combine to form a vicious hazard, and if any coal dust is present in the vicinity the consequences are multiplied many times. An open light and black blasting powder also constitute an explosion hazard, as has been vividly attested by several serious disasters.

*Electrical Engineer and Mining and Metallurgical Engineer, respectively, U. S. Bureau of Mines.

Give Loading Machine the Chance It Deserves

Every Mine Installing Machines Should Work Out a System of Operation—The One Presented Should Enable Six Machines to Produce 1,500 Tons Per Day from Twenty-Four Places.

BY CHARLES GOTTSCHALK
Mining Engineer, Evansville, Ind.

IN THE development and adoption of mechanical loading underground, the past year has been an important one for both mine operator and manufacturer. During the formative period, the pioneers are many, and not all can succeed. In the case of mechanical loading this has proved true of both the mine operator and the manufacturer. Fortunately, however, the net result of combined efforts has been a demonstration by several mine owners of their ability to install mechan-

chines always requires the expenditure of appreciable sums of money. To make these investments pay dividends, the management must provide continuity of operation for such machinery. This sounds easy; unfortunately, however, failure to observe this fundamental principle has done more to disappoint investors in loaders than any other consideration.

In order to illustrate the thought in mind, a plan for the operation of mechanical loaders is shown in the accompanying sketches, Figs. 1, 2 and 3. A room section conforming to the standard dimensions adopted in a certain large producing field has been selected as a basis, and a layout suggested that will conform with the plans of a mine operated on the room-and-pillar system. This layout and the successive steps followed in the development of the block have been projected with especial consideration to the operating conditions and capacities of a gathering and loading machine provided with a swinging conveyor.

The development work connected with the room section here shown has been so planned that within a radius of approximately 100 ft. enough places will be provided to afford a capacity of 125 tons per machine every day, it being assumed that this is the average daily capacity of one mechanical loader.

When the room entries have been driven to their limit and the last pair of rooms extended as shown in Fig. 1, sufficient territory will have been developed so that each room entry will accommodate three loaders per side, or six in all, the rooms being of such width that four of them will furnish work for one loader.

The third step contemplates widening the room by taking three slabbing cuts off one side of each pillar. This operation has been timed so as to form the final stage of the work. It may be started from the inside, that is, on the retreat.

Fig. 1—Developing a Block of Rooms

Heavy lines denote territory developed by loader at the rate of 125 tons per day. This section is now ready for six machines allowing four rooms to each. The total capacity of this group of rooms should be 750 tons per day.

ical loaders and to obtain the entire output of their mines from these machines for periods exceeding a year of continuous operation.

In the Indiana, Kentucky, and Illinois fields it appears that those operations that have made only conservative changes in the mode of mining followed have been more successful than those which made radical departures from proved methods of roof control. However, many enthusiasts hold to the idea that success with loading machines is dependent upon modified longwall mining. At the opposite extreme—and instances of its use are numerous—machines have been placed in the mines with little further preparation for their operation than would have been made had so many more laborers been added to the payroll. Needless to say that in such cases satisfactory results were lacking.

As most of the mechanical loaders installed in Kentucky, Illinois and Indiana during the past year had first to demonstrate sufficient capacity in straight room-and-pillar work to justify their purchase, it is only logical to suppose that more satisfactory results would be obtained by modifying the transportation system than by altering the method of mining. To a certain extent pioneering could thus be made profitable as well as instructive. Only after the capacity of a loader under existing conditions has been determined can the most efficient scheme of transportation be devised.

Installation of improved mining and loading ma-

Fig. 2—Second Step in This Kind of Room Work

Heavy lines indicate mining done on regular room faces. All six loading machines start together and advance all twenty-four rooms at the same rate. The output during this stage should be 750 tons per day.

Fig. 3—Slabbing Finishes the Block

Solid lines indicate territory mined by slabbing. The six loading machines start simultaneously loading out three long slabbing cuts from each pillar. The maximum productive capacity is attained at this stage and the output should approximate 1,500 tons per day.

Up to this time, ample pillars have been left in place to insure against the possible development of a squeeze or creep. The capacity of a loader with a swinging conveyor on slab work is more than double that on ordinary face loading. Where development work is performed on the basis described, it is a weak roof indeed that would not permit of at least three slabbing cuts being taken in the short time required by such a machine to load out the coal produced.

It should be noted that the basic idea embodied in this plan has been to develop sufficient territory so that working places may be provided and the maximum capacity of loaders rendered available as each machine is put into service. The production curve for each stage of operation is, therefore, a straight line. Transportation also is simplified by this plan.

The method, as offered, should be a big improvement over systems now in use in many mines. The intention of the illustrations, however, is to impress on those interested in the operation of loading machines, that the big problem at the present time is that of affording the machines now on the market, the opportunity due them. To this end a planning department should be provided which should have the ability and authority to synchronize the various movements necessary for successful and economical operation of the machine. The plan suggested calls for a loading machine so flexible that it may be used for narrow work, room turning, wide work, and slabbing, for which latter purpose special machines have been designed.

The three accompanying sketches tell their own story. Conditions assumed were: A 6-ft. bed of coal, an average roof, inclination of bed such as will permit of turning rooms off both entries, and the like. In short, the conditions generally found in Indiana and Illinois.

As the first stage, or development work, progresses, a parting should be installed in each extended room neck. This parting should hold sufficient cars to clean up a face of coal. With such an arrangement a mule could be employed to move the individual cars after they were once spotted on the room partings by a locomotive. Where the loading machine is equipped with a swinging conveyor, the rooms may be provided advantageously with double tracks. The machine may thus load alternately first on one and then the other regardless of the position in which it may be working.

The Miner's Torch

What Rock in Coal May Do

THERE are several explanations for pieces of rock being found mixed with the coal which has been shot down at the working faces and ready to load into mine cars. It may have fallen from the roof, it may have originated from partings in the coal, or perhaps the machine mining was made in a soft bottom, etc. Miners do not always separate carefully the rock from the coal before loading the coal into cars at the working face, and the slate inspectors on the top house do not always discover this falling from grace, as it were, on the part of some of the miners. The slate pickers are never able to entirely clean the coal between the mine cars and the railroad cars especially if an inordinate quantity has been loaded by the miners.

Much of the rock that falls from the roof to mingle with the coal falls because some miner takes a chance with a prop; he thinks he may get along without it, and does, but with unsatisfactory results. Much of the rock that is loaded with the coal in violation of the spirit of the dockage rules is loaded because the miner knows that all the cars cannot be inspected and he is willing to take a chance at the penalty. Much of the slate that passes along the picking belt into railroad cars, does so because a slate picker finds it easier to let a piece of rock go by than to summon the effort necessary to lift it off the belt, especially if the boss picker has his back turned.

Some of the railroad cars loaded with dirty coal find their way to railroad coaling stations; a passenger engine coming along just as some of the dirty coal gets to the chute gets a tender full of coal and rock, perhaps mostly rock. Then, as the engine is approaching the maximum grade on the run the fireman finds that he cannot maintain the necessary steam pressure with the coal that he has, and the train gets off schedule. At the next junction point one of the passengers misses his connection, due to the lateness of the train. Many things happen to passengers who miss connections. Some of the consequences are amusing, others are tragic.

Perhaps a railroad car with more than its share of rock is delivered to a retail coal yard. The yard man having paid for the rock decides to pass the bad buy on to his customers. In the course of events some of the coal with rock is unloaded at a hospital coal bin. Firemen at hospitals are just average firemen; they are not able to keep steam pressures up to the maximum with fireboxes full of clinker. There are times when the lives of several patients may hinge on the temperature of the hospital wards. Pneumonia is always just around the corner following operations; an unlooked for drop in the temperature of the room, if not quickly noticed by the nurse in attendance, may mean life or death to such a patient.

Perhaps this impresses you mostly as a journey of the imagination. Your guess is correct; but if the men responsible for the rock that gets to the coal pile with the coal would use their imaginations more, such things would not happen.

Shale Dusting Now Spreading Rapidly in Illinois

Many Companies Follow Lead of "Old Ben"—Traveling Blower to Dust Ribs and Roof Comes Into Use—Valier Coal Co. Tries One-Process Pulverizer to Cut Costs

SOUTHERN Illinois, where are grouped some of the largest bituminous coal mines in the world, is seriously adopting shale dusting. The years of study and thought that have been devoted to the subject of stopping explosions and thus saving life and property by the use of shale dust is getting in its work at last. The mines of the Old Ben Coal Corporation, where the dusting system got its greatest impetus are now merely the center of what has become a widely radiating spread of the dust idea. The Chicago, Wilmington and Franklin Coal Co. at its two great Orient mines, the Peabody Coal Co. at mines 19 and 20, and the Valier Coal Co. at the Valier mine that Carl Scholz built, all are plunging into dusting with definite and comprehensive programs. Others are following. The region is gaseous and the coal dust dangerous. These dangers are to be materially lessened by pulverized shale.

For years the principle of rock-dust protection has been studied in the southern Illinois region, but the events of the last few months seem to have stung the territory into action. Perhaps the fact that in this country the three years 1918, 1919 and 1920 were comparatively free from dust explosions tended to lull Illinois as well as the rest of America into a lackadaisical attitude of mind toward shale dusting.

Only 169 men were killed in major explosions in those years. Much confidence came to be placed in water as a protecting agent against coal-dust ignition. Events of the immediate past, however, have upset this faith in water. The tremendous explosions since Jan. 1 in which nearly 400 lives have been lost and in which coal dust played its part, have helped in this awakening.

Perhaps the recent visit of the official delegation of the British Mines Department, which toured through Illinois, may have helped. Much was said during the tour concerning English rock dusting. Perhaps the studies which George S. Rice of the Bureau of Mines made in England a few months earlier may have added their bit. Naturally the conclusions reached within the year by other Bureau of Mines engineers favoring the use of rock dust in coal mines have had their effect. But Illinois is taking its swing toward rock dust principally because the results of its own investigations

have finally convinced many operators that dusty, gaseous mines *must* be protected with incombustible dust.

Most of the Illinois investigations into the value of dust protection have been made since 1917 and by the Old Ben Coal Corporation under the direction of J. E. Jones, its safety engineer.

It is now generally claimed among mining engineers in the Midwest that Jones has had more experience in rock dusting than any man in this country.

However, the mines of Illinois are not following every detail of the Old Ben plan of dust protection underground. That corporation has applied shale dust in its mines in four ways: In concentrated barriers containing one and a half to three tons of dust, in V-shaped troughs, piled on platforms elevated a few feet from the floor and spread on roof and ribs. It is roof-and-rib dusting which is now being introduced into many of the large mines of southern Illinois.

In order to spread shale dust on roof and ribs throughout the mines, an

old device in shale dusting is now being once more introduced—the traveling blower. For more than a year Mr. Jones and his associates have worked to produce a machine that will do the work satisfactorily. All sorts of devices have been tried in an effort to get something that would distribute rock dust uniformly into every crevice and on top of every projection. Previously dust had been spread by hand with limited success. Eventually a machine was built which is now in its final stages. Its construction details hitherto have not been made public.

Meantime other interested engineers have been busy trying to conceive a traveling blower to serve the same purpose. Their problems have been many. Shale dust pulverized to a fineness of 250-mesh is difficult to handle. Loaded into a hopper feeding into a suction vent pipe, the material persistently packs in the feed line. Its weight, in the case of some Illinois shales, averages between 60 and 75 lb. per cubic foot. Various devices to overcome the difficulties of feed have progressed at least as far as the blueprint stage.

One is equipped with a piston agitator in the bottom of the hopper (Fig. 1). The piston is actuated by a short crank driven by a chain from one of the wheels of the truck so that the speed of the piston is deter-

THE ANTI-EXPLOSION CAMPAIGN IS WINNING

J. E. JONES, shale-dust expert, sees real progress now being made against mine explosions. Speaking of Franklin County and Illinois he says: "The outlook for increased safety against explosions is brighter than ever in the history of the county or the state, as is evidenced by a more thorough understanding of the hazard and the growing interest in the reduction of this hazard by both employer and employee. * * * The three principal factors required to produce a coal-dust explosion are an open light, an accumulation of gas and explosive coal dust. The first is removable by the installation of enclosed lights found permissible by the Bureau of Mines. The second can be minimized by proper ventilation and inspection, but this hazard will always exist in a gaseous mine. The third can be eliminated by neutralizing the coal dust with incombustible dust making a mixture that is non-explosive."

mined by the speed of the truck. This is calculated to feed dust to the blower in a volume varying with the rate of travel. Another is equipped with a belt type of feed to the fan, which also is designed to maintain a given ratio of dust volume to truck speed.

These dust spreaders are to be supplied with flexible nozzles of large diameter. An operator riding with the truck directs the flow of dust according to the immediate conditions. Such a truck, carrying several tons of dust and pulled by a locomotive can proceed at a low rate of speed throughout the entire mine making a uniform deposit of dust on roof and ribs in much less time and at much less cost than ever could have been possible by hand.

Careful studies of the several mines that are adopting stone dusting in Illinois are determining the exact quantities of dust to be applied in each case and are working out frequencies of application calculated to maintain given proportions of incombustible material to coal dust.

It is generally accepted that at least 55 per cent of shale dust must be added to the coal in the roadway to render it harmless. In some cases, higher percentages than this will be provided, running, probably, up to 70 per cent at the time of application. To secure such a proportion, it may be necessary to distribute as much as 10 lb. per lineal foot of 12-ft. haulage or airway or approximately 26 tons per mile. Most of the companies now adopting the dusting method expect to make one thorough and complete dusting of the mine every three months with more frequent application in main haulageways. Periodical dust analyses will determine a frequency of application that will maintain a safe proportion of shale to coal for each mine.

The most definite progress in dusting in southern Illinois, except the extensive work done at the Old Ben mines, has been made at the Valier mine of the Valier Coal Co., owned and operated by the Chicago, Burlington & Quincy Ry. This property, in the northwest edge of the great Franklin County field, has purchased

shale dust for a year from the Old Ben preparation plant, and the Valier men have been spreading it by hand.

Recently the Valier Coal Co. decided to do its own pulverizing, using shale from its own workings. Accordingly it installed a grinder which did not afford the proper fineness. It then set up and is now testing an American ring pulverizer which, for a month, has been producing between one and two tons of pulverized shale per hour, 85 per cent of it is 80-mesh fine and a considerable proportion finer than 200-mesh. One operator at the union top-work day rate of \$6.59 has been running the pulverizer, and the cost of the dust, as computed by the company, is little more than \$1 a ton so long as the pulverizer can get anywhere near continuous running time. This is about one fifth of the previous cost of shale dust to the Valier company.

This ring pulverizer with an air separation system and cyclone collector, as shown in an accompanying

Elevation of a Pulverizing Plant

The cars covered with tarpaulin are run under the bin and receive their load. In this case only one machine is provided, the one unit serving for both crushing and powdering.

illustration, is installed at a point not far from the main shaft. Shale from the mine is hauled by pit car to the pulverizer, broken up into 6-in. chunks by sledges and fed into the hopper by hand by the lone operator. A 40-hp. motor, belt-connected, drives the pulverizer. The fineness of the output of the mill is controlled by opening a bypass valve and closing a deflection gate in the section elbow above the mill. The degree of draft thus created by a 2-hp. motor-driven suction fan determines the fineness of the dust to be delivered through the cyclone collector and discharge pipe into a waiting car lined with tarpaulin.

ALL "OLD BEN" DUST PASSES 150-MESH SCREEN

The only other shale-dust producer in Illinois is the unit operated by the Old Ben corporation. This is a two-stage mill with a capacity of 40 tons of dust per day. Hammer crushers first break the shale into 1-in. cubes and a ball mill equipped with cloth screens and suction fan, grinds the cubes into very fine dust. This plant is at Old Ben No. 9 mine where the shale is considered to be well adapted for the purpose. The percentage of combustible in this shale is low indeed as shown by tests that have been made upon it by the Bureau of Mines. An analysis showed moisture, 1.29 per cent, carbonaceous and other volatile matter, 6.05 per cent, carbon dioxide, 0.48 per cent and ash, 92.18

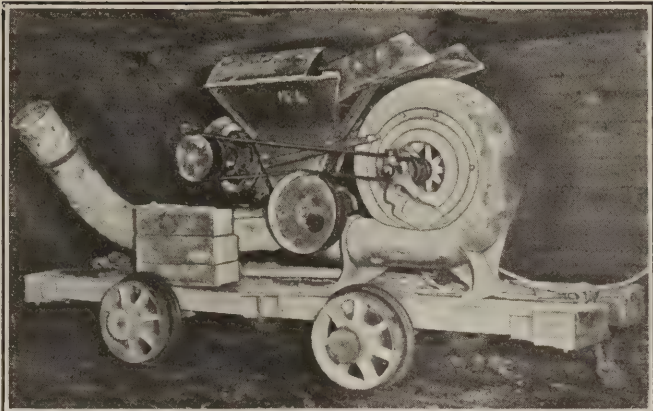

Courtesy American Pulverizer Co.

Pulverizer, Fan and Settling Chamber

The dust as fast as it is pulverized to the right degree is lifted by the draft and drops into the bin. Thus the coarse material is not protected by the fine but suffers all the violence of the pulverizing machinery.

This snail-like machine is rock-dusting roof, ribs and floor of the headings in an Old Ben Mine. The new machine on the same principle will have a double discharge and will completely dust the heading in one trip.

The machine illustrated is operated by two men, treats a heading completely in two operations at the rate of 2,000 to 3,000 lin.ft. per hour distributing 2 to 3 lb. per lineal foot and making the ash content of the mine dust about 65 per cent.

per cent. It comes from the mill all finer than 150 mesh, 97 per cent being 200 mesh and 92 per cent 255 mesh or finer.

Extreme fineness of shale dust for use on roof and ribs is essential in order to get a proper impregnation of the dangerous coal dust deposited there. The removal of such coal dust from mines is a practical impossibility, for the finest of it settles in the most inaccessible places and astonishingly small quantities of it will propagate an explosion. The extent of a dust explosion depends upon the supply of oxygen and not as might be thought, on the quantity of dust. Mr. Jones holds that only 6 or 8 oz. of fine coal dust per lineal foot of passageway is required to satisfy the oxygen per lineal foot, and that therefore, a mine could be exploded over and over again—possibly hundreds of times—merely by refilling it with air after each “blow.” Such facts as these are now realized by engineers in Illinois and elsewhere, and the realization is tending to spread the shale-dust propaganda far and very effectively.

Mr. Jones, in speaking recently before an audience in New York at the meeting of the American Association for Labor Legislation on coal dust explosions and how to prevent them, traced the history of the shale-dust study that has been made in Illinois and described the “Old Ben” system of dusting. He declared that by general and uniform use of closed lights, proper ventilation and inspection of mines and the neutralizing of coal dust with incombustible dust, the dangers of mine explosions will be greatly reduced. The dust hazard, long so troublesome and perplexing, can be removed, he said. In Franklin County, he added, the protection against explosion has been extended to a point where 4,350 of the 12,855 underground men of that county are protected with shale dust and 1,925 with enclosed lights. These figures are expected to be enlarged considerably within the next few months.

A part of Mr. Jones’ paper follows:

Table I—Fatalities From All Causes in Franklin County Coal Mines, 1904-1921		
Cause	Number	Per Cent
Gas and coal-dust explosions.....	203	38.09
Haulage equipment.....	124	23.26
Roof face and rib falls.....	107	20.08
Hoisting and shafts.....	25	4.69
Powder ignition explosions and return to shots.....	22	4.13
Electricity.....	18	3.38
Railroad equipment.....	13	2.44
Falling persons and objects.....	8	1.50
Machinery and mining machines.....	7	1.31
Explosions and suffocation other than by mine gas or powder.....	6	1.12
Total.....	533	100.00

“The Franklin county coal field of Illinois is comparatively new. It was opened in 1904. It now has an annual capacity of nearly twenty million tons. The mines are gaseous, and the coal dust is very explosive. The fatality rate from 1904-1921 was nearly double that of the state for the same period. The difference in the rate was largely due to the fatalities which were the result of mine explosions.

Table II—Gas and Coal-Dust Explosions in Franklin County, 1904-1921			
Cause	Explosions	Fatalities	Per Cent
Gas and coal dust, origin unknown.....	1	51	25.1
Gas and coal dust, naked-light ignition.....	4	99	48.8
Gas, naked-light ignition.....	10	18	8.8
Gas, mine-fire ignition.....	3	32	15.8
Gas, electric arc or naked-light ignition.....	1	1	0.5
Breathing apparatus, after explosion.....	2	2	1.0
Total.....	19	203	100.0
Number of fatalities caused by gas explosions which were propagated by coal dust.....			153
Number of fatalities caused by gas explosions which were slightly or not at all propagated by coal dust.....			50

“The number of fatalities in Franklin county mines from all causes during this eighteen-year period was 533, of which 203 were caused by gas and coal-dust explosions. Table I gives data on fatalities from all causes. Table II shows that three times as many deaths were caused by coal-dust explosions as by gas explosions.

“In Franklin county the progress in preventing explosions has been most encouraging. The chief improvement has been a better understanding of the dangers of gas and a consequent greater respect for it. Formerly, naked lights were often used by fire bosses during their examination, and it was considered a great joke to frighten someone by igniting a pocket of gas. But this is past history in this county. Most of the men employed underground are now aware of the dangers and comply with the regulations made for their safety. One of the chief factors in reducing accidents has been the change from black powder to permissible explosives for blasting.

“How greatly the fatality rate in the county has been lowered from 1904 to 1922 is shown in Table III, in which the first nine-year period of eighteen years is compared with the last nine-year period. The average of the fatality ratings has been reduced to less than one-half those of the first nine-year period.

“On Thanksgiving night, Nov. 29, 1917, the Old Ben Coal Corporation, which now operates nine mines in Franklin county and three mines just across the line in Williamson county, experienced a disastrous gas and coal-dust explosion in Mine No. 11, Christopher, Ill.

Table III—Fatality Rate in Franklin County, Lower Now Than in Previous Decade

Period	Killed	Employed	Killed per 1,000 Employees	Tonnage	Killed per Million Tons
1904 to 1913	156	17,935	8.70	13,965,493	11.17
1913 to 1922	377	88,679	4.25	86,904,726	4.34

This mine is one of the most modern in the United States and was but four years old at the time of the explosion. The mine did not extend at any point any further than 4,000 ft. in any direction from the shaft bottom, and the ventilation was good. The methane content on the main returns has rarely reached 0.2 per cent.

AN OPEN DOOR FILLS HIGH SPOT WITH GAS

"A short circuit of the air current, due to a door being left open at a crosscut 400 ft. from the face of the main east entry, caused an accumulation of gas on top of an abrupt knoll near the face of this entry. This section of the mine was quite wet both inby and outby from this accumulation of gas; the roadways outby being a swamp 300 ft. long which the explosion was compelled to cross before it could extend into any other section of the mine. The percentage of coal dust was exceedingly small in this territory compared with that in the producing sections as the work done was development only.

"As the day was a holiday, only part of the night shift reported for work. Seventeen men were in the mine. One of the men, a pumpman, went to the main east entry to start an electric pump to remove the water from that section preparatory for the next day's work. His carbide naked light ignited the gas.

"The ensuing explosion dried the saturated coal dust in its immediate vicinity to such an extent that an explosion was propagated with intense violence and heat throughout the entire workings, wrecking the mine in every direction, especially close to and in both shafts, instantly killing all the men.

"Had this explosion occurred on the day shift with its 600 men underground, every man would have been killed, and Franklin county would have had the worst mining disaster, if not the worst industrial disaster, of the United States.

"Considering the large volume of air, the apparent absence of coal dust and the wet condition of the territory where this explosion originated, one can easily understand that a dust explosion is always imminent in a gassy mine and that it is futile to hope to prevent the propagation of an explosion by cleaning or sprinkling the mine workings.

"This experience caused the officials of the Old Ben Coal Corporation to lose the little faith they might have had in the theory of watering and cleaning to prevent coal-dust explosions.

"The explosion also forcibly impressed them as to the hazard of naked lights, especially in a gaseous mine where the forgetfulness of one out of 600 employees might result in leaving a door open for considerable length of time or cause other derangement of the ventilation, permitting the accumulation of the explosive gas or the entrance of a miner with a naked light into a forbidden and gassy place.

"D. W. Buchanan, president of the company, decided from that time on to use enclosed lights and shale dust. When the mine where the explosion occurred resumed operations, it was on a strictly enclosed-light basis.

This, however, was following a three months' strike by the miners against the enclosed lights. The company now has three mines in which only enclosed lights are allowed to enter night or day. In the other mines enclosed lights are used to the exclusion of all others from the quitting time of the day shift until starting time the following morning.

"The methods of preparing and placing shale dust were given much study. From a representative mine of the company samples of dust and air were collected by a Bureau of Mines engineer and these samples were sized and analyzed by the Bureau of Mines.

"Voluminous analyses showed that the most dangerous dust is laid along aircourses, at the working faces and on the roof and ribs of haulage roads and that the dust along the floor of the haulage roads is generally so high in ash that it is not nearly so hazardous as the other accumulations of coal dust.

"Five tons of coal were also sent to the Bureau of

One pair of wheels keeps the dust in the hopper loose so that the fan can draw in the dust and expel it.

Mines' experimental mine from this representative mine to be ground into dust and subjected to experiment to determine its explosive properties. A commission of mining men from the state of Illinois and the Old Ben Coal Corporation were present at the Bureau's mine during part of the experiments. These tests showed in part, that Franklin county mine dust, containing 42.82 per cent of incombustible matter with no gas present, actually propagated an explosion, and that mine dust containing 58.66 per cent of incombustible matter with no gas present did not propagate an explosion.

The test also showed that dust containing 58.17 per cent of incombustible matter with 1.1 per cent methane present and dust containing 66.72 per cent incombustible matter with 2.2 per cent methane present both propagated explosions. It was demonstrated also in the experimental mine that the flame of an explosion could be successfully extinguished by rock dust that had been placed in Taffanel and concentrated barriers.

"The first problem in the rock dusting of the mines was to find material that would make an acceptable dust. Limestone dust was purchased, but this was found to be too coarse and to contain too much siliceous material. Surface road dust was also tried but it was found that a small quantity of moisture would cause this dust to cake and cease to act as a dust. The shale overlying the coal seam was analyzed and found to be exceptionally suitable for the purpose, hence the name, shale dust.

"Old Ben Mine No. 9 was chosen as the logical mine from which to obtain the shale and prepare the dust because of the cage-equipped material shaft and the adequate railroad connections for the field. A mill for the grinding of the shale into dust is installed at this mine. It has a maximum capacity of 40 tons of dust per day.

“Early in the mining experience of the county it was learned that the panel system of mining was that most favored for the localizing of explosions and mine fires. The panel system, where the panels are not connected to each other, gives a unit system of mining whereby each unit or panel is a territory by itself with unbroken coal pillars between it and all other units or panels, the only openings being those where the two entries connect with a pair of main headings for ventilation and haulage. The distance from one pair of panel openings to another pair is usually 500 ft.

“As the purpose of the shale-dust installation is to localize explosions, these two entries are the most important ones in which to install dust. An explosion cannot get into or out of a panel without passing through one of these two openings. Therefore, the shale dust is installed from the first room on each panel back to the entries from which the panel is turned and along these entries for 100 ft. in each direction, the trackless passages being provided with shale-dust troughs and the haulage roads having the roof and side walls coated with the shale dust. In addition to this protection each set of panels is protected by an ‘Old Ben’ concentrated barrier.

“Possibly of no less importance is the protection of all haulage roads and aircourses. Haulage roads are protected with the concentrated barrier at intervals of 500 ft. or less, the aircourse opposite the barrier having the trough installation. In addition to this protection the shale dust is now being mechanically applied by small portable high-speed fans to the roof and side walls of all the haulage entries and is being blown into aircourses to be carried into the mine and deposited, all

this giving a high incombustible content from the shaft bottom to Room No. 1 of each panel.”

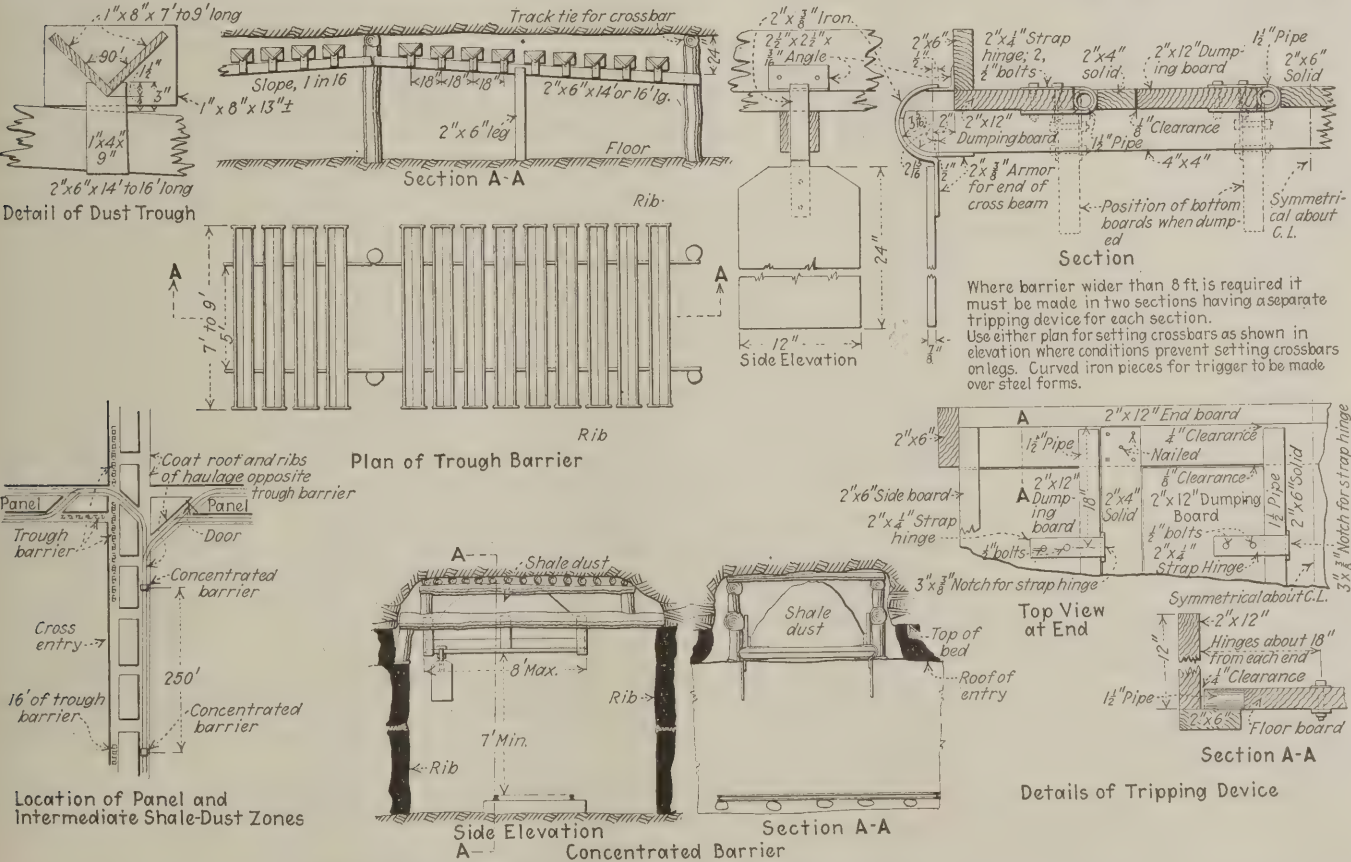

Mr. Jones in his address also described the “Old Ben” concentrated barrier, the V-shaped shale trough, the shale platform, and the distribution of dust on roof and ribs as follows:

“OLD BEN” CONCENTRATED BARRIER

“The ‘Old Ben’ concentrated barrier has been designed with two purposes in view: (1) Placing in suspension a large quantity of the shale dust in as simple a manner as possible by the action of an explosive force, and (2) making certain that even though the device should be tripped accidentally or mischievously no part of it would fall a sufficient distance to injure a person who might be under it or endanger those on moving trips while approaching or passing under a barrier.

The barriers are built in roof cavities dug for that purpose and hold from one and one-half to three tons of dust. The bottom of the barrier is usually approximately in the same plane as the roof. The bottom, or floor, of the barrier is made of several, usually four to six, 2x12-in. or 2x14-in. planks, each plank being approximately 6 ft. long, dependent upon the width of the barrier.

Each of these planks is hinged on one edge, this hinged edge resting on the sides of the barrier. When free to move, the width of the plank hangs vertically. The floor, when the barrier is ready to be filled, is in a horizontal plane, the free-moving edge of all the planks being held in place by a beam which rests on two trigger vanes. Each of these vanes may be tripped from either direction, the displacing of either vane

Devices Used by Old Ben to Rain Powdered Rock on a Coal-Dust Flame

The troughs are used on roads that have no tracks. Concentrated barriers are installed on main haulageways. These latter are upset whenever the blast from either direction strikes a projecting vane. The dust in the troughs is not spoiled by mois-

ture as readily as that in the roadways and is always ready for action. Besides its location above the roadway makes its distribution at the right time more certain and more intense. Prompt and positive release is secured by vane triggers.

causing the floor of the barrier to swing down about 10 in. and permitting the dust to flow down through the openings thus made in the floor. The flow of dust continues for ten to twenty seconds and gives a dense dust screen over the entire cross-sections of the passageway.

DUST TROUGHS UPSET WHEN BLAST OCCURS

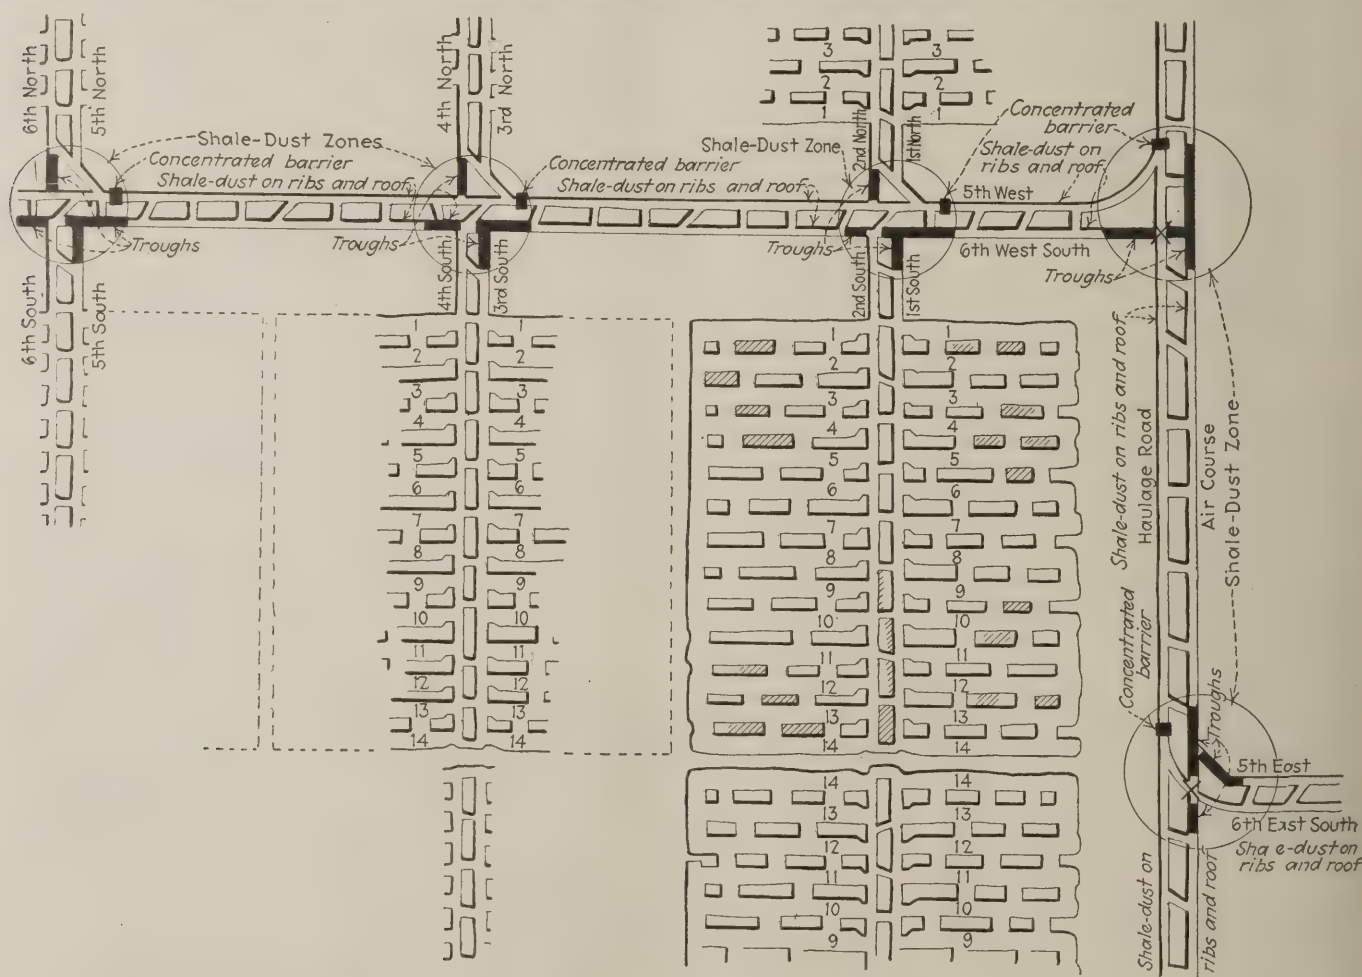

The shale-dust trough is V-shaped and made from 1x8-in. lumber. It is from 5 to 8 ft. long, the length being dependent upon the width of the passageway. The troughs are filled with the dust, from 50 to 80 lb. being placed in each. They rest on two small notched pieces of wood which have been nailed to framework. The troughs are placed close to the roof yet have sufficient clearance to that a slight explosive force will upset them and discharge the dust.

A violent explosion would, of course, tear out the entire installation but with a slight force the trough will turn part way over in the direction of the force, retaining about one-third of its dust to be thrown in the opposite direction should a reaction of the explosion occur. As the troughs are installed close to the roof an explosion causes a dense dust screen to be formed in the entire cross-section of the passage way. Placed in this position they give the least obstruction to ventilation and to the travel of persons. Wherever concentrated barriers are installed on the haulage road shale-dust troughs are installed in all trackless passages

of adjacent parallel entries to give a complete barricade of shale dust.

"On haulage roads in the shale-dust zones the dust has been thrown on the roof and ribs by hand, a large percentage of it falling to the floor. Because of the extreme fineness of the dust a large part of it is carried along the entry by the air current, settling on timbers, ribs, roof and bottom for long distances from where it is being spread. Recently the dust has been distributed successfully by small high-speed portable fans, the dust being fed into the intake of the fan and conducted by a hose of large diameter. By this means the dust has been deposited at any point desired. This method is so efficient and its cost so light that it bids fair to offset the necessity for the large number of concentrated barriers now in use in each mine.

Elevated platforms are usually made from broken and discarded ventilation doors and stand from 2 to 4 ft. above the floor. The principal purpose of these platforms is to supply additional shale dust in the event of an explosion and the secondary purpose is to give a supply of dust for refilling of troughs. When shale dust is stored on the mine floor much of it is wasted because the dust absorbs moisture from the fireclay and becomes mud, or is trampled into a solid mass that would prevent it from being thrown into suspension. The closer to the roof the dust is stored the greater the possibility that it will be thrown into suspension quickly in the event of an explosion."

How Old Ben Lays Out Mine in Panels and Guards Portals with Shale Dust Zones, Concentrated Barriers and Dust Troughs

The mouth of each panel is regarded as a point at which an explosion if generated must be stopped or it will involve other headings. Consequently it is arranged that if the flame of the explosion tries to leave by either main or back entry it will be promptly extinguished by a deluge of dust.

How to Get Big Output From Loading Machines

Plans That Enable Loaders to Keep Working Steadily but Which Do Not Involve Radical Reconstruction of Mine Workings or Abandonment of Room-and-Pillar Methods

BY WALTER M. DAKE

Consulting Engineer,
Franklin, Pa.

BY THE use of mechanical loaders the labor expense of producing a ton of coal, now averaging about 70 per cent of the whole cost of production, may be cut down to such a degree as to lower the cost of the coal delivered on the railroad car under the tippie by as much as 40 to 50 per cent.

The advantages inherent in the use of mechanical loaders may be briefly summarized as follows: An increased tonnage per man per day; an increase in efficiency throughout the entire operation of mining as the result of a concentration of workings; an increased speed in undercutting because of a more definite cycle of operations; an increased tonnage per pound of explosives used; a decrease in haulage costs because of concentration of mining operations; a decrease in the quantity of timber used because the work progresses rapidly; a decrease in the cost of ventilation and drainage made possible by a reduction in the number of working places; an increased extraction of coal resulting from the more rapid advance of the work; a reduction in overhead expense rendered possible by a more uniform daily output and a decrease in the number of accidents sustained due to better supervision made possible by a concentration of working areas, which in turn results in lower insurance rates.

AN ANALYSIS OF CONDITIONS IS NECESSARY

Having decided to use these machines a careful analysis of the physical conditions in coal bed and workings should be made, for here, as in other industries, any improvement in methods or apparatus inevitably requires such modifications and changes as will enable the new device to function at maximum efficiency. This does not imply any drastic departure from methods proved suitable for hand loading. On the contrary, it would not be advisable to reconstruct the mine, for a settled policy can be reached only after long and careful study of local operating conditions. However, inasmuch as the change from old to new methods is made for the purpose of accomplishing certain specific results, so far as possible conditions should be modified to suit the new arrangement.

Attainment of steady production is largely dependent upon the adaptation of the machine to each particular problem. This application must necessarily be evolved by the operating personnel of each property. Realizing how greatly working conditions vary throughout the coal-producing fields and the impossibility of formulating any set rule of operations applicable to all districts, the following fundamental suggestions covering mechanical loading are offered.

The generally accepted plan of coal development throughout the United States is some form of double-entry room-and-pillar system. Although this plan is employed in approximately 98 per cent of the producing mines of the country, the variations and modifications

introduced are innumerable. As longwall mining was originated for use in thin beds, it has not been necessary to apply it in this country, except in a few instances.

The simple room-and-pillar system, either in panels or otherwise, and either advancing or retreating, together with hundreds of variations employed for recovering the pillars is well adapted to the extraction of coal so long as such a comparatively slow method as hand loading is adopted. Mechanical loading makes it possible to increase greatly the speed of mining. A modification of the present methods, without drastic departure from the general plan, will meet the physical conditions encountered, while at the same time it allows the machine to operate at maximum efficiency.

Underground transportation is an important factor in the cost of coal. Without proper equipment, coal cannot be economically gathered and delivered to the surface. Similarly, without proper track arrangements the time lost in car shifting may readily absorb the entire margin of profit. Consequently a few suggestions concerning track maintenance and equipment with particular reference to their relation to mechanical loading will not be inappropriate. Favorable grades and a firm, well drained track are primary requisites of any economical haulage system. Rail of adequate weight to carry the expected load should be permanently laid on all main haulways. It is false economy, regardless of its first cost, to install a rail too light to carry the maximum load. Although local conditions govern the gage of mine tracks, it is well known that the wider the gage the greater will be the stability of the rolling stock. In order to avoid derailments and other accidents, the track should be constantly maintained to gage and in alignment.

Tie sizes are governed by rail weights and track gage. Ties should be selected, however, to give the minimum maintenance cost. For track that must be

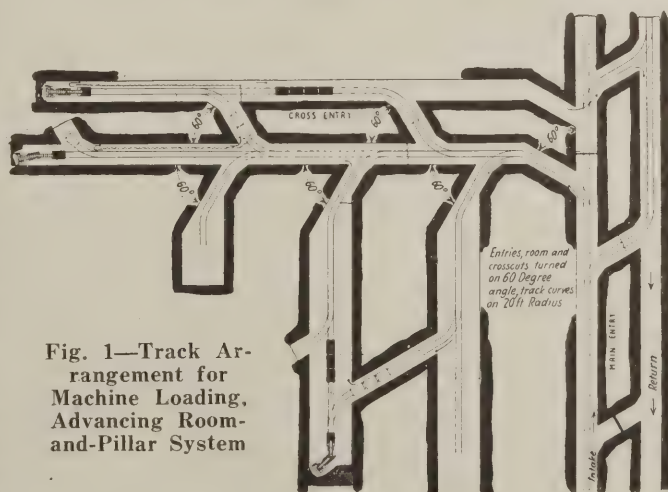

Fig. 1—Track Arrangement for Machine Loading, Advancing Room-and-Pillar System

Fig. 2—Trackage System for an Advancing Machine-Loading Panel

This shows how the tracks may be utilized to afford storage for both empty and loaded mine cars. All cross cuts and rooms are turned at a 60 deg. angle.

frequently moved, steel ties should be employed. The additional headroom afforded by their use and the ease with which sections of such track may be moved or replaced well warrants the first cost of this equipment. Track curves should be laid on standard radii. To promote smooth transportation, as well as for easy movement of loading machines, the radii of curves should be more ample than are usually found in average practice. Adoption of a standard curve with a minimum radius of 20 ft. will be beneficial.

Switches, frogs, guards and curved rails in general should be standardized, and whether made up in the shops or purchased, should be delivered underground ready to put in place. Where electric haulage is used, the track should be carefully bonded. Trolley-wire supports and insulators should be standardized, thus reducing power losses. Local conditions dictate the size of mine cars that may be used. As a general rule, however, the initial investment necessary for a large size of car is more than compensated by lower cost of maintenance and an increase in the tonnage movement. The possibility of reducing frictional losses by the utilization of anti-friction bearings is well recognized throughout the industry. The weight, size and type of locomotives to be used is governed by local conditions, gradients, size of trips and length of haul. All rolling stock, but particularly locomotives, should be systematically inspected and repaired.

LITTLE CHANGES THAT MAKE LOADING EASY

So much for the general principles of mining and transportation. An analysis of a few arrangements and systems that have proved successful with machine loading will now be attempted. In Fig. 1 is shown the plan of a mine section during the early stages of development. All cross-entries, room necks and crosscuts are shown turned on angles of 60 deg. This promotes the easy loading of coal from room necks and crosscuts, facilitates the laying of curves on a minimum radius of 20 ft., and permits the easy starting of heavy trips. All points on chain pillars and room necks near track curves are slabbed sufficiently to allow clearance.

The advancing, main and back entries are shown connected by crosscuts at a point near the main cross entry thus forming a local empty and loaded storage track. A run-around is also utilized in the advancing

entries to provide similar storage. The same system is followed in driving rooms by placing track in room crosscuts. In narrow work in the room-and-pillar system the tonnage output per loading machine increases inversely with the time lost in changing cars; that is, it decreases as the distance from the nearest siding is lessened.

Fig. 2 shows a suggested track arrangement designed for machine loading, and the manner in which these tracks may be utilized for mine-car storage. In this plan, all room necks and crosscuts in the panel are turned on angles of 60 deg., and all track curves are of 20-ft. radius. Four rooms are shown with crosscut track connections designed so as to permit the greatest flexibility in transportation facilities.

CROSSCUT TRACK MOVED AS WORK ADVANCES

As rooms are advanced and crosscuts connected, the track is removed from the last crosscut and replaced in the new one. This provides car storage at a point close to machine operation. A double-track arrangement so designed as to be easily removable and of sufficient length to clear one car on each track may be used in wide entry and room work to provide a car storage at the machine.

This section of track should be rigidly constructed so that by attaching a chain to it and to the loading machine the entire "Y" may be moved forward in the room or entry by the machine. In order to advance this section as required, temporary rails are joined to the permanent track on one end and to the "Y"-section on the other by means of quick-acting clamps designed for this purpose. A detail of these clamps is also shown in this figure. By the use of this simple track arrangement the time necessary for changing cars at the machine can be materially reduced.

Fig. 3 shows a suggested modified retreating panel-and-wall system of mining for use with loading machines. In mining a block of coal containing, say, 40 acres, the thickness of the cover, the condition of the floor and roof, as well as the character of the coal itself, may demand extraction by some method that will allow one-third to be taken on the advance and two-thirds on the retreat. Rooms may be driven on 72-ft. centers with a width of 24 ft. and pillars then pulled; or, rooms may be driven to their limit on 72-ft. centers with a width of 12 ft., two slabbing cuts taken for the entire length of each room, and pillaring operations then commenced. In either case the weight per square foot remains the same at the completion of first extraction.

However, when the roadways are driven only 12 ft. wide, they are no longer like rooms but more closely resemble single entries. In many mines they need no timber and when they are completed the rib on one side can be treated as a longwall face, thus permitting the mechanical loader to be operated for the entire length of the room. In consequence, it can handle a large tonnage, and the transportation units are enabled to work under the most favorable conditions. The same principle can be applied to mines where, owing to squeezes and creeps, it has not been found possible to draw the pillars satisfactorily. The pillars can be slabbed till a crushing strain develops. The rest of the pillar can be left. In this instance, however, the distance between room centers may be increased, the original room widths may be narrowed and a number of slabbing cuts may be

taken throughout the entire length of the panel before abandonment is necessary.

This application is shown in detail in Fig. 3, as a modified retreating panel of any length and width, developed from double main and cross entries. All narrow work is turned on angles of 60 deg. and the minimum radius of the track curves is 20 ft.

Ventilation as indicated in this plan consists of a separate split for each panel. This is taken from the intake through the main cross entries and through rooms, where regulators may be installed. The air is next conducted through the back cross entry to the main return which is overcast at cross-entry intersections. In driving the narrow rooms through the panel before connections are made, portable blowers and flexible tubing may be utilized to furnish air to the faces.

Narrow rooms, Nos. 1, 2, 3 and 4, are shown developing. This work is prosecuted from the cross entry which has a parting of adequate length to accommodate narrow-work switching. These rooms, however, are driven of sufficient width to permit a movable double-track "Y" to be used at the machine as shown in Fig. 2. Room No. 5 is shown connected through and with the first wall cut practically cleaned up. A loader with gathering head parallel to the cut delivers coal to a large trip of cars, while the mining machine is making its second cut on that portion of the wall that has been uncovered by the loader.

Room No. 6 shows the second wall, or slabbing cut, being loaded out and the third wall cut being prepared for drilling and shooting. Room No. 7 is operating on the sixth cut. Solid lines indicate the present position

of the track, and dotted lines indicate its former positions. As shown, the tracks are moved over toward the rib after each two slabs have been loaded out.

SLABBING CUTS FACILITATE RAPID LOADING

It is easy to see how this method facilitates the problem of transportation. At each cut empty cars are loaded in a continuous trip without any delay. They are hauled out on one side of the panel, and a second trip is brought in from the other side. The delay between trips, however, is insignificant, for the second trip may be standing ready to replace that which has been loaded.

A continuous movement of empty cars past the faces can be arranged in operations of this character. By this means the time lost in car or trip changing may be reduced to a minimum. That the reader may be enabled to compare the tonnages ordinarily obtained by hand methods with those obtained by this system, it may be said that where 6-ft. cuts were made in 6-ft. coal 800 tons were loaded by machine in a single eight-hour shift. Where a system of this kind is applied to operations where the total extraction of the coal is not customary, an uninterrupted car movement can be obtained. In such cases the coal can be mined at an extremely low cost.

Fig. 4 shows a room-and-pillar method suitable to the operation of loading machines, the rooms and the pillars both being worked advancing. This system is suited to thick beds such as are found in the West. The section of mine to be operated in this manner is developed by main and back entries which are used as intake and return aircourses respectively.

Fig. 3—Retreating Panel in Which the Loading Machines Operate Along the Side Walls of the Rooms

From these are turned pairs of right and left cross entries carrying air splits. All cross entries, room necks and room crosscuts are turned at 60 deg., and the track curves are laid to standard radii. From the main cross entry, rooms are driven to their limit on centers the distance between which is determined by local conditions. Room tracks are connected through the crosscuts nearest the working faces giving maximum flexibility of transportation.

A loading machine is shown in operation in the last crosscut of room No. 6, utilizing for the storage of empty cars that portion of track extending past this crosscut. The track laid in the nearest crosscut outby forms a storage place for loaded cars. Another loader is shown operating in the face of Room No. 5, using the last crosscut for empty storage and the one nearest to it for loaded cars. In both instances, incoming empty trips as well as outgoing loads, can be delivered to, or pulled from, the storage tracks by the main-haulage locomotives. The cars can be changed at the loading machine by a lighter switching locomotive.

As the distance to be covered in shifting both loaded and empty cars is reduced, the mechanical loader can deliver a maximum tonnage per room per minute. Where the condition of the roof is unfavorable, the distance between room crosscuts should be made such that pillars may be drawn by the usual method of cutting a crosscut near the end of the room pillar and then reducing the small detached pillar thus formed by cutting toward the inby edge of that pillar until it is reduced to the required thickness. The stump thus formed may be

either left standing or drawn by hand. The pillar ends may be arranged to conform to the usual saw-tooth fracture line. However, with favorable roof and floor conditions the plan shown probably will give satisfactory results.

When the first room has been completed and the last crosscut in it has been driven, slab cuts successively may be taken beyond the room and crosscut into the barrier pillar protecting the next cross entry till the pillar has been reduced enough to bring it to the thickness required. An example of this method of removing the first portion of the pillar is shown between rooms No. 4 and 5.

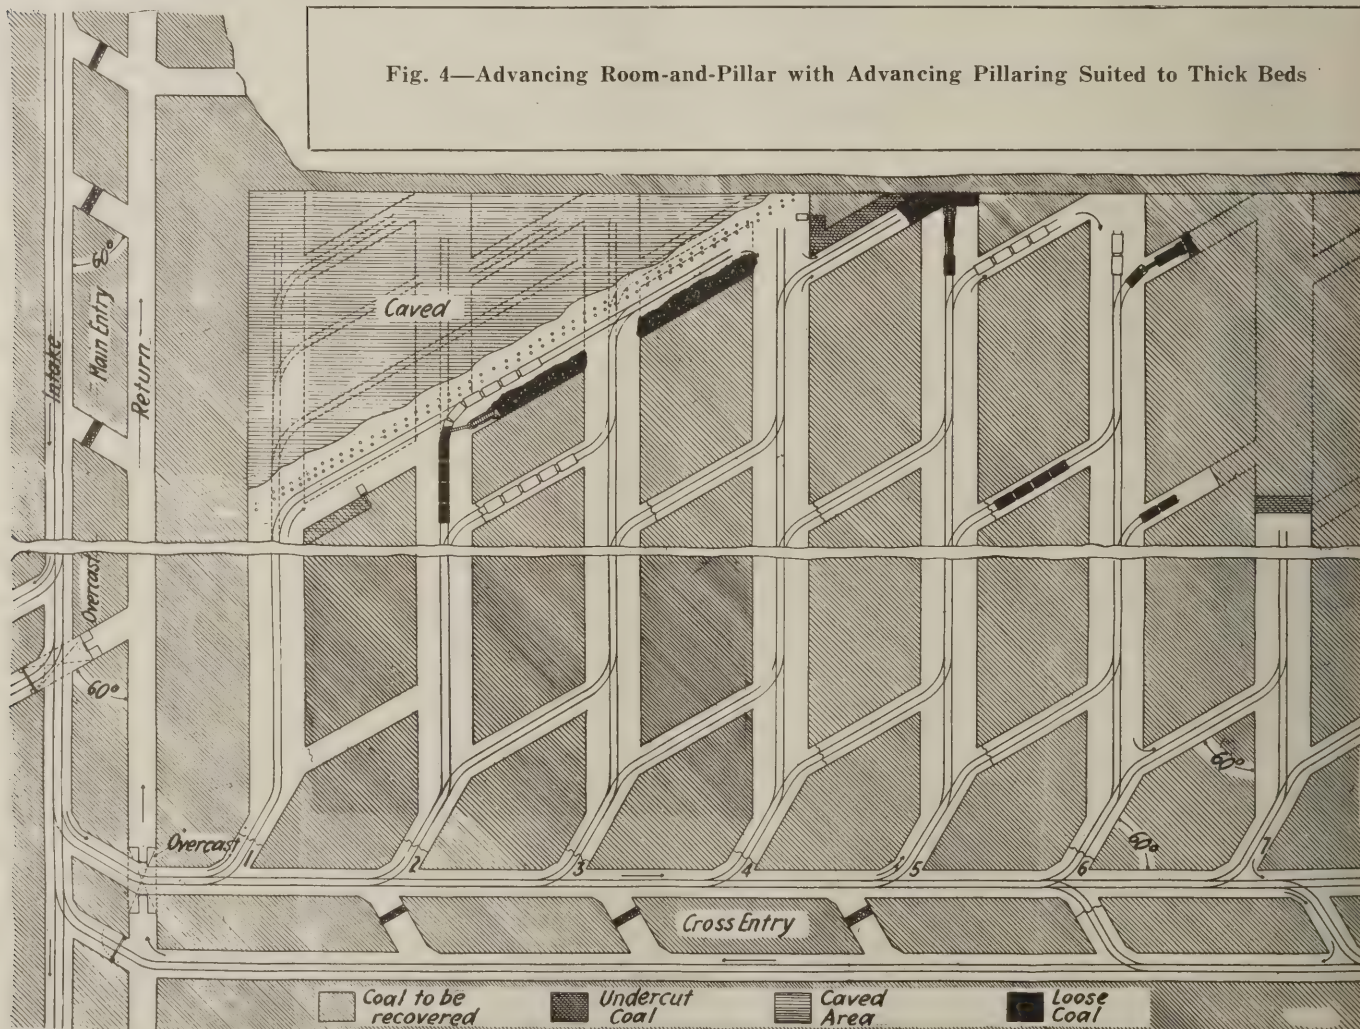

When pillaring has been started in the manner just described, the undercutters take slabbing cuts on the retreating side of the last crosscut until a sufficient area has been extracted to permit of caving the roof. Both cutting and loading machines may be protected by a break line of props wherever local conditions demand such protection.

CONTINUOUS BREAK LINE MAY BE ESTABLISHED

Loading tracks are moved forward after every second retreating cut. New props are then set, and the old break-line props pulled. After a sufficient distance has been gained, a break line, presenting in effect a continuous face of pillar cuts, may be established.

By this means the undercutters are afforded cuts two or three times longer than in room faces. By properly arranging the cycles of operation the work may be performed with maximum efficiency, as little time is lost in

Fig. 4—Advancing Room-and-Pillar with Advancing Pillaring Suited to Thick Beds

moving from face to face. The mechanical loader operating with its gathering head parallel to the cut, moves into position at one end of the face and continues loading throughout the entire length of the cut. Connecting the face track with the room track will allow the loader to fill an entire trip without interruption. As the time consumed in changing trips should not be materially greater than that employed in changing single cars, it is obvious that the total operating time of the machine will be greatly increased.

Though this method of operation is based primarily on the standard room-and-pillar system of mining by the introduction of a slight variation from usual custom, a condition is secured that meets the physical characteristics of the deposit and at the same time allows the loading machine to operate at maximum efficiency.

Fig. 5 shows a suggestion for a retreating panel system of mining, adapted to machine loading. Development is made from headings by single entries driven at an angle. This plan is suited to transportation from the faces by either cars or conveyors. This system may be adopted with any standard or modified entry system of development. The size and shape of panel, and the angle at which the single entries are turned are governed by local conditions.

In this plan is shown a double main and cross entry for haulage and ventilation. With the exception of the single entry developments off the cross heading, which are turned at 45 deg., all openings are turned at an angle of 60 deg., and all track curves are laid on radii at 20 ft. Here again the main and back cross head-

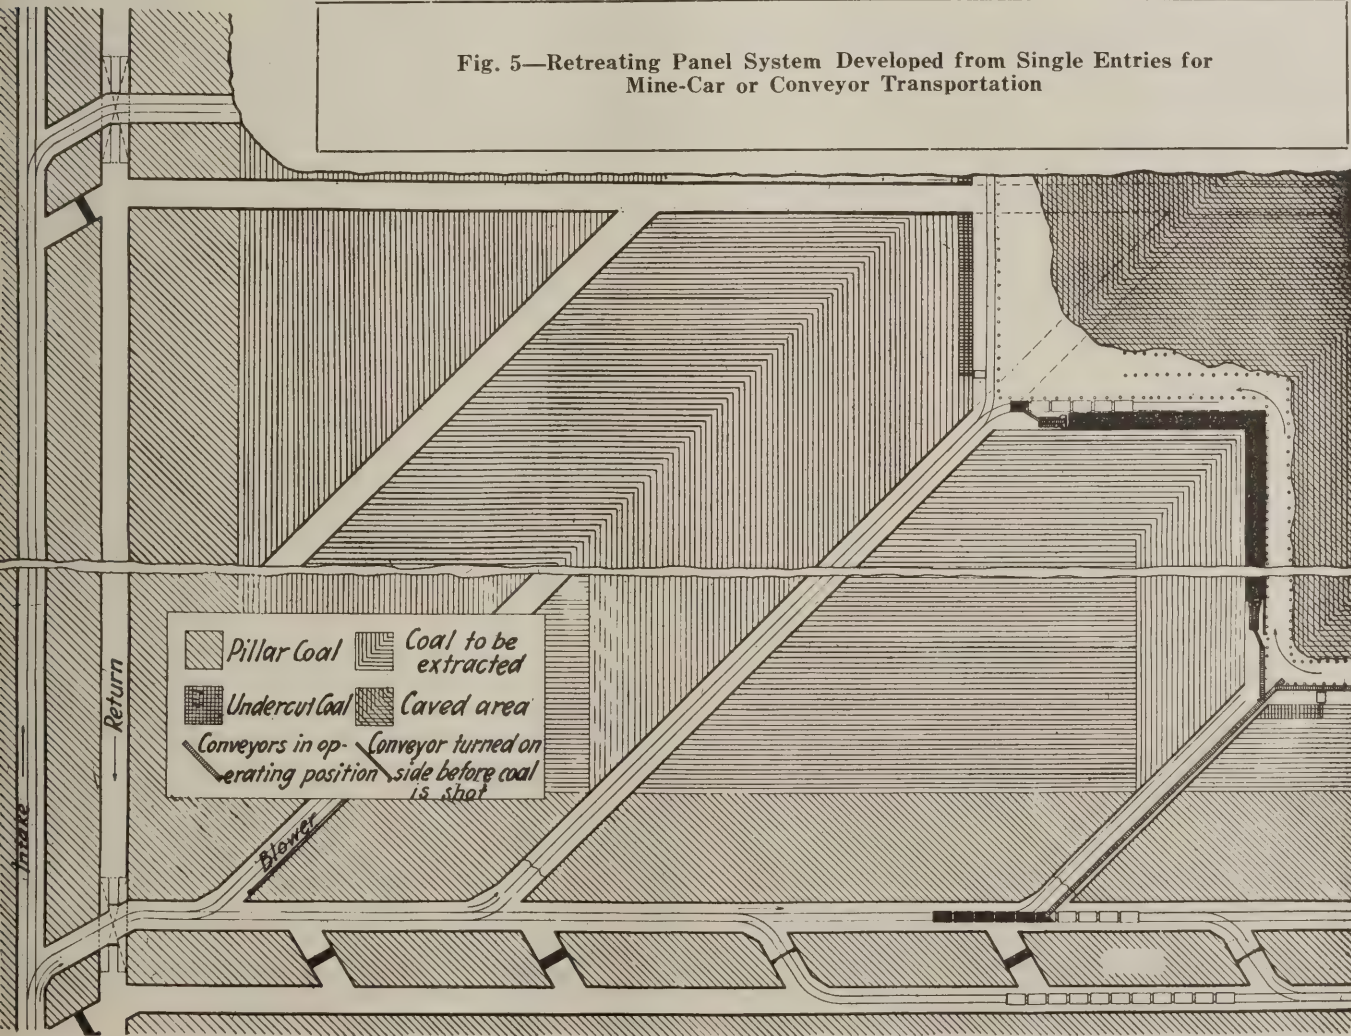

ings are shown connected through the crosscuts by a track arrangement that forms loaded and empty storage.

The entries are driven on such centers as to afford the greatest possible length of retreating face allowable under local working conditions. These entries are driven of sufficient width to permit of the use of the two-car, double-track "Y." Ventilation is supplied by portable blowers placed at the main cross heading, which supply air to the face through tubing or ventilating pipe.

When the single entries have been driven through to the panel boundary, cuts are taken on each side of the connection, to give the angle at which faces are to be carried during retreat. The method of timbering and spacing of props at the faces, together with the system of caving and the maintenance of the break-line, may be determined according to local operating conditions. In this instance single entries are shown turned on an angle of 45 deg. from the main heading on approximately 166-ft. centers; or, at points in the main heading about 260 ft. apart. This gives a pillar thickness of 154-ft. Retreating faces are shown at an angle of 45 degrees to the angled entry, or 90 deg. to the main- and cross-entry development.

SAW-TOOTH PILLAR POINT YIELDS BIG TONNAGE

Maintaining the saw-tooth arrangement on an angle of 45 deg. from the single entry, gives a 100-ft. face on each side of the retreating block. At this angle, faces aggregating 200-ft. in length are obtained from a block 166 ft. wide. Assuming that one full cut 6 ft. deep

Fig. 6—Panel Developed by Modified V-System

This plan is adapted not only to loading machines but to either mine-car or conveyor haulage. High-output, low-cost mines in the future will doubtless use conveyors.

is made on each face per day, in a 6-ft. bed, the block would produce 266 tons. This operating concentration, made possible by a slight variation from the practice customary in panel work, greatly increases the speed with which the coal is extracted and enables the mine to be operated efficiently. Although this system has been advocated recently as a means of transporting coal from the faces by conveyors, it is well adapted, where physical conditions will permit, to mine-car haulage.

Fig. 5 shows a single entry with its tributary faces operated by mine-car haulage and another operated by face conveyors with a main conveyor extending to the heading where the coal is discharged into trips of cars. In both cases mechanical loaders are shown operating with their gathering heads parallel to the cut, and their discharge conveyors filling a trip of mine cars in one case and delivering coal to a face conveyor in the other. By the use of large trips the time of changing is materially decreased. When a sufficient length of track is not available at the face, or when the necessity for timbering will not permit the width necessary for track and car clearance, conveyors provide continuous transportation to headings where uninterrupted trip loading may be effected. By the adoption of this method to retreating panel work the loader is given an opportunity to accomplish the results for which it was designed.

Fig. 6 shows a suggested modified panel, "V"-system adapted to machine loading and to transportation from faces by either cars or conveyors. This is a further modification of the retreating-type panel, and was recently presented to the coal industry as particularly applicable to conveyor haulage. Its advantages, however, may be realized also when mine cars are used and it is well adapted to machine loading.

As in Fig. 5 the size and shape of the panel, and the angle at which retreating faces are carried, should be governed by local conditions. As here shown the V-system is developed from double main and cross entries. Main and back cross entries are connected through crosscuts by an arrangement of track affording storage for both empties and loads. Single entries are driven on such centers as will give the desired width of block, and length of angle face. Ventilation is supplied to single entries by small blowers.

Upon completion of single entries through the first section of the panel, angle cuts are taken on each side and face operations commenced. As noted in the explanation of Fig. 5, all detailed methods of operation

such as timbering, caving, establishing a break-line, etc., can be adapted from local practice.

The V-system, as illustrated in Fig. 6, is operating on 60-deg. pillar points, giving 120-ft. faces at an angle of 30-deg. to the single entries, which are driven on 132-ft. centers. This gives a double face, each face being 120 ft. long, for a 120-ft. pillar width. Thus the length of the angle face is twice as great as that of a straight face across the same pillar. One 6-ft. cut per day, in coal 6 ft. thick, will yield 160 tons per face, or 320 tons per section.

In Fig. 6, section 1 shows in detail the method of operation for mine-car transportation. The trackage arrangement is shown in solid lines for its present location, and broken lines indicate its former position. This particular section is shown with the track moving forward upon completion of two face cuts. This distance will, however, depend upon roof conditions.

LOWEST COST CAN BE ATTAINED WITH CONVEYORS

Section 2 shows how the cutting machine is operated. Portions of the track are in this case moved up after each cut. Section 4 is designed for complete conveyor transportation, and shows a cutting machine operating on one side and a mechanical loader on the other. Entries bounding this section are equipped with conveyors from angle faces to main entry, where mine-car trips are loaded. It is not unreasonable to expect the large-tonnage, low-cost mines of the future to be completely equipped with conveyors.

Face conveyors are shown built in sections. These may be turned on edge with their bottom plates toward the cut and the flight-face against the props before shots are fired. This is done to reduce the roof span in tender sections to a minimum, as only 8 ft. is needed between props and the new face to allow clearance for conveyors serving loading machines. The clearance between props and loading faces, in all operations where mechanical loading is employed, may be materially increased on account of the speed with which faces move forward.

This progress will result in an increased extraction from any given area, and allow a temporary increase of the roof span needed. As coal is loaded from the space between the conveyor sections and the face, each succeeding section as it is uncovered is turned to running position, and the tonnage continually delivered from the machines as they advance. The sequence of cutting and loading in each section of a panel of this character, may be so arranged that as a cut is taken the face drilled and shot on one side, the mechanical loader can be cleaning up the coal on the other. This can be made possible by a concentration of ventilation, provided state laws do not prohibit such practice. The tonnage delivered to the haulage locomotive or to the conveyor on any entry can thus be kept fairly constant.

No great departure has been made from accepted principles of panel mining in the systems outlined, but the opportunity for a record performance of loading machines has been increased many-fold. The outstanding features embodied in the illustrations are so elementary as to require no further emphasis or repetition. Mining men are daily attacking and solving problems far more difficult than any proposed in this article. In fact the practical application of mechanical loaders to coal production is simply a modification of present methods for the purpose of making available the large capacity of these new mechanical units.

News Of the Industry

Sees Co-operative Marketing of Coal as Relief from Cutthroat Competition

Merger Trend Believed to Foreshadow Further Move to Avert Recurrence of Distressing Conditions of 1914—Initiative Left to the Industry—Association Control Now a Pressing Problem.

BY PAUL WOOTON

Washington Correspondent of *Coal Age*

Along with the consideration of co-operative marketing as applied to agriculture, legislators and executive officials have given some thought to its extension to other industries. Many believe it is thoroughly practical to apply the principle to coal. It has been resorted to with great success in Germany and has come in for serious consideration in the past in this country.

There is reason to believe that before many months have passed coal operators generally will turn to some form of co-operative marketing as the most promising form of relief from the serious situation now developing as a result of competitive conditions within the industry. The situation rapidly is becoming as bad as that which existed in 1914, when the Raney resolution was introduced in the House of Representatives at the request of Illinois operators, with the idea of allowing them to co-operate in certain ways so as to save many of them from bankruptcy. A condition of distress even worse than that experienced in 1914 apparently is being approached.

Need of a Moses Is Near

The trend toward consolidations already is under way. While this tendency is regarded as having wholesome features—in fact the late F. S. Peabody publicly urged it as the only way to stabilize the industry—most operators do not want to stand by idly and watch their properties go on the bargain counter.

In the 80's the German coal industry was in much the same condition as that into which the American industry is rushing. It should be remembered that conditions surrounding the production of coal in Germany more nearly correspond to the American industry than do British operations. While Germany produces less coal than does the one state of Pennsylvania, it is thought that a lesson can be learned from experience in that country. When Germany was faced with overproduction and the difficulties it brings in its train, coal syndicates were formed. The largest was the Rhenish-Westphalian syndicate in the Ruhr. The wastes incident to overproduction were

halted at once and the entire industry placed on a stable and efficient basis.

The feeling is that while the government is thoroughly justified in putting forward suggestions when the general public is suffering, it might be misunderstood were the suggestion to come from it in this instance. Since it is the industry which is suffering, the thought is that the initiative should be taken by those engaged in the coal business.

Public Sentiment Undergoes Change

Many unnecessary losses could have been prevented at various times in the past had the American coal industry been at liberty to resort to co-operative marketing. Never before, however, has the situation been so propitious to obtain the necessary legislation. The public has entertained the feeling for many years that coal prices have been inexcusably high and that the recurring shortages had been increased by collusion and artificial bolstering. Public sentiment in that particular, however, is very different today. It is recognized by everyone that in making its three-year wage contract the industry has given bond to produce steadily. It is entirely obvious that present prices are barely sufficient to permit the industry to live. Under these conditions it is believed that Congress will be ready to listen to co-operative marketing proposals. Legislators are unusually well informed on the principles involved, due to their active consideration of the application of this principle to the agricultural industry.

Just at this time Congress is looking with favor on the Yoakum plan, which proposes the combination on a national scale of all former co-operative organizations. This would allow unified selling and unified purchases of all agricultural supplies. No such thought is entertained in applying co-operative marketing to coal. The idea is that there would be forty or more associations. Each of these associations would compete against the others. Under such an arrangement the price of coal to the public would not be enhanced and there would be great public benefit through the stabilization which would

Big Equipment Order For N. Y. Central?

The New York Central, the Michigan Central, the "Big Four" and the Cincinnati Northern railroads have filed a joint application with the Interstate Commerce Commission to issue \$45,630,000 worth of equipment trust certificates.

The money is to be used for the purchase of 189 locomotives, 15,250 freight cars and other rolling stock.

The equipment order is one of the largest ever placed and will bring the rolling stock of the carriers up to a point to meet the needs of heavy fall business.

be made possible. It is not only that there are too many mines but there are too many companies. The same number of mines could be operated to better advantage if handled in groups.

Some such plan is not without governmental support. The Coal Commission recommended large-scale operation. President Coolidge, in his message to Congress, pointed out that opportunity should be given for large-scale production and he hinted at co-operative marketing. There has been other support in administration quarters and some of the closest students of the coal industry recognize in this a constructive move.

Just at this time the thing most needed is suggestion as to how such associations could be operated and how they could be controlled. How could competition between the districts be insured? Should an association be permitted to allocate business pro rata among its membership? If so, should it be on a basis of mine capacity or on output during some previous period of time? Should such an association be incorporated? If so, should it be under state or federal authority? Should the association arrange to close high-cost mines and produce only from low-cost properties? Should such associations be allowed to handle labor relations as well as marketing problems? Should associations be allowed to buy coal from non-members and resell it? These and a myriad of other questions must be answered before any concrete legislative proposals can be made.

No early legislation on the subject is anticipated, but a year hence, when the demand for relief will be acute, it would be well, it is pointed out, to have the groundwork laid and the legislation in such form that its prompt consideration would be possible.

Miners of Southwest Win; Renew Scale for 3 Years

Coal miners of the Southwest scored a victory May 3, when the Scale Committees of the Southwestern Interstate Coal Operators' Association and the United Mine Workers of Kansas, Oklahoma, Arkansas and Missouri signed a contract renewing for three years the wage scale of 1923. In the joint conference which began in Kansas City, March 28, the operators had demanded a reduction from \$7.50 to \$6.00 a day in the pay of day and monthly men. The miners, however, demanded renewal for three years of the old contract. The new contract differs from the old only in a few details. Chief of these is a rule requiring final submission for arbitration of disputes to a commission composed of W. L. A. Johnson, commissioner of the operators' association, and John P. White, former international president of the mine workers.

Central Pennsylvania Miners Accept Wage Cuts

Miners employed by the Consolidation Coal Co., at Myersdale, Somerset County, Pa., after a month of idleness, have accepted the terms of the company and resumed work at reduced wages on May 1. The new arrangement sets the price of loading at \$1 per ton and assures the miners reasonably regular employment.

One hundred and twenty-five miners have returned to their places in the mines of the Vinton Collieries Co., in Vintondale, Cambria County, Pa. Twenty-five more eviction suits have been started by the company to get possession of houses occupied by miners who refuse to work. This makes a total of 58 ejectments started and 33 families have moved out. The wage cut at Vintondale amounts to 33½ per cent for day men and 20 per cent for miners. No. 6 mine is in operation and 152 coke ovens have been fired. The strike which tied up the Vinton collieries became effective on March 17.

Union Official Resigns; Blames Outlaw Strikes

Because recent conventions of Subdistricts Nos. 3 and 4 of District No. 17 as well as some of the union officials of the district have put their stamp of approval on unauthorized strikes, Andrew W. McComas, president of subdistrict No. 4, has tendered his resignation to C. F. Keeney, president of District No. 17, and it has been accepted. James L. Studdard, vice-president of the district, has been designated to succeed McComas, and James McCleary, a district organizer, has been appointed as vice-president.

The resignation of McComas is an outgrowth of a strike at the Grant Town mine of the New England Fuel & Transportation Co. several months ago. When the men quit work, McComas took the position that the strike was in violation of the contract with the operators. He therefore directed that the strikers return to work. When they failed to do so, the charter of the local union was revoked and that action was upheld by the International headquarters of the union. When the matter was finally settled, however, the charter was restored and the outlawed members were reinstated.

Members of the Grant Town local wanted the scalp of the subdistrict president, however, when the subdistrict convention was held, and for a time it seemed likely that formal charges would be brought against McComas, but it was finally decided that charges could only be brought in a district convention.

The New England Fuel & Transportation Co. did not accept the Baltimore agreement.

Coal Wholesalers to Study Oil Competition

Competition of oil with coal will be one of the subjects for discussion at the annual convention of the American Wholesale Coal Association, at White Sulphur Springs, W. Va., June 3 and 4. Among the phases of the subject that will be discussed are the following: To what extent has oil displaced coal? What further inroads may be expected? Is the competition substantial and permanent or is it merely temporary and passing? Is oil an economical fuel? Is the supply regular and dependable?

It is felt that this discussion will bring out the relative values and costs of the fuels in question, together with the outlook for regular and continuous supply of each for the future. Many other questions of timely interest to those engaged in the distribution of coal will be considered.

Attorney General to Study Issuance of Trade Data

Some clarification of the subject of trade associations and statistics is in prospect as a result of the change in attorneys general. Mr. Daugherty gave this controversy very little personal attention, but he was willing to stand behind certain of his assistants who have assumed what is regarded both in and out of government circles as an unreasonable attitude. It is believed that Mr. Stone, the new Attorney General, will insist on determining this policy for himself. It is known positively that he has not given study to the subject, but he recognizes the importance of having some determination of the matter.

The same staff is on duty at the Department of Justice under the new Attorney General as when Mr. Daugherty was in office. There is reason to believe, however, that Mr. Stone will not leave the determination of such important policies to subordinates. It is understood that he is acquainting himself thoroughly with the situation and is willing to take into careful consideration any suggestions which may be forthcoming from those who believe trade statistics are in the public interest.

Strike at Glen Alden Mines Collapses

Indications point to a resumption of work at all Glen Alden Coal Co. collieries in Luzerne and Lackawanna counties, Pennsylvania, this week. The outlaw strike which broke out April 30, completely tying up the collieries and resulting in the idleness of nearly 20,000 men, collapsed over the week-end, when seven of fifteen collieries affected resumed work.

Disregarding pleas of district officers of the union that they remain at work, the men quit because of the dismissal from the company's employ of an official of a union at Edwardsville, Pa. Two collieries, the Diamond and Storrs, did not heed the strike order and continued operating.

Rinaldo Cappellini, district president, urged the men to remain at work and permit their grievance to come through the proper channels. President Cappellini announced that unless the strike was called off he would dismiss from the miners' union members of the general grievance committee who ordered the strike.

Ninety-Three Bodies Recovered from Benwood Mine Five Days After Disaster

Ninety-three bodies had been recovered last Saturday from the Benwood mine, five days after the explosion which entombed 111 miners of the Wheeling Steel Corporation, near Wheeling, and caused the death of all in the mine at the time. Great difficulty has been encountered in penetrating to the entries where most of the miners met their death. Eight bodies were located in the main entry off entry No. 5 east, where wreckage piled in a heap impeded the work of the rescuers. Later, Chief R. M. Lambie, of the Department of Mines, sent rescue crews to the main entry, where it was expected that ten more bodies would be found.

Chief Lambie said last Saturday morning that he had made no effort to learn the cause of the explosion inasmuch as the department and rescue crews had devoted their energies to the work of recovering the dead. Late in the week two more deputy inspectors were sent for from the southern part of the state. They were C. E. Foster, of Logan County, and Thomas Stockdale, of Bramwell. About this time exploration work was taken over by the Bar-

rackville rescue team of the Bethlehem Mines Corporation. Late last Saturday afternoon they were relieved by the crack New River team, which won the championship for mine-rescue and first-aid work two years ago.

Stone falls and gas have hampered the work of rescue crews since the explosion. Many of the victims of the explosion were found in entry No. 8 north. That entry was cleared of most of the bodies by Saturday, but there was one small section where it was expected that the rescuers would find seven or eight additional bodies.

H. Foster Bain, chief of the U. S. Bureau of Mines, and T. T. Reed, of the Bureau's technical staff, reached Benwood late last week to inspect the scene of the disaster and make a thorough investigation to determine the cause of the accident.

About the middle of last week—two days after the explosion—rescue workers were drenched and their work greatly impeded when water broke through the roof and poured down the passageways.

Many parts of the mine are badly wrecked as a result of the explosion.

Program of N. C. A. Meeting Practically Complete

Four speakers of national prominence have definitely accepted invitations to make addresses at the seventh annual meeting of the National Coal Association to be held at the Sinton Hotel, in Cincinnati, Ohio, May 14-16, and plans are under way for the fifth speaker. With this exception the convention program is practically complete. The list of speakers as it now stands and the subjects of their talks are as follows:

Samuel B. Crowell, of Philadelphia, president of the National Retail Coal Merchants' Association, "Our Customers"; John Lee Mahin, president of the Federal Advertising Agency, of Chicago and New York, "Merchandising"; Melville E. Stone, of New York, counselor of the Associated Press, "The Associated Press"; George H. Cushing, editor of *Cushing's Survey*, "Trade Association Activities."

The forenoon of each day of the annual meeting will be given over to consideration of association affairs. This will enable delegates who desire to do so to attend the Exhibition of Mining Machinery and Equipment and discussions of practical mining problems to be held in Music Hall each afternoon throughout the week under the auspices of the American Mining Congress.

Plans are under way for a big public meeting to be held in Music Hall on Wednesday evening. The program for this meeting includes speeches to be made by nationally known figures, which will be broadcast by radio.

The committee of secretaries of the National Coal Association to which was delegated the duty of studying the statistical work of the national and local associations, with a view to expanding such activities and harmonizing them,

will submit the following conclusion at the national convention:

"As to the legality of statistical work of associations, doubt about which has been raised by recent decisions of federal courts, your sub-committee finds in these decisions and in the opinions of counsel that the only illegal phase of such activities is in the use made of such statistics. In every instance in which conviction has been secured, the evidence has shown conclusively that improper use has been made of the statistics. We believe, therefore, that all of the statistics herein considered, with the exception, perhaps, at this time, of past sales reports, are entirely legal.

"It is recommended that where the local associations are not now collecting production figures they arrange to do so, beginning at once, either on a daily or a weekly basis, this information to be collected on the forms prescribed by the Geological Survey."

Mine Inspectors Discuss Rock-Dusting Progress

Rock dusting received careful consideration at meetings of Pennsylvania bituminous mine inspectors called by J. J. Walsh, State Secretary of Mines, at the Seventh Avenue Hotel, Pittsburgh, April 29 and 30, to discuss accidents and the means to prevent them.

The reports of the inspectors relative to the reception of the rock-dusting movement in their respective districts is indeed encouraging. Many of the coal companies have expressed their desire and intention to adopt this measure of safety just as quickly as ways and means of so doing are provided. They are looking for means of crushing limestone or shale, preferably the former, and for ways to distribute the dust.

The Pennsylvania mine inspectors to a man are in favor of rock dusting. They, like others, see no other way to prevent coal-dust explosions, having lost all faith in methods of wetting down coal dust by sprinkling or humidification.

So firm a grip has the advantage of rock dusting on the minds of bituminous-mine operators and engineers in the State of Pennsylvania that Secretary Walsh believes it will be adopted voluntarily, and prior to the enactment of state laws. Millions of dollars no doubt will be spent during the next year in the installation and use of such equipment.

To Submit Records Promptly

Because accident and fatality statistics as compiled in annual state reports are several years old when they are made available for distribution, a plan was adopted at the meetings by which each inspector will present the companies and the workmen in his district with the various records as they are compiled and will discuss these data with them. Companies will be consulted individually or in groups. Separate conferences will be held with mine officials and workers. By an analysis of the records of each company and a comparison with those of others, the inspectors hope to impress upon the officials and miners the need for and means of accident prevention.

Bituminous Mine Inspectors of Pennsylvania Meet in Pittsburgh

When Secretary Walsh, second from the left in the front row, called a meeting of his inspectors, primarily to discuss rock dusting, he was met with a 100-per cent attendance.

Navy Department Seeks Bids For Year's Coal Supply

The Bureau of Supplies and Accounts of the Navy Department, Washington, D. C., announces the opening of bids May 21 at noon for supplying coal during the fiscal year beginning July 1, 1924, to navy yards and naval stations. Tenders are asked on bituminous or semi-bituminous coal, run of mine, for the following stations, the amounts specified being in gross tons:

Boston Navy Yard, 30,000 tons; Chelsea (Mass.) Naval Hospital, 5,500; South Brooklyn Navy Supply Depot, 8,500; New York Navy Yard and Naval Hospital, 54,500; Iona Island (N. Y.) Ammunition Depot, 2,000; Lake Denmark (N. J.) Ammunition Depot, 1,800; Lakehurst (N. J.) Naval Air Station, 12,500; Philadelphia Navy Yard, 25,000; Annapolis Naval Academy, 35,100; Annapolis Engineering Experiment Station, 1,200; Washington (D. C.) Navy Yard, 50,000; Naval Research Laboratory, Bellevue, D. C., 1,050; Indian Head (Md.) Powder Factory, 28,000; Naval Proving Ground, Dahlgren, Va., 5,000; Hampton Roads (Va.) Naval Operating Base, 21,000; Norfolk (Va.) Navy Yard, 25,000; Portsmouth (Va.) Naval Hospital, 5,500; Navy Mine Depot, Yorktown, Va., 1,500; Charleston (S. C.) Navy Yard, 4,000; Naval Air Station, Pensacola, Fla., 6,000; Great Lakes (Ill.) Naval Training Station, 5,500 tons of run of mine and 34,500 tons 1½ in. screenings.

Bids on semi-bituminous coal for ships are asked for the following amounts, in gross tons: New York Harbor, 20,000 tons; Philadelphia, 10,000; Hampton Roads, Va., 300,000. For anthracite, bids are sought on amounts from 50 to 2,000 tons for a number of posts in the East.

The Coal Center of New York

The Whitehall Building, 17 Battery Place, houses more coal offices than any other building in the city.

Output of German Coal Mines Attains Pre-War Level

Nearly all the branches of the German coal industry have attained the pre-war level in output. Coke and bituminous coal are slightly under the pre-war figure, but production of lignite, upon which energy has been thrown since the Ruhr occupation, has increased more than 60 per cent.

The total production in March of bituminous coal, coke and lignite throughout Germany, exclusive of the Sarre Basin, was 26,000,000 tons against 22,600,000 for March, 1913.

International First-Aid Meet Postponed

The international first-aid and mine-rescue meet, scheduled to be held at Huntington, W. Va., in September under the auspices of the U. S. Bureau of Mines, in conjunction with the Huntington Chamber of Commerce and various miners' and operators' associations and organizations, has been postponed with the approval of the Secretary of the Interior following a conference between representatives of the Bureau of Mines and the West Virginia committee in charge of arrangements.

Since the announcement of the 1924 meet was first made the Bureau of Mines has received letters from various parts of the country indicating that in view of the depression in the coal industry it would be difficult to insure enough teams attending to make the meet representative of the whole country.

Idle Miners Absorbed by Other Industries

The telegraphic survey of employment conditions throughout the nation conducted by the Labor Department immediately following the close of each month refers only incidentally to unemployment in coal-mining regions. Reference is made to decreased employment in coal mines in Pennsylvania, Ohio, Illinois and Indiana, but the general summaries of those states show no abnormal unemployment, which is interpreted at the Employment Service to indicate that coal miners are being readily absorbed by other industries. Some unemployment of coal-mine labor is reported in Alabama, but in West Virginia some of the labor released in February found work during March.

Problems In Underground Management

Advice to Those Using Mechanical Loaders

Judicious Shooting Will Speed Loading—Switches Between Rooms
Will Save Time—Take Trolley Into Rooms
and Use Short Cable

BY CHARLES H. THOMPSON

Mining Engineer
Hollis, Va.

SUCCESS in operating loading machines will be determined by the degree to which all co-ordinating factors are made to synchronize and aid in the loading of the coal. It is necessary to consider not only loading but the mining and shooting of the seam, and the transportation of the product to the tippie.

In installing mechanical loaders, use only such systems of mining as already have proved successful in the seam to be worked. Room-and-pillar methods are generally preferable. Avoid the miners' habit of shooting too few shots. Use mechanical drilling, and then there will be no need to avoid the labor of putting in the requisite number of holes. The miner is sparing in the use of holes, not because he thinks large shots save labor in shoveling or produce better coal, but solely because it saves the labor of drilling holes. With more holes the coal will be shot down with less damage to both coal and roof and with greater safety to the men employed. Shoveling will be easy if the coal is properly but not excessively broken.

BETTER MAIN-LINE TRANSPORTATION

Transportation is made rapid and free of accident by maintaining good track, properly located wiring, motive power in good condition, well-ordered rolling stock and efficient bonding. The labor to afford these for a given output is greatly reduced when manual loading gives place to mechanical, and consequently with machine loaders all these items can be kept in first-class condition without excessive cost.

Lay out the plan of working so as to determine beforehand every dimension and every angle. Follow this plan with an allowable error of one foot in distance and two degrees in angle. Templates are easily made, and paint is cheap. They will guide the cutters until the surveyor puts up his points. Plan track and wire so that what will fit one place will fit another. Simplify your workings, and you will reduce costs.

Put crossovers in your rooms from one rib track to another and from one center track to the track in the next room, thus the rooms can be made twice

as long as they could be made economically without these facilities. If crossovers are put from room to room at each crosscut, much time will be saved in transferring cutters, drills and loaders from one working place to the next.

Use a small No. 2 trolley wire on one room track and work from this with a 75-ft. hand cable. Cut your wire to suit the length of room agreed on and play it out as the room is advanced. Old Ford tires make a handy insulating cover, and extended clapboards with light barn hangers make a satisfactory protection. This saves the time, trouble and expense involved in the use of clumsy duplex cables. Let your gatherer bring enough cars to clean up an entire narrow face or half a wide one. While he goes to get another turn of empties the loading machine can be moved to its next place and be ready to load when he returns. A half minute lost on a 3-ton car

means one minute on 6 tons or, where a loading machine will load a ton a minute, 16⅔ per cent of lost time.

Advance your track heads by use of the inverted-rail and chair method or by the use of inside-point rails and cuffs. Don't allow jumpers to be used. Cut your straight rails to standard length.

Don't mix mechanical loading with manual in the same entry. It can't be done satisfactorily. Put a group foreman in charge of all the cutting, drilling, shooting, track, timber, wire and haulage, which one loading machine requires. The proper number of machines for the entire job soon can be discovered. Pay the men well for a fair task and offer more for a better one. The coal will then move regularly, and a healthy competition will keep the crews at their best.

PREPARE YOUR COAL ON SURFACE

If your seam carries partings, spend part of the saving in preparing the coal on the outside. The final saving in your cost for a marketable product is what you are seeking.

You will find the following advantages in mechanical loading: (1) The coal will cost less and be worth more as it will be an improved product; (2) the men will make better wages by the

Wide World Photos

Undercutter at Work in Wilhelmina Coal Mine, Holland

Note the way in which a large prop is used as a cap piece and is carried over almost to the face of the coal. Also observe the screw jacks with their rapid releasing levers. A snug place to work a coal cutter in, low as to height and narrow as to width of working space. However, the coal appears clean but with irregular cleat.

Hoisting Pit Ponies

Some of the pit ponies in England are what their names signifies, but some, as the illustration shows, are of more stalwart build. Ponies rarely come to the surface except in case of a strike.

elimination of lost time; (3) the risk of serious accident will be reduced as fewer men will be employed; (4) less territory will be opened for a given output with attendant savings in operation; (5) a premium will be laid on intelligence and skill, and hence the living conditions in mining communities will be improved; (6) excavation will be speeded with consequent advantages in handling roof, in recovering ribs, in salvaging of timber and track etc.; (7) the overall investment for a given output will be lowered.

What Rock Dust Costs and How Much Is Needed

By JOHN T. RYAN*

Concurrently with undertaking any program for rock dusting coal mines the relative flammability of the coal should be determined. The Bureau of Mines is always glad to co-operate in this matter and is in a position to render this service.

The raw material for rock dusting should contain little or no free silica and be low in combustible matter. Pure limestone is an admirable material and shale is good. Usually one of the shale formations associated with the coal measures is suitable for rock dusting and it should be given preference, for it is economical to have the source of supply at the mine.

A plant to pulverize the dust to the proper fineness should consist of a simple preliminary crusher to reduce the material to $\frac{3}{4}$ in. and a pulverizer which will grind the material to powder so that it will all pass through a 50-mesh, and so that at least 70 per cent will pass through a 200-mesh screen. This equipment preferably should be installed at the mine or underground if possible, and an equipment having a capacity of 1,000 lb. per hour is ample.

The next essential equipment is a distributor that will spread the dust properly underground. This equipment should be so designed that it will first air-blast the coal dust from the ribs, roofs, etc., and then dust the same faces with the shale dust. It should have a capacity of 1 lb. per second at a speed of not less than one mile per hour. It should be able, also, to de-

liver dust to the back of trackless entries at desirable points, relying on the ventilating current to act as the distributor.

Rock-dusting should be done first on all haulageways up to and including room-necks, and up to and including the face of all development workings.

A simple sampling kit should be installed. The purpose of this is to take samples and analyze them for determining the quantity of incombustible material. This should be so simple that the average man about the mine could operate it and run a test in a few minutes. Such a kit has been developed by the Bureau of Mines and is now ready for the market. Samples should be taken twice a month at predetermined points, except in heavy haulage entries where it may be necessary to distribute the dust once a week. A month should never pass without an application of rock dust. Experience will quickly show where and how often samples should be taken.

CLEAN AND ROCK-DUST ENTRIES

All entries should be cleaned up as thoroughly and frequently as necessary and should be rock-dusted so there will be no more than 50 per cent combustible matter present at all times. The explosibility tests of some coals may indicate that there should be 70 per cent of incombustible material.

Mine operators are compelled to study the rock-dusting problem from a viewpoint of cost and the scientific facts must be reduced to an economic, commercial basis. We cannot rock dust our mines as they are rock dusted in Europe, because our mining and labor

Table I—Cost of Crushing and Pulverizing Plant

Pulverizer	\$1,500	
Crusher	500	
Two elevators	350	
Two bins	150	
Motor and accessories (20 hp.)	350	
Sampling and analytical kit	75	
Distributor	500	
Auxiliary car	100	
Building	1,800	
	\$5,325	
Total cost of installation		\$5,325.00
Interest at 6 per cent for 20 years		6,390.00
Amortization, 20 years		5,325.00
		\$17,040.00
Cost per ton on an 8,000,000-ton (or 20-year basis)		\$0.00213

conditions are vastly different. It is claimed in Great Britain that rock-dusting costs 0.1c. per ton of coal mined. Costs in America on a twenty-year basis should be less than 1c. per ton. A reliable commercial pulverizing company quoted an operator in the Pittsburgh district \$4 per ton for limestone dust in carload lots, f.o.b. factory. To this would have to be added about \$2.50 for transportation and handling.

Tables I and II give respectively an estimate of the initial cost of rock dusting equipment for a 400,000-ton mine on a twenty-year basis, and data regarding the cost of making and distributing rock dust with the basis for the estimate.

Table II—Cost of Making and Distributing Rock Dust

Crushing and pulverizing	\$1.00	
Distributing		1.55
		\$2.55
Approximate length of entries to be dusted in an average 400,000-ton per year mine, miles ..	50	
Average quantity of dust required for each mile, tons	1.8	
Quantity required for one dusting, tons	90	
Quantity required per year, tons ..	360	
Cost at \$2.55 per ton		\$918.00
Cost per ton of coal on yearly production of 400,000 tons		\$0.0023
Installation and depreciation ..		0.00213
		\$0.00443

Rock dusting has many added advantages; for instance about 90 per cent of the light underground is absorbed by the coal. Rock dust, and particularly that prepared from limestone, greatly improves the illumination, and consequently increases the efficiency of the workman and decreases accidents. Rock dust is an efficient fire-fighting material, and is no doubt much safer to use than either water or chemicals. It is likewise believed that it has special merits as a stemming material for shotholes as compared with clay and many other inert substances.

Danger in Driving Rooms Up the Coal Pitch

In the current issue of the Union Pacific Coal Co.'s *Employees' Magazine*, Thomas Fraser, superintendent of the Reliance mine, declares that accidents are more frequent when rooms are driven up the pitch than when directed along the strike. Snubbing and spragging cars are alike dangerous. When they are snubbed the rope sometimes breaks and allows the car to run down the inclination at a high rate of speed. Occasionally the snubbing post is pulled out. Legs and arms are caught in the snubbing rope. More accidents, however, probably are caused by spragging. When the roof is bad or the coal is dirty, the track becomes littered, and the miners are liable to have their hands injured when trying to sprag cars. Another danger is from the coal at the face which overhangs the working face when the room is driven up the pitch. When the miner pulls down the coal from a down-pitch position the coal is likely to fall on him and injure him. In work parallel with the strike of the seam the risk is far less.

*Vice-president and general manager, Mine Safety Appliances Co., Pittsburgh, Pa.

Practical Pointers For Electrical And Mechanical Men

Protective Apparatus for Substation Equipment

The articles which recently have appeared in *Coal Age* on the protection of the motor-generator sets and rotary converters used at mining properties have attracted much attention among the electricians at our mines. The main reason for the interest these men have shown is due probably to troubles which have been experienced by some of the mining companies located near us.

Our company has now almost established standards for the protective equipment used in our power-converting substations. The main incoming alternating-current circuit is protected by three overload induction-type relays. These relays are set so that they will trip only when the load on the alternating-current circuit has reached a

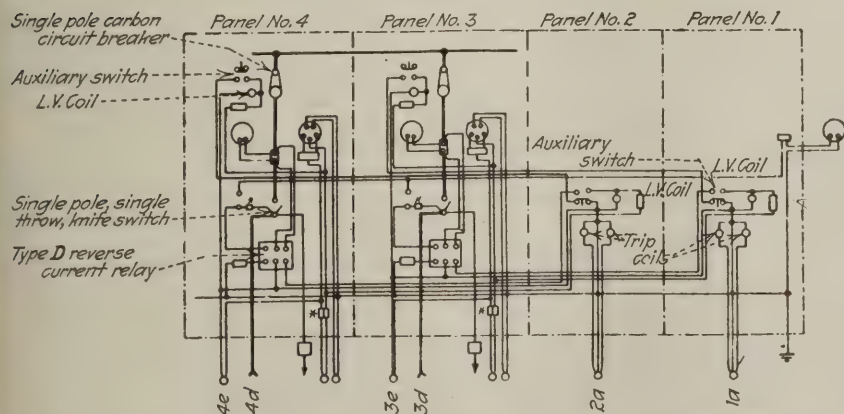

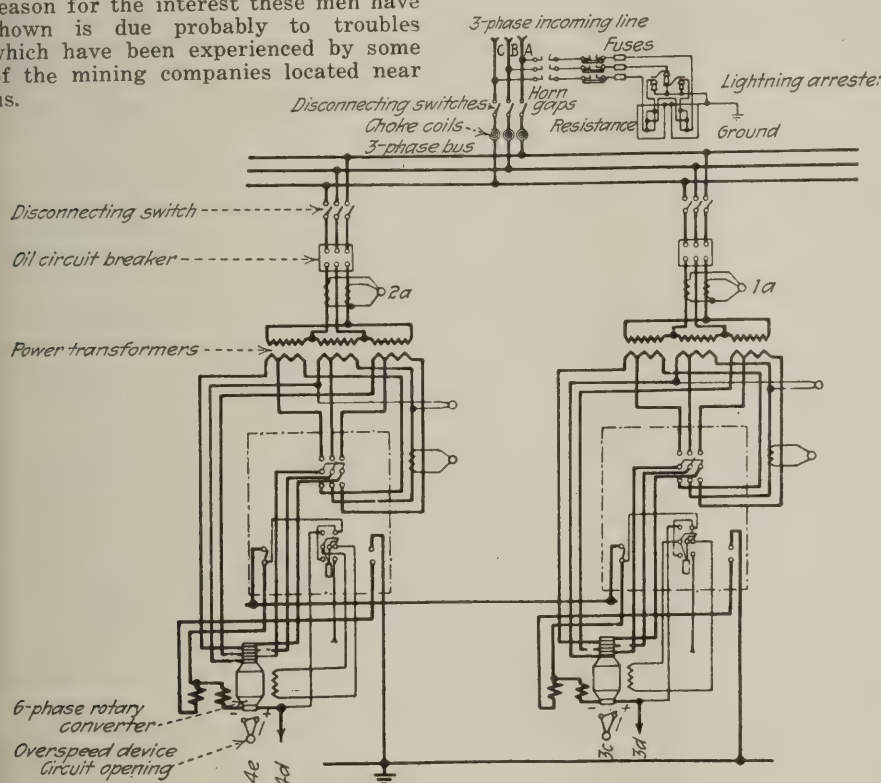

value about 200 per cent over the full-load capacity of the converting equipment. The direct-current circuit is protected by a main-generator breaker and several independent feeder breakers. With this arrangement the direct-current end of the power-converting system is doubly protected against overload because an overload on any of the feeders is taken care of by a feeder breaker before the main-generator breaker is affected.

Another important feature is the overspeed device located on the shaft of the motor-generator set or the rotary converter. Whenever any circumstance arises which causes the converting equipment to run at a speed higher than normal this little device operates and disconnects the equipment from both the alternating- and direct-current lines.

A reverse-current relay generally is connected in the direct-current line. Its function is to open the main direct-current circuit breaker should the generator be motored from another source of direct-current energy either in the same station or a remote substation.

It is our general practice to order all our substation equipment furnished with all these protective features, because we feel that the extra cost of having these parts supplied with the original order is much less than the cost of adding them at some later date when we desire to interconnect our machines.

G. D. CAMERON.

Two Rotaries Completely Protected With Auxiliary Tripping Relays

When machines operate in parallel the liability of damage to one or the other is increased. However, when properly protected there is little danger of accident or breakdown. Standardization of switchboard panels and equipment greatly simplifies the work of inspection and protection.

Match Trolley-Wheel Grooves To Overhead Fittings

How the size, kind and shape of trolley wheels affect the proper maintenance of the trolley wire and its attachments is a subject more or less neglected, but nevertheless of great importance. The specifications for trolley wheels are broad enough to allow the selection of wheels varying in width from 1½ in. to 1¾ in., the grooves of which may be of any one of various shapes. The company by which the wheel is supplied frequently gives no consideration whatever to the path over which the wheel must operate.

The trolley wire itself may vary from 1-0 round with a diameter of 0.324 in. when new to 4-0 grooved with a diameter of 0.482 in. as it comes from the factory. After being in service, the diameter is often reduced to 0.25 in. or even less, which undoubtedly causes a deeper groove to be worn in the wheel.

If the wire only were to be considered the problem would be much simpler, but wire must have attachments,

Figs. 1 and 2—U-Shaped Wheel Fits Wire Best

The first figure showing the U-shaped wheel makes a better contact with the wire than the V-shaped wheel which makes contact only on the sides of the groove.

such as frogs, section insulators, splicers and cross-overs, which sometimes more than double the diameter of the path for the wheel.

POOR FIT OF WHEEL IS EXPENSIVE

There is no way to compute how greatly the cost of repairs, replacements and maintenance of an overhead system is increased by the general indifference as to the fit of the trolley wheel and the trolley wire. In my opinion, formed from my own experience and talks with many active operating men, much of this maintenance expense could be eliminated were more consideration given to this important point. I have been given so many greatly varying figures on wheel mileage that it is impossible to strike an average. These figures vary from 100 to 20,000 miles per wheel.

There is a vast difference between the service demands on trolley wheels, but the life of the wheel should depend mainly on the speed and tonnage of the equipment and not on factors which we are better able to control. Most mines use grooved trolley wire which almost entirely removes the trolley ear from direct contact with the wheel.

Much could be said also of poor maintenance of current collector equipment, such as stiff, sluggish bases, bent trolley poles, lack of proper and uniform trolley-base tension. The trolley wire, besides acting as a current supply to the locomotive, must also act as a track or guide for the wheel, and a trolley wire even if in proper alignment will be subjected to unusual wear and burning if the collector is not properly maintained.

ELIMINATE OBSTRUCTIONS ON WIRE

Dewirements of trolley poles, like derailments of locomotives, are caused by obstructions. These are often absolutely necessary overhead appliances, but with properly maintained collectors they would not be obstructions and would not cause dewirements. We have all seen many locomotives pass successfully through complicated overhead work only to note another locomotive dewatered when passing the same point, suspending or delaying all traffic. The cause of this could usually be found on that individual locomotive, but it is frequently necessary to call out the electrician to repair the damage and replace broken wire or appliances.

A considerable saving may be obtained by a closer study of trolley wire; its necessary attachments and the collector equipment, consisting of bases, poles, harps and wheels. Trolley wire

and the entire overhead current-carrying equipment is burned out rather than worn out by service, and anything which can be done to obtain at all times a better electrical contact between wheel and overhead wire and fittings will tend to increase the life of the equipment and decrease costs.

G. F. ROACH.

The Ohio Brass Co.

Metal Electrode Welding

There are several different methods of welding by electricity, but the one most commonly used is by means of a metal electrode. The operator uses a rod of low carbon steel with which he draws an arc, fusing the metal of the electrode onto the work. The process is comparatively slow but uses a relatively small amount of energy. The metal is deposited more uniformly, the weld is stronger and the finished work is more regular in appearance than when done by the carbon electrode method. As the deposited metal is carried directly to the weld by the arc, this method of welding can be used on vertical surfaces and overhead work. For these reasons the metal electrode weld is more generally used in connection with all-round repair work.

An Economical Way to Cut Slots in a Spray Pipe

Nozzles for spraying water over the long screens used in coal washers do not always satisfy the requirements. If a large number of nozzles are provided it is necessary to use many pipe couplings at the expense of much fitting, whereas if only a few are used they must be operated under such high water pressures that most of the water is lost due to the high velocity with which it strikes the coal or screen.

Pipe, however, can be slotted so as to give satisfactory service, for the slots may be located exactly where needed. Slotted pipe have the further advantage that several orifices are located in a single pipe and thus few couplings or fittings are required, which to connect consume too much of the repairman's time.

OXYACETYLENE PROCESS IS BEST

When our company first resorted to the use of slotted pipe, short holes were cut into the side of the pipe by a milling machine. This method was slow and consequently expensive. When the demand for slotted pipe increased, it was necessary to find some quick and economical method for doing the cutting in the shop, and, when necessary, in the field.

After trying several methods, the oxyacetylene process was tried and it proved to be the most economical, quickest and most adaptable. The position of the slots is chalked on the pipe in accordance with specification, which state the number of slots per foot. By using a two-wheel guide attached to a hand-cutting blow pipe, the cutting is made simple and easy. The slot is narrower at the outside surface of the pipe, the cutting jet being purposely directed

so as to make a bevel cut into the pipe wall. In many cases the slot must be so narrow that a dime will just pass through under finger pressure.

Pipes 6, 8 and 10 in. in diameter may be slotted by this method. An operator can slot an average of three standard lengths of 8-in. pipe in one day. The cost of cutting is from 60 to 80 per cent less than by the old method of milling.

Perforated pipe have many uses. They may serve as strainers, sprays and sprinklers, also as injectors and drain pipes. Even where large quantities are not needed it is well to take advantage of the economy and utility of this method of perforating them.

P. T. CONNELLY.

Stopping Flash-Over on Rotary Converters

A mine rotary of reliable design had been flashing from the alternating-current rings to ground and from phase to phase, with the usual results of melted brass and iron, damaged brushes and ruined pigtails, when an investigation by our department was requested. Every electrical test that could have a bearing on the case was made, with the hope of finding transformer trouble, sudden overloads, etc., but nothing unusual was discovered. No trouble was experienced from other rotaries which took power from the same alternating-current supply and delivered direct-current into the same distributing system. The problem was perplexing.

Transformer cores were taken out of their tanks for careful inspection; low-voltage compression chamber arresters were connected from phase to phase near the alternating-current rings to drain or equalize any high-frequency current that might build up. Field circuits and air gaps were tested, and recording instruments were placed in the field circuit and main circuit to ascertain the behavior of the machine when it flashed over.

SAME MACHINE GAVE GOOD RESULTS

In conversation with some of the operatives at the plant it was learned that all these tests had been made by the local electrician. A machine, the exact duplicate of the one giving so much trouble was being operated in a nearby station and gave excellent results requiring little or no attention.

Visual observation of the machine disclosed the following facts: one of the alternating-current metal and carbon brushes would start a small spark, and in a few minutes long streaming flashes developed until finally the rings flashed over.

Barriers made of asbestos and tape were built up between the slip rings and placed so as to avoid air blasts and dust traps. A slight vibration of the top of the alternating-current yokes was stopped by tying them securely to the bearing pedestal cap. Since that time the brushes have been kept properly lubricated and no further trouble has been experienced.

ENGINEER.

Production And the Market

Sogginess Lingers in Bituminous-Coal Markets; Prices Sag; Production Lower

There has been no discernible upturn from the soggy condition prevailing of late throughout the bituminous coal trade. Reports of shutdowns are less frequent, probably for the reason that they could not go much further, but the operations that are working are on low running time. Most of the business being placed is from railroads, with the usual scattered emergency buying accounting for a large proportion of the remainder. Placement of contracts is still noticeably backward and the movement of tonnage destined for shipment up the lakes is far from impressive. Nevertheless an improvement of undertone is perceptible, the diminished movement of tonnage having served to stabilize the markets by eliminating distress coal as a disturbing factor.

Prelude to a Busy Season?

A number of close observers profess to see the present as a transition period—a between-season pause preceding the usual preparations for an autumn revival of business. Speaking of preparations, the New York Central R.R. and allied lines plan enormous additions to rolling stock, the purchase including 189 locomotives and 15,250 freight cars. The new equipment will involve an outlay of \$45,630,000, the roads having applied to the Interstate Commerce Commission for permission to issue equipment certificates for that amount. This, taken in conjunction with the recent \$28,000,000 order placed by the Chesapeake & Ohio and the reported intention of the Pennsylvania to make a large outlay for the same purpose is convincing proof that the railroads of the country are getting themselves in readiness for a revivification of industry.

The wage dispute that caused a shutdown of the union mines of the Southwest was settled May 3 with a victory for the miners, the joint scale committee of

miners and operators having agreed to renew the old scale for three years, the only change in the contract being a provision for submitting matters in dispute to an arbitration commission. The operators sought a 20-per cent reduction in wages.

Coal Age Index of spot prices of bituminous coal resumed its recent downward trend during the last week, the May 5 figure being 169 and the corresponding price \$2.05. This compares with \$2.07 on April 28 and \$2.66 at this time last year.

Dumpings at Hampton Roads for all accounts during the week ended May 1 totaled 326,962 net tons, as compared with dumpings of 264,758 net tons in the preceding week.

Dumpings of cargo coal at Lake Erie ports during the week ended May 3, according to the Ore & Coal Exchange, totaled 500,740 net tons; fuel, 20,708 tons. This compares with 341,231 tons of cargo coal and 23,259 tons of fuel coal dumped during the previous week.

Production of bituminous coal took another flop during the week ended April 26, when, according to the report of the Geological Survey, the output totaled 6,726,000 net tons, a decline of 192,000 tons from the previous week. The decrease is attributed largely to the partial observance of Easter Monday as a holiday. Anthracite output also declined, 1,205,000 net tons having been produced, compared with 1,623,000 tons during the week before.

Demand for anthracite continues strong, much of the last-minute April business carrying over into May. Consumers are placing orders in such volume that retailers' yard stocks are not accumulating appreciably. All of the companies and most of the independents advanced prices on domestic sizes 10c. to 20c. per ton May 1.

No Life Yet In Midwest

General sogginess of the market continues throughout the Midwest. Some screenings business always is available at fair prices but there is no demand for prepared sizes and all the usual troubles of such a situation are experienced. Midwest fields are shut down as low as ever in history, so that production is down almost out of sight. A survey of operating conditions in Illinois shows well over 100 mines of the 393 shipping units of the state shut down for good with fans and pumps stopped. Almost as many are down with indefinite plans for reopening, thus leaving possibly 150 in active condition. These are getting slim running time except the few having contracts for their entire output.

The only events of interest in domestic business that marked the incoming of May were a definite drop in Pocahontas mine run to \$2 by all companies and an increase of about 10c. on all sizes of anthracite by both old-line companies and independents. There is practically no anthracite business. The dealers have been thinking there might be further drops in hard coal at the mines and have declined to stock. The May 1 hoist and the promise of further upward movements each month hereafter are calculated to stir dealers to buy.

Railroad tonnage has fallen off and an air of quietness has crept over the southern Illinois field in the last two weeks that is discouraging to the miners and the only ray of hope lies in the fact that the west Kentucky miners who are on strike may continue out. No change is noted in the situation in Duquoin and Jackson County. Running time is low and there is little business except for railroads. In the Mt. Olive field things are practically at a standstill, excepting on railroad tonnage, with no change in prices. In the Standard field the few mines that are working are selling at production cost or lower.

Business is quiet at St. Louis. Practically nothing is doing in domestic excepting the movement of small cars for emergency purposes. Buying of high-grade Illinois, smokeless, anthracite, coke and Arkansas has not started, but it is expected to get under way this month. Wagonload steam has practically stopped.

Kentucky Business Slow

Operating mines in the western Kentucky field are fairly busy on account of the large number of mines tied up by the miners' strike, but there is little business on prepared sizes, so it is hard to produce enough screenings to meet the demand. Screenings are selling at the mine-run price,

Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines				
Index	1924			1923
	May 5	April 28	April 21	May 7
Index	169	171	169	220
Weighted average price.....	\$2.05	\$2.07	\$2.04	\$2.66

This diagram shows the relative, not the actual prices, on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913-1918," published by the Geological Survey and the War Industries Board.

\$1.60@ \$1.75 to the trade, while some mines are unable to accept screenings orders unless the buyer will take lump and egg too. West Kentucky strippers are reported as busy producing something over 120 cars a day. The strike is not having any material effect on the market, as with the present lack of demand for prepared, screenings would be scarce and high.

The Louisville trade reports a continuation of slow business, due to general lack of demand. A little tonnage is moving from the Hazard field to lake ports and there also is some steel-mill business. Utilities and large industries are not buying much coal, and steam-plant demand is slowing up fast, while retailers are buying only very small lots. There has been some railroad contract business placed, but the volume as a whole has been small.

In spite of relatively small production of prepared sizes in eastern Kentucky, screenings are being offered as low as 90c. in the Hazard field, and up to around \$1.25 for the best grades of Harlan gas screenings. High prices and small production of screenings in western Kentucky are resulting in a better consumption of eastern Kentucky screenings in the Louisville market, as they can compete on price in spite of a 43c. to 53c. freight-rate differential in favor of western Kentucky.

Northwest Prices Flutter

Soft-coal prices rose in Duluth May 1 and fell in Milwaukee, indicating the Duluth-Superior docks are going to quit giving coal away. Arrival of cargoes and a raise in price of bituminous are the only features of a very dull market at the Head-of-the-Lakes. Since the opening of navigation 31 boats have arrived, 10 bringing anthracite.

New soft-coal prices at Duluth are: Kentucky lump, \$7; run of pile, \$6; screenings, \$4.25; Youghiogheny lump, \$6; run of pile, \$4.50; screenings, \$4.25; Hocking lump, \$5.75; run of pile, \$4.50; screenings, \$4; splint lump, \$6; run of pile \$5.25; screenings, \$4.25; Pocahontas lump, \$7; run of pile, \$5; screenings, \$4.75.

Duluth docks are ready to ship anthracite to the Twin Cities as soon as the rate on all-rail coal becomes effective, May 27. The soft-coal situation is still waiting, as it has been for two years, on the I.C.C. decision in the Illinois mine-rate case.

The Milwaukee market continues dull, but dealers are looking forward to a moderate revival of trade as a result of a reduction in soft-coal prices which became effective May 1. The cut in prices ranges from \$1 to \$1.50 per ton. Screened Pocahontas, however, was reduced \$2.25 per ton. Coal cargoes continue to arrive. The movement will be much slower than last season, however, because of the large amount of carry-over. April arrivals embrace four cargoes of anthracite and eight cargoes of soft coal, the former aggregating 40,576 tons and the latter 61,499 tons.

Western Business Spotted

Scale committees of operators and miners of the South-western district, in joint session in Kansas City since March 28, finally agreed May 3 to a renewal for three years of the old contract. Mines through Oklahoma, Kansas, Missouri and Arkansas operated by members of the South-western Interstate Coal Operators' Association still are closed, but a few mines outside the operators' association, for which contracts have been signed, are putting some coal on the market. This augments the steady flow to the Kansas City market of coal from other districts, so there has been no hint of shortages.

The coal market in Colorado experienced another dull week. Very little movement of anything but domestic sizes was noted. Mines worked on an average of a little less than half time and the operators report 36 per cent of the lost time due to no market.

In Utah the retailers are buying a little more coal as a result of weather conditions. Mining, smelting and cement plants are providing the best coal market among the industrial concerns. Railroads are buying from hand to mouth. Working time at the mines is around two and a half days a week. Operators are now able to care for all slack orders, due to a slower market rather than an increase in production. The railroad tracks at the mines are still crowded with "no bill" cars.

Ohio Markets Dull; Prices on Firm Basis

Dullness still characterizes the Ohio trade. Steam buying at Columbus is low, as consumers are still using reserves. Although some of the heavier consumers have reduced their accumulations to normal and are coming into the market, many others are content to rely on stocks. The net result is a reduced demand, which is reflected in lesser output in all fields of the state. Little contracting outside of railroad fuel is reported, although there are inquiries. Consumers are content to buy on the open market, believing that contract prices may be reduced later. There is still quite a spread between contract and spot quotations. Little movement in domestic sizes is reported. Lake trade is showing some signs of revival, as there has been some inquiry for tonnage for Lake shipment. But so far little has been done outside of the companies having their own dock connections.

There is sentiment in the Cincinnati market that values have reached a firmer plane than for some time past. The marked strength of the domestic smokeless sizes is one of the features of the market. River business is proceeding in good volume by the shippers who have an outlet through Huntington. A cargo or two has come through from the Kanawha and the word is that some of the operators there that formerly were in agreement with District 17 of the United Mine Workers are getting ready to run on a large scale on the open-shop basis. Only one change has been made in the local retail prices and this was the dropping of the bituminous lump to \$6 a ton. Quotations on specialized coals are as follows: Lump, \$3@ \$3.50; egg, \$2.50@ \$3.

Cleveland consumers seem bent on consuming stockpiles before entering the market for additional fuel in any significant quantities. Most of the inquiries are confined to slack

and nut and slack, and these grades continue scarce, as lump is not being produced either for the Lake trade or domestic purposes. Generally speaking, there is little contracting, and steam buyers depend largely on the open market. Of course, the railroads are expected to be contracting right along, where they and the operators can get together on prices. The first season charters in the coal trade are reported to have been made during the past few days. The railroads have about 8,000 cars at the lower Lake ports.

Production in the Pittsburgh district is at 15 to 20 per cent of capacity. Consumer-owned mines are running better than the merchant mines. Line consumption is decreasing and the spot market continues extremely quiet.

Trade at Buffalo is still quiet, though there is more hopefulness in the tone of the reports made by shippers. Some look for a recovery by July, basing their ideas mainly on the reduction of output.

New England Trade Healthier

The steam trade in New England continues to develop a rather healthier condition, but there has not yet been any comprehensive buying outside of railroad circles. New England shares the general dullness in industry, and in no part of the territory is there much interest in spot prices. The low levels of a fortnight ago have practically disappeared, and quotations seem to show a steadier tone. The trade realizes there is a long distance to go before prices can be influenced by demand, but there is a disposition to counsel operators against mining coal in advance of definite prospects, and if this can be followed for another month or so there will be a better outlook for June and July.

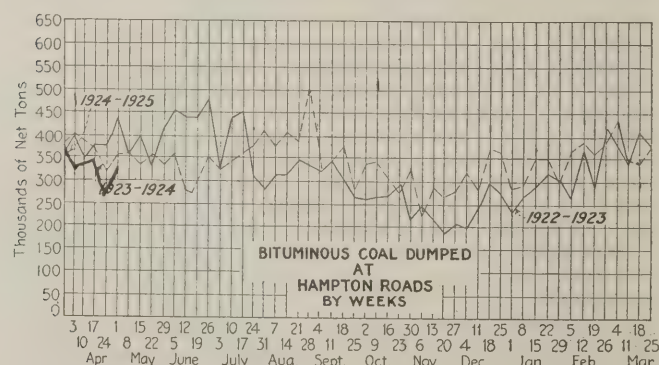

At Hampton Roads the accumulations of Pocahontas and New River average much less than during the early part of April. Prices are measurably improved in consequence, and it may be we have heard the last of "distress" coal for the season. Spot figures are \$4.35@4.50, depending upon grade, and there is a fair chance of the price level being raised another 15c. or so during the week. There is a certain amount of over-sea business offering, although the tonnage is only of moderate size, and this with staple contracts coastwise gives the agencies some encouragement.

Meanwhile, low prices on Navy standard coals have been named for retail delivery through the season, especially in Boston. The School Department of the city was offered New River at \$6.29 per net ton delivered by truck, long hauls as well as short, and this does not argue for sharp advances at wholesale during the summer. It should be said, however, that anthracite trade also is dull, and the retail dealers find themselves in position where their equipment needs to be kept in service on something.

Smokeless coals are being quoted on cars at Boston, Providence and Portland on about the same basis as a week ago. There is only scattering request, and practically all the factors are carrying heavy stocks.

Seaboard Markets Inactive

There is little activity in the New York market. Movement of coal at tidewater has been sufficient to clean up "distress" coal, but occasionally buyers are able to pick up a cargo of good coal at a low figure. Cars at the local terminals during the first five days of last week ranged from 1,060 cars on May 2 to 1,260 cars on April 29, while dumpings ranged from 174 cars on May 1 to 436 cars on April 30. Some hope is being placed in Lake shipments, many coal men expecting that with the Northwest taking its normal tonnage the Eastern situation will be strengthened.

ened. Local demand has been affected by the dullness in industrial lines in northern New York and New England.

Demand at Philadelphia continues to slip and the end of the slump is not in sight. One of the greatest disappointments is the contract trade. Consumers continue a waiting game, buying blocks of coal in the open market from time to time, with the intention of coming into the spot market again.

Buying at Baltimore is about on the basis that has existed for several weeks past and the offerings to consumers remain about the same also. Scarcity of contracts continues, but the trade feels that as soon as an upward tendency appears in the spot market there will be a move by industries both large and small to get under contract cover for deliveries for the coming autumn and winter.

Dullness is still marked throughout the West Virginia fields, many mines being idle. A few companies manage to obtain short-time contracts, but as a rule there is little spot business to be had. The circular price on smokeless mine run for May has been reduced to \$2 as compared with the April circular price of \$2.25 a ton. High-volatile mines also suffer from marked sluggishness in demand.

Trade in Birmingham has improved none during the past week. Buying is confined largely to lots of a few cars in the spot market and amounts in the total to a comparatively light tonnage.

Strong Demand for Anthracite

Demand for all sizes of anthracite continues strong at New York, although pea coal moved a trifle easier at the end of the week. With output curtailed by numerous local labor troubles throughout the hard-coal fields, operators have no difficulty in moving their product. The last week of April was active for shippers, who were rushed for deliveries on account of the increase in prices which went into effect May 1. All of the large operators as well as most independents added from 10c. to 20c. on all domestic coals, including pea coal in one instance, while one of the companies made its prices for broken 45c. higher than during April. Retail prices were not advanced on May 1. Stove coal continues the shortest of the larger sizes. Egg and chestnut are strong. Steam coals are holding steady and with the output down there is little chance of accumulation.

Cool weather in Philadelphia is keeping up a fair trade for current consumption. Though there has been a general increase in mine prices, dealers have not increased their prices, but it is likely that they will do so when the next monthly advance comes along. Dealers are using these advances in mine prices to encourage consumers to order at once, but the response is only moderate. Increased orders for domestic coal to be stored in cellars for the coming fall and winter has proved an encouragement to Baltimore dealers. There is no rush, but enough business is now developing to keep most of the dealers fairly busy.

Stagnation still prevails in the coke market at Connellsville. Output of beehive coke during the week ended April 26 was 225,000 net tons, according to the Geological Survey, compared with 256,000 net tons during the previous week.

Foreign Market And Export News

Reaction Grips British Coal Markets; Prices and Output Slump

The South Wales coal market is very irregular and somewhat difficult conditions prevail. Under a strike menace the market was buoyed up and prices soared; now that a strike is unlikely a reaction has set in and buyers are holding off. In any case the miners have agreed to remain at work until the findings of the Court of Inquiry become known, and even then a majority by ballot of two-thirds is necessary before a strike can take place. Owing to the superabundance of stocks three collieries have been closed down. The tendency of prices is steadily downward and the outlook is unpromising. Much business is being lost to the United States and Germany.

The Newcastle market is easier, though any available coal is readily disposed of. Most of the collieries are busy overtaking arrears of delivery and many buyers are waiting further developments before placing contracts for heavy delivery during May and June. Several orders from European gas works are being handled in the north of England, the heaviest being in the neighborhood of 6,000 tons.

Coal output by British mines during the week ended April 19, a cable to *Coal Age* states, was 4,994,000 tons, according to official reports. This compares with 5,843,000 tons in the week ended April 12.

French Industrial Demand Holds; Domestic Inquiry Declines

The situation in the French coal market shows little change, demand for industrial fuel holding well, but inquiry for household coal showing a decline since the beginning of the month.

In the regions of France ordinarily dependent upon British fuels there has been an increased demand since the decline of sterling, and with the decline at the shipping docks, since the passing of the strike menace, prices of British fuels in France are more acces-

sible than a month ago. In certain parts of France they work out cheaper, for coke and coking smalls for instance, than some of the German indemnity fuels of corresponding grades.

As the difference in price of British and French coals gets lower, there is less stimulation to purchase home output; even so French collieries are unable to meet all requirements.

Supplies of coke to the O.R.C.A. continue to exceed the level prevailing before the occupation.

The O.R.C.A. statutes will be those of the S.C.O.F. Apportionment of German fuels (coke and coking smalls) to metallurgists will be in proportion to their consumption capacity based on the number of furnaces in blast and not on their capacity of production, as previously arranged. The prices and quantities of coke and smalls bought by the consumers apart from the indemnity fuels also will be considered in apportioning deliveries.

Receipts of indemnity fuels in March totaled 1,001,900 tons, comprising 363,200 tons of coal, 589,900 tons of coke and 57,800 tons of lignite briquets, compared with 808,700 tons in February and 775,900 tons in January last.

Trade Slack at Hampton Roads; Market Tone Weak

Business at Hampton Roads is slack, with demand light, except in bunker trade, where business is fair to good. Coastwise and foreign movement is light, with little increase in this trade in immediate prospect.

Supplies at the piers continue to dwindle, being far below the average, although the supply is equal to demand. Shippers report operations running on reduced schedules or shut down pending a pick-up in the trade.

Prices remain about the same, and the tone of the market is weak. The general impression in the trade is that prices are too low to make good business possible at this time.

News Items From Field and Trade

ALABAMA

Herman V. G. Lwowski, president of the Ruhr section of the Association of German engineers and manager of the Hugo Stinnes Coal Mines at Essen, Ruhr, accompanied by two associates, visited the Birmingham district recently, inspecting the plants of the Alabama Power Co., having come to this country to make a study of hydro-electrical problems.

The Bankhead Coal Co., Bankhead, has opened a new seam at its mine in Jasper, with a daily capacity of 2,000 tons, giving it an output of about 3,000 tons. The company contemplates erecting a five-car tippie at the new opening.

Chicago capitalists owning about 3,000 acres of coal lands near Morris, in the upper part of Jefferson County, inspected the properties recently, and it is understood will commence development of the lands in the near future. The visitors were shown over the properties by Chas. F. Wheelock, a mining engineer, of Birmingham.

The Hercules Powder Co. has begun the construction of its new plant on a tract of 1,280 acres of land recently purchased near Bessemer, which it is estimated will cost about \$300,000 and will have a capacity of 750,000 lb. of explosives monthly, with provisions to double this output if needed. J. J. Grimes is manager of the local branch of the company. The present plant near North Birmingham will be abandoned when the new works are completed.

ARKANSAS

The Paris Coal Basin Mining Co. has been incorporated in Fort Smith with a capital stock of \$25,000. Henry Stroupe is president, and E. H. McCulloch is secretary.

IDAHO

The Oregon Short Line is putting it up to the Teton Coal Mine Co. in a case now before the State Public Utilities Commission. The mining company, which is reopening the old Teton basin mines, wants the commission to order the railroad to repair and operate the nine-mile Short Line branch from Teton Junction to the mines, so that the mining company can ship the possible 500 tons of coal daily which it may produce. The railroad company answers that the repair bill would be \$32,000 and asks the coal company to finance

the work, the railroad to return 2 per cent of the gross transportation revenue of the line for five years. The road contends that the branch was built in 1918 for \$290,433 by order of the U. S. Railroad Administration and that the mines never shipped much coal because of its quality and the fact that the market was and is well supplied from Utah and Wyoming. Therefore it holds that if any further expenditure is to be made on the branch line, the coal company, and not the railroad, ought to assume all liability of loss. The coal company declines, and claims the cost of conditioning the line will be only \$1,000 instead of \$32,000. The commission has not made its decision.

ILLINOIS

The entire sales organization of both the St. Louis and the Chicago offices of the Lake & Export Sales Corporation recently made a trip from Chicago to the Lesco-Scranton mine at Marion, and then to St. Louis. An inspection was made of this mining property, as well as a visit to the Pyramid strip operation, also near Marion, the output of which is handled by the Lesco organization. The party was under the direction of D. S. Gent, president, and W. L. Walton, vice-president of the Lake & Export Sales Corporation.

The Chicago Coke & Coal Corporation, 3,600 Princeton Ave., Chicago, has been incorporated, with a capital of \$100,000, to mine, ship, prepare for market and deal in coal, coke, building materials and products. The incorporators are F. R. Gregg, F. Trilling, George D. Kimball, L. L. Gowan and V. L. Abbey.

Fire about midnight on the 27th destroyed \$65,000 worth of buildings of the Williamson County Mine, near Johnston City, owned by the St. Louis Coal & Iron Co., of St. Louis. All the surface buildings were destroyed except the tippie, which was slightly damaged. It is undecided at this time whether this mine will be reopened at this point. The company is at the present time sinking a shaft east of Johnston City to tap No. 5 vein, and if found satisfactory further development of the property may be worked in this vein. The acreage of the No. 5 vein in these holdings has been practically worked out. This is the oldest operating mine in Williamson County.

Henry Wonder and Thomas Wonder have purchased the mine of the Clift Coal Co., west of Henry, and will operate the business.

The Frisco Railroad contract at St. Louis went to the Indiana & Illinois Coal Corporation for mine run from the central Illinois field at \$1.77, it is reported. The lowest bid on Standard coal was \$1.80, and this coal is graded above Standard. It is understood that the operator really makes more on his coal than \$1.77 on account of a division of rates between the C. & E. I. and the Frisco lines. These mines are located on the C. & E. I. and owned by that railroad. Other contracts recently were the Rock Island, reported for mine run at \$1.78. This tonnage all moves through the St. Louis gateway and the Frisco amounts to 900 tons per day.

The Standard Oil Co. is preparing to resume mining at its Schoper mine at Carlinville. The company has been operating two mines in the vicinity of Carlinville, but will not reopen the Berry mine.

George W. Reed, vice-president in charge of sales for the Peabody Coal Co. of Chicago, is vacationing at Hot Springs, Ark.

The office of the Big Creek Coal Co., at Harrisburg, was destroyed by a fire which swept a business block in that city with total loss of \$150,000.

KANSAS

Thirty days in which to be reinstated in the United Mine Workers was granted miners of the Kansas field who worked during the strike of 1922 and since had not established their union membership, Harry W. Burr, secretary of District No. 14, announced April 28. The dispensation was recommended by a committee from the international board which recently investigated conditions in the district.

Alex Howat has caused another disturbance in Kansas. This deposed district president of the United Mine Workers asserts that the Sheridan Coal Co., which operates in the southwestern district but which does not belong to the operators' association there, offered him \$6,000 a year to become superintendent of its mines. Alex says he refused and declares nobly: "I refused because I am resolved to stay on the miners' side as long as I have anything to do with the mining business in any way. The miners have stood by me through all my fights in the past 22 years and I will stand by them." But both W. F. Megeath, president, and J. E. Megeath, vice-president, of the Sheridan Coal Co. and both of Omaha, Neb., deny they ever offered the job to Howat. They visited Pittsburg recently and were in conference with him.

KENTUCKY

National guardsmen protecting the property of the Liberty Coal & Coke Co., at Straight Creek, were fired upon from the surrounding hills on the night of April 27. After several shots were fired the guardsmen returned the fire with machine guns. So far as known no one was struck. There are about twenty troopers in charge of the plant.

The John P. Gorman Coal Co., Lexington, has purchased the Elk Creek Coal Co. holdings at Blackey, Letcher County, for a reported price of \$400,000. The former owners had their principal office at Knoxville. The mines have a rated capacity of 750 tons daily. The Elk Creek company has Arthur Groves as president; F. F. Floyd, vice-president; both of Knoxville. The Gorman company has a large mine at Fourseam, in the Hazard field.

The Pike Fuel Co., which was recently incorporated in Pikeville, with a capital of \$10,000, has been organized with Willis Staton, president; G. W. Hoskins, secretary and treasurer, and has 150 acres of coal land under development. Present output is 50 tons per day.

Better power is in prospect in southeastern Kentucky as a result of opening the first unit of the new 44,000-hp. steam plant of the Kentucky Utilities Co., at Pineville. The company furnishes most of the power used in both the eastern and western state fields. A high-tension line will connect the Varilla and Pocket plants with the Pineville plant, and also with a new hydroelectric plant, at Dix River, which will be completed within a year.

The Chickasaw Coal Co., recently incorporated in Madisonville, with a capital of \$25,000, has been organized with B. C. Mitchell as president, and is developing 100 acres. The output is to be 150 tons per day.

Coal men of Southeastern Kentucky are much interested in the appointment of Major E. S. Helburn as a member of the Highway Commission of Kentucky by Governor Fields. Major Helburn is the president of the Log Mountain Coal Co., with headquarters at Middlesboro and it is felt that with his intimate knowledge of the needs of the coal-producing districts the long-delayed highway program is in a fair way to be started.

NEW YORK

A device perfected by C. L. Shaw, superintendent of the Lehigh Coal Sales Co., Buffalo, promises to put the small sizes of anthracite into the regular consumer's bin. It consists of a chain, similar in appearance to an automobile wheel chain, intertwined between the teeth of an ordinary triangular furnace grate, which keeps the fine coal from running through the grate. The grates can be operated as usual. A blower and thermostat complete the arrangement and enable any furnace to reduce the cost of coal about \$5 a ton.

All retiring directors of the Maryland Coal Co. were re-elected at the annual meeting of stockholders April

21. At the organization meeting of directors all officers were re-elected.

Public offering was made April 30 at par of \$5,000,000 West Kentucky Coal Co. first mortgage 7 per cent sinking fund gold bonds, Series A, due 1944. The coal company is controlled by the North American Co. The equity over and above the bonds, according to the bankers, is represented by \$6,000,000 of preferred stock and \$7,000,000

J. C. Baker

One of the pioneer mine managers of the Winding Gulf District who has lately become identified with the Newport News Coal Exchange as a field representative in the New River field. He will have his headquarters at Beckley.

of common, the North American Co. having a cash investment in the equity amounting to more than \$6,000,000. The bonds will be secured by a first mortgage on properties appraised in excess of \$11,800,000. A sinking fund of 10c. per ton of coal mined will be used for retirement, the minimum sinking fund requirement being sufficient to retire the entire issue in equal annual instalments by maturity. Net earnings for the six years ended with 1923 averaged \$1,762,438 annually, which is equivalent to about three times the combined interest and minimum sinking fund charges on this issue.

Royal C. Gillespie, formerly with the Eastern Coal & Export Corporation, became associated with the Independent Coal Corporation, New York City, as director, and George H. Pendleton, as assistant to the president, effective May 1.

J. Fred Morlock has taken the Buffalo agency of the Akron Coal Co. of Akron, Ohio, and of the Sunday Creek Coal Co., of Columbus.

Dr. W. S. Blaisdell of Punxsutawney, Pa., who is extensively engaged in bituminous mining in that section, being connected with the Harry Yates interests of Buffalo, has been nominated as the Republican candidate for the Pennsylvania State Senate against heavy opposition.

OHIO

W. J. McFarland has been elected president of the National Coal Co., with mines in the Guernsey and Eastern Ohio fields, succeeding Harry F. Loomis, of Cleveland, who died April 13. Mr. Loomis was president and general manager and Mr. McFarland, who was treasurer, assumes part of his duties, while George J. Kelly, Cambridge, who was general superintendent, succeeds to the general managership.

Lee Llewellyn has been appointed general manager of the Houston Coal Co., Cincinnati, succeeding the late Kuper Hood. Mr. Llewellyn has been connected with Heyl & Patterson and the Pittsburgh Coal Washer Co. for the last twenty years and is regarded as an authority on the preparation and cleaning of coal for the market.

The Southeastern Coal Co., Cincinnati, which was started a little over three years ago by Robert S. Magee and E. L. Moses and has seen various changes in its personnel since that time, liquidated in Cincinnati on May 1. Last fall Mr. Magee, who was president of the Cincinnati Coal Exchange, was forced to go to California for his health and sold out his holdings at that time.

Tow Dew, who was vice-president of the Western Coal Co., Cincinnati, is now connected with the Humphrey Coal Co., of which he has been the secretary since the company was formed.

Walter D. Bledsoe & Co., Cincinnati, have opened a new mine at Martin, where the Elkhorn seam is being tapped. Officials from the Chicago, Indianapolis and Cincinnati offices recently made a trip of inspection.

PENNSYLVANIA

The Bear Ridge Coal Co., operating mines near Frackville and in whose success many Hazleton investors are interested, has started a safety campaign. Signs, "Examine Your Working Place First," are being posted throughout the workings.

The John Mitchell memorial, on the court house square at Scranton, was completed last week and will be formally dedicated May 30, when it is expected that 50,000 miners will parade and addresses will be delivered by labor leaders from all sections of the country. Peter B. Sheridan, of Hazleton, designed the monument.

Officials of District 1, United Mine Workers, are making efforts to avert a threatened outlaw strike of 20,000 Hudson Coal Co. mine workers in the Lackawanna and Wyoming Valley field. The threat of a general strike is made by members of the general grievance committee, who claim grievances are not receiving proper attention.

An explosion of dynamite recently blew up a big tool box at the new No. 6 slope of the Harwood Coal Co., which is being driven from the surface below the baseball grounds in Harwood to reach underlying seams that cannot be located through the operation of other slopes. Ten sticks of dynamite connected by a fuse were found at the mouth of the workings.

Seven miners were saved after a brief entombment May 1 and a total of 107 escaped without injury when fire broke out in the Lee mine of the West End Coal Co., at Mocanaqua. The blaze started in the 240 ft. level. One hundred men in other parts of the mine were taken out the main entry, but seven were caught behind the fire, and the roof caved in, blocking their escape. William Talbot, a foreman, led the men through an abandoned working to the 330 ft. level and then through old workings to the surface. The fire was extinguished after a two-hour fight in the smoke-filled workings, the fan having been stopped when the blaze was discovered.

An opinion by Deputy Attorney General Philip S. Moyer of Pennsylvania, given to Joseph J. Walsh, Secretary of Mines, holds that a bituminous-coal inspector who resigns from office is not entitled to have his name on the eligible list of inspectors on file in the State Department of Mines, and that before he can be reappointed as a coal inspector he must be re-examined in the manner prescribed by law.

Removal of the burning culm bank at the Pennsylvania colliery in Shamokin is progressing rapidly. A big steam shovel is removing the coal refuse between the burned and unburned sections in the hope of keeping the fire from spreading and perhaps igniting one of the near surface veins underlying the bank. The operations are under the supervision of William B. Geise, division engineer of the Susquehanna Collieries Co. The steam shovel will be kept in operation all summer.

Rinaldo Cappellini, president of District No. 1, United Mine Workers, censured employees of the Woodward colliery of the Glen Alden Coal Co., at Edwardsville for calling and maintaining an unauthorized and illegal strike at the workings for five days. The men quit when the president of the local was discharged. The district union president succeeded in having the strike declared off.

James F. Gildea, a prominent mining man, of Plains, Luzerne County, is acting temporarily on the mine examining board until the Luzerne County Court names a man to succeed the late Patrick McGuire, who was killed by an explosion in the Hazleton shaft operations six weeks ago.

UTAH

Utah mines produced 259,585 tons of coal in March, compared with 339,801 in March of last year and 527,606 in March of 1920.

R. M. Magraw, general superintendent of the U. S. Fuel Co. of Salt Lake City, underwent an operation for appendicitis at the Hiawath Hospital last week. His condition is serious. The operation was of an emergency nature.

H. E. Munn, in charge of one of the U. S. Bureau of Mines rescue cars, has become associated with the Utah Copper Co. as coal supervisor.

The new mine of the Black Diamond Fuel Co., at Clear Creek, has reached

the productive stage and coal is now being shipped to Salt Lake City. It is asserted that the coal property of this concern contains 52,000,000 tons of coal. This is one of the new mutual companies.

The final reports on the Castlegate explosion of March 8 show that 171 men lost their lives. Earlier reports set the loss of life at 173.

It is stated that more than half a million dollars will be expended this year in development of Utah coal properties. This estimate is made as a result of leasing activities at the U. S. Land office in Salt Lake City.

R. R. McFall

Who has relinquished the management of the Southern Fuel Co. of Morgantown to become vice-president and general manager of the Universal Fuel Co. of Pittsburgh, Pa.

WEST VIRGINIA

The Gauley Power Co. is planning the construction of two power projects on Gauley River and three on Meadow River, near Gauley and Kanawha Falls, to develop power to operate coal mines which the company is opening up on these rivers.

The La-Go Pocahontas Coal Co. is preparing to begin operations in the near future near Iaeger, the necessary authority having been granted for the installation of a siding. Finishing touches are being put on a large tippie and entries have been driven, so that little remains to be done before the company begins operations. Officers of this concern are H. H. Liggett, of Cincinnati, president; George H. Wise, secretary and treasurer, and C. L. Gaujot, vice-president and general manager. The La-Go company has 1,100 acres under lease and will be able to produce from 600 to 800 tons a day at normal capacity.

L. E. Wood, president of the Central Pocahontas Coal Co., has announced his candidacy for the nomination for the State Senate in the Sixth Senatorial district of West Virginia.

Dan R. Lawson, formerly located at Fairmont, is now connected with the

Philadelphia office of W. A. Marshall & Co., wholesale coal dealers.

The Arlington Coal & Coke Co., of which Morris Watts of Bluefield is general manager, put a new tippie in commission at the Arlington mine last week. This tippie is equipped with modern shaker screens and other equipment for the complete preparation of coal. This makes the third mine recently opened in the same group of interests, the Premier Pocahontas Coal Co. having put up a new tippie a few weeks ago at Premier. A few months ago work was completed for the Gillam Coal & Coke Co.

According to a compilation made by the Pocahontas Operators Association 390,010,346 net tons of coal have been mined in the Mercer and McDowell County fields and approximately 4,287,931,640 net tons remain.

The Weyanoke Coal & Coke Co., of Widemouth, in the Pocahontas field, has just completed work on a new fan for the mine and arrangements are being made to install additional electrical equipment and to re-equip the mine in that respect.

The Coe Pocahontas Coal Co., of McComas, is formulating plans to increase the productive capacity of its mines. The capital stock of the company will be increased from \$200,000 to \$300,000 to finance the project.

CANADA

G. M. Campbell, who has resigned as manager of the Cassidy Collieries, Granby Consolidated Mining, Smelting & Power Co., Ltd., Vancouver Island, was the guest of honor at a banquet March 28, at Nanaimo, B. C., given by the Vancouver Island Branch of the Canadian Institute of Mining & Metallurgy. Charles Graham, of Cumberland, district superintendent of the Canadian Collieries (D) Ltd., was chairman. Nichol Thompson, of Vancouver; T. A. Spruston, of Ladysmith; (Canadian Collieries); John Hunt, Nanaimo, Western Fuel Corporation of Canada; V. Quinn, of Vancouver, Granby Consolidated Co., and J. W. Jensen, Lantzville, Nanoose-Wellington Collieries, who made addresses, expressed regret over Vancouver's loss in the departure of a man of Mr. Campbell's outstanding ability.

A new company headed by A. J. Tonge, former general manager of the Dominion Coal Co., propose to expend \$7,000,000 in the development of the Inverness County coal fields, North Cape Breton, and to control the areas at Mabou, Chimney Corner and Craigness. This development will include the building of a modern town on the banks of the North East River at Cape Mabou, the dredging of Mabou Harbor, the building of a large breakwater, and the putting into commission of a fleet of steamers for the St. Lawrence River trade. The new company intends to compete with the British Empire Steel Corporation for control of the St. Lawrence River business. The deposits of the Inverness basin are estimated at 900,000,000 tons of varying quality suited to any purpose for which bituminous coal can be used.

Traffic News

Through Rate on Virginian to Deepwater Recommended

According to an announcement from Washington, the examining commissioner of the Interstate Commerce Commission has reported favorably upon the petition of certain shippers on the Virginian lines that all-rail through freight rates be established by the Virginian to Deepwater, W. Va.

More than a year ago Major W. P. Tams, Jr., president of the Gulf Smokeless Coal Co., of Tams, W. Va., together with several other operators in the Winding Gulf district, filed a petition with the I. C. C. that the Virginian Ry. be forced to give all-rail through freight rates on coal west so as to relieve the congestion of Virginian coal tonnage at tidewater ports.

The Virginian objected to this request on the ground of a limited number of coal cars and if forced to ship west the road's equipment would be off its rails beyond its control and would be months getting back into the field. Advices from Washington carry the information that the Virginian Ry. will have until May 20 to file objections and argue before the full membership of the commission. It is felt that the Virginian Ry. will continue active objections and that it will take the final decision of the full membership of the I. C. C. to settle the question.

I. C. C. Issues Rate Rulings

Proposed increases in rates on bituminous coal from Green Bay group points in Wisconsin to various destinations have been found by the Interstate Commerce Commission not to be justified.

Certain increases and certain reductions in rates on coal from points in Illinois and Indiana and from St. Louis to various destinations on the Great Northern in Iowa, Minnesota, North Dakota and South Dakota have been found justified.

Rates on coal and coke from Pittsburgh, Connellsville and Reynoldsville to Buffalo are not unreasonable, the commission has found. The relationship between ore and coal rates from lower Lake Erie ports to certain interior points does not result in undue preference or prejudice, the commission has found.

Great Western Disturbs Northwest

Just what the outcome will be of the lower rates on coal from western Kentucky to southeastern Minnesota points via the L. & N. and the C. G. W. remain to be seen. They meet and in some cases cut the low rates made to points on the M. & St. L. Whether this will start something generally remains to be seen. The immediate effect will be to divert some business from southern Illinois to western Kentucky and to cut into the tonnage of eastern Kentucky coal moved off the docks into this district. But if there is not a move in retaliation, it will be strange, and this may start something quite gen-

erally in coal freights, unless it is hindered by some move by the Interstate Commerce Commission. The latter has the subject before it and may not allow the rates to continue, something that seems quite likely in view of the commission's predilection toward averting any serious consideration of the entire subject.

Lignite Rate Hearing Resumed

The hearing on the proposed higher rates on lignite in North Dakota has been resumed at Bismarck, N. D. Representatives from the state railroad and warehouse commissions of South Dakota, Minnesota and North Dakota have presented opposing testimony, indicating the changes would cause increased fuel costs to their respective states. It was estimated that the state institutions of North Dakota, which all burn lignite, would have to pay \$40,000 more a year on coal freight under the proposed rates.

Coming Meetings

National Exposition of Coal Mining Equipment and Machinery of the American Mining Congress, May 12-17, Cincinnati, in conjunction with the annual meeting of the National Coal Association.

West Virginia Coal Association, Annual meeting May 13-17, Cincinnati, Ohio. Secretary, W. H. Cunningham, First National Bank Building, Huntington, W. Va.

National Coal Association, Annual meeting, May 14-16, Cincinnati, Ohio. Executive Secretary, H. L. Gandy, Southern Building, Washington, D. C.

Mine Inspectors Institute of America, Annual meeting, Sinton Hotel, Cincinnati, Ohio, May 14-16. Secretary, Martin Bolt, State House, Springfield.

Retail Coal Dealers Association of Texas, Nineteenth annual convention, May 20 and 21, Vernon, Texas. Secretary, C. R. Goldman, Dallas, Texas.

Pennsylvania Retail Coal Merchants Association, Twentieth annual meeting and exposition, Commercial Museum, 34th and Spruce Sts., Philadelphia, Pa., May 22-23. Secretary, W. M. Bertolet, Reading, Pa.

International Railway Fuel Association, Sixteenth annual convention, May 26-29, Chicago, Ill. Secretary-Treasurer, J. B. Hutchinson, 600 Michigan Ave., Chicago, Ill.

The American Society of Mechanical Engineers, Spring meeting May 26-29, Cleveland, Ohio. Secretary, Calvin W. Rice, 29 West 39th St., New York City.

American Wholesale Coal Association, Annual convention, White Sulphur Springs, W. Va., June 3-4. Secretary, G. H. Merryweather, Chicago Temple Bldg., Chicago, Ill.

West Virginia Coal Mining Institute, Annual meeting June 3 and 4, Elkins, W. Va. Secretary, R. E. Sherwood, Box 1026, Charleston, W. Va.

The National Foreign Trade Convention, June 4-6, Boston, Mass. Secretary, O. K. Davis, 1 Hanover Square, New York City.

National Retail Coal Merchants' Association, Annual meeting, Hotel Virginian, Bluefield, W. Va., June 4-6. Secretary, Walter D. Rogers, Transportation Building, Washington, D. C.

Southwestern Interstate Coal Operators Association, Annual meeting June 10, Kansas City, Mo. General Commissioner, W. L. A. Johnson, Keith & Perry Bldg., Kansas City, Mo.

Illinois & Wisconsin Retail Coal Dealers Association, Annual meeting, June 10-12, Delavan, Wis. Secretary, I. L. Runyan, Great Northern Bldg., Chicago, Ill.

Illinois Mining Institute, Annual meeting, June 12-14 from St. Louis via boat down the river. Secretary, Martin Bolt, Springfield, Ill.

American Society for Testing Materials, Annual meeting, Chalfonte Hotel, Atlantic City, N. J., June 23-27. Secretary, Edgar Marburg, University of Pennsylvania, Philadelphia, Pa.

New Equipment

Improved Lubricating System For Rod Bearings

The Alemite lubricating system, developed by the Bassick Manufacturing Co., Chicago, recently has been adapted to the lubrication of rod bearings. Briefly, the system consists of a large Alemite grease gun which can be quickly applied, without threading, over the end of a nipple, the latter taking the place of the ordinary rod grease-cup plug or cap. These nipples are turned into the grease cups and spot-welded in place so that they cannot work out or be lost, thus saving a considerable item of expense in ordinary operation. This loss is well worth while avoiding, both because of the cost of the caps and, because, and perhaps this is more serious consideration, the loss of a cap gives dirt or grit an opportunity to get into the grease.

The way in which the gun fits over the end of the nipple can be seen in the illustration, as also the powerful gearing arrangement for forcing hard grease through the $\frac{1}{4}$ -in. hole into the grease cup. Pressures up to 2,500 lb. per sq. in. are said to be obtained by turning the long handle which moves the piston through a threaded spindle and gearing arrangement. Friction on the large gear is greatly reduced by means of a ball thrust bearing. The leather and spring in the end of the gun are so designed as to take care of slight irregularities in the nipple ends and to prevent the leakage of grease when the gun is first applied. After

Fig. 1—High-Pressure Grease Gun

A special attachment on the end of the gun prevents any grease from leaking from the fitting. With little effort on the part of the workman 2,500 lb. pressure can be generated to force the grease into the bearing.

Fig. 2—New Nipple Replaces Cap

The shoulder A holds the gun fitting without the necessity of any threading; valve B excludes dirt or other foreign matter. Spring C closes the valve as soon as the pressure of the grease gun is relieved.

pressure is developed in the gun, the leather is held against the nipple with a heavy pressure, and no grease can be forced out except to the grease cup.

Referring to the illustration of the nipple, A is the shoulder over which the grease gun fitting is applied. The valve B and spring are so arranged that hard grease can enter the nipple, but as soon as the pressure is relieved the valve will seat and prevent the entrance of dirt or other foreign matter.

Probably the outstanding advantage of the system is in the better lubrication which it provides. With reasonable care in filling the gun, clean grease can be applied to rod bearings with no danger of cinders, dust and dirt entering with it as too often happens with present methods. Men assigned to the duty of filling rod grease cups do not always realize the importance of keeping the grease clean and even with the best of intentions under present methods the cylindrical sticks of grease often contain dirt picked up when they are laid on the floor or ground. This

newly developed device is designed to prevent foreign matter getting into the grease and eventually to the bearings. It therefore tends to improve the efficiency of rod lubrication and prevent cut and hot bearings.

With the device, the grease cups are said to be filled more quickly than by the usual methods. The grease-gun fitting is simply applied over the end of the nipple and a few turns of the handle will do the work, whereas the

Fig. 3—Auxiliary Portable Gun

Whenever the lubricating system is applied to locomotives or other portable machinery, the engineman carries this gun with him while on the road.

older method requires that the plug or cap be threaded into and out of the grease cup possible several times before sufficient grease can be forced in to fill the cup.

An important safety feature is that should a rod bearing become hot, grease can still be forced into it with the grease gun without the workman being in danger of being scalded with boiling grease. Men are often seriously burned when, in applying grease to a hot bearing, they attempt to thread the plug or cap back into the cup by hand.

Pressure Control Relay

A new pressure governor to be used in conjunction with magnetic starting panels in the control of motor-driven pumps and air compressors, has been developed by the General Electric Co.

The governor can be set for a maximum and minimum range of air or water pressure. An auxiliary relay may be provided which will open the circuit of a control panel when maximum pressure is reached and close it when the pressure drops to the lower limit. The electrical connections are arranged so that the governor merely closes its contacts and is never sub-

Relay Maintains Pressure in Pipes

High- and low-limit contacts by their action hold the air or liquid pressure within predetermined values.

jected to heavy currents and arcs such as develop when circuits are broken.

The contact tips are silver-plated to give low contact resistance and eliminate burning and sticking. The device is enclosed in a cast-iron box with a glass window through which the indicating dial is visible. The complete unit is designed for mounting on a wall. It is approximately 10 in. square and 4 in. deep.

Automatic Limit Switch

An improved device, known as the Ross limit switch, has been placed on the market by the Roberts & Schaefer Co., Chicago, Ill. This small device has been designed for use on electric hoists, using magnetic brakes. It is claimed that it is so connected that it will positively prevent the overwinding of any electrically driven hoist, in the event of failure of any or all of the other control apparatus. It is wired merely between the terminals on the electric control board, and the solenoid-operated brake. Should the drum of the hoist overtravel, the spring switch automatically functions, breaking the current and setting the brake.

Any electrically operated drum hoist can be quickly protected with one of these switches, it being necessary only to tap a $\frac{1}{8}$ -in. hole for the drive pin in the end of the drum shaft.

The switch is designed for an average travel of 128 ft., vertical lift, using a 36-in. drum, but may be applied to any hoist having a shorter lift. Provisions have been made to vary the

Automatic Switch Prevents Overwind

With little expense and labor this little device can be applied as an extra precaution against possible injury to hoisting equipment or men.

adjustment for any particular hoist. For larger hoists the same protective features can be obtained by changes.

Compensated Silent Chain

A simple silent chain possessing many new features has recently been placed on the market by the Ramsey Chain Co., Inc., 1031 Broadway, Albany, N. Y. The section of chain shown in the illustration has had one outside link removed, to show the ends of the pins at the joint.

This joint has a compensating effect when the chain is flexed around a sprocket of comparatively small diameter. It will be noted that the profile of all the pins is the same, producing a symmetrical joint and allowing the chain to run in either direction.

One pin of each pair is carried through the outside links in which it is a drive fit and is spun over after assembly. This method holds the pin in proper relation with the chain at all times. The individual links also are symmetrical, and the simple contour of the holes for the pins facilitates accurate construction of the links. As the relative motion of the pins is rolling, there is no tendency of the faces to slip and groove as they wear, a condition which is also helped by the small angle between the pin faces throughout their action. This chain is now being made in standard pitches from $\frac{3}{8}$ to 1 in. inclusive, and will no doubt be found serviceable for fan drives and coal preparation machinery.

Flexible Steel Chain

As this chain meshes with a sprocket of small diameter, there is a slight increase of the pitch. This compensates for the sudden acceleration impulse which ordinarily strains a chain.

Number 20

The Greater Force

WHICH section of the country will complete the mechanization of the mines first—the union or the non-union? Will the fear of losing markets and the losses in operation so spur the union operators that they will put in conveyors and loading machines? or will the non-union operators out of their plethora of profits, present and accumulated, and out of their shortage of mine labor lead the way? One is disposed to believe that the union men whose needs are greatest but whose financial ability is least will lag behind especially as the union mine workers are not very favorable to a plan which reduces the force of men necessary for the operation of mines.

Rock Dusting Versus Mine Cleaning

IF coal dust is a source of danger in coal mines, why not meet the difficulty by collecting the coal dust rather than by adding rock dust, is a question one frequently hears. No one can seriously question the importance of suppressing coal dust by every possible means, but the main consideration is, how can we reduce the quantity of coal dust so as to reduce the need for using an unnecessarily large quantity of rock dust? For we cannot hope in any coal mine so completely to suppress coal dust that an explosion of any sort will not be extended by what coal dust is present, provided no rock dust is available to render it harmless.

The anxiety to reduce the quantity of coal dust should not be discouraged however. With great care it may be possible to use a maximum amount of rock dust and just have the dust of the mine continue for long periods of time to be of an incombustible character. The devices suggested for collecting coal dust will enable the mine to be prepared for stone dusting without danger. A forcible spray can be used for washing down ribs and timbers, or a vacuum cleaner can be devised for collecting the dust from these places. The dust swept down by the spray can be scraped and swept from the floor and shoveled into cars. The dust collected by vacuum cleaners can be allowed to settle in a container. When the rock dust is distributed it will fall on clean surfaces and consequently will be deposited almost without contamination.

A dry mine with the rock dust thoroughly desiccated may be safer than a wet one, for the rock dust will be ready to rise and extinguish the flame. A wet dust might be disposed to rise in smaller volume with less effect. In any mine the dust on the ribs and timbers will be most dangerous, if the dust of coal, and the most helpful in suppressing an explosion, if the dust of rock. It is likely to be drier and therefore readier to act. In a mine that is properly rock-dusted, it will be cleaner than the dust on the floor, and in one that is not thus treated it will be by reason of its freedom from incombustible material, its dryness, its fineness and its position, the most dangerous dust of any. The rib and

timber dust, small though it is in quantity, is most in need of treatment.

In the Cross Mountain Mine, in Briceville, Tenn., it was noted at the time of the explosion that the coal dust on the floor was of considerable depth, the cars having no end gates. The large quantity of dust, however, probably made little difference, for almost every mine not treated with rock dust or fairly drenched with water can sustain an explosion. Such a little dust is needed that no mine is safe however carefully cleaned, if it is not guarded by rock dust, for the drenching it gets is almost never sufficient for protection.

Missions Worth Supporting

THE movement now well under way in Kansas City for the creating of an active and virile "coal institute" is commendable. Such an organization, if it is backed by the right spirit among coal producers and retailers and if it is manned with men of the right caliber, can go a good way toward setting the public mind aright about coal. Organizations of that sort in most of the large cities of the country can benefit the entire coal industry. But to do this thing, they must sincerely and intelligently aim at real service to the coal consumer of the land as their one and only reason for existing. The benefit to the coal men will follow naturally and deservedly.

There is much service that such an institute can render to a community. Take Kansas City, for instance. Oil competition there is at its keenest. Coal has suffered heavily by that fact. Thousands of coal grates have been replaced by oil burners during the past four years within the district. In some instances, it must fairly be admitted, the change was for the better. It was logical and economical. But in scores of others, the change was bad economy and was made merely because a wave of oil burning was sweeping the community. A coal institute, active and possessed of public confidence could have prevented the shift. It could have so improved the use of coal by prospective oil consumers that coal would have held the market to which it was entitled.

It is a fact that the average household furnace wastes a full 60 per cent of the fuel value of the coal it consumes, partly by reason of bad equipment, partly because of improper maintenance and largely because of plain ignorance on the part of the householder. It is no wonder, therefore, that dissatisfaction with coal is often widespread. Coal consumption in larger heating plants is only a little more efficient and among power plants fuel wastes are tremendous as every well-informed combustion engineer knows. There are things to be done about this. No agency would be in a better position to do them than the community "coal institute." But that institute must be free to do its work in an unbiased, broad-visioned way with the people's interest—not the coal man's—first. Only by that

means can it win public confidence and only with public confidence can it accomplish anything. Its whole object should be merely to give coal a fair chance at the hands of the people. Having done so, it will have established a new and friendlier relation between coal and the public.

Dressed Up and Nowhere to Go

WHY all the insistence in favor of a Department of Mines? Organs are created for the purpose of performing definite functions, but no one has as yet found a function for a Department of Mines. Why reverse beneficent nature and make an organ for which no function has as yet been found? Certain it is that nature will not permit any such anomaly. The department, if formed, will find a function. It will not live in a vacuum. It will have to discover a reason for existence or die. The politician who heads it—and it will be a politician—will find something to do. Will that something be helpful or harmful to the industry? We fear it is most likely to be the latter.

The Department of Agriculture has been a helpful agency for the farmer. It has always been headed by a farmer—usually a real “dirt farmer” at that. The farmers see to that and they are powerful enough to get just what they seek. How long would the head of the department, the Secretary of Agriculture, last if he placed the interest of the public above the interest of the industry? Not a day. He is supposed to clamor and he does clamor for higher prices for the agricultural interests. On the whole the farming industry has a difficult time and needs help. It gets it, however, not because it has a Secretary of Agriculture, but because it controls that Secretary and because it can direct legislation. Farming has a dominant political influence. What is true of farmers and labor is not true of any other groups of individuals.

It is quite likely that a Department of Mines would be a corrective body. It probably would be regarded as the department of correction of the mining industry. It would be headed by someone who was not a mining man. The chairman of the committee on Mines and Mining is quite usually not a mine owner. He is looking after the supposed interests of the public, and he is disposed to believe that this can best be served by a further control of the mining industry. It is likely that this will be true of the Department of Mines if it be formed.

The frogs in the pond, says the classical story, cried for a king. They were tired of being ruled by a log which lay on the edge of the domain in which the frogs lived and croaked. The gods heard the plea of the frogs and sent them a fine outstanding fellow for their king—a long-legged, attractively appareled stork. They were rapt in admiration till presently the stork began to swallow up the denizens of the pond, one by one. Then they began to wish they had not importuned the gods and had been content with the log, which though unsightly and supine, did none of them any harm.

To what end shall we then pray Congress to send us a king? We are told his presence in the Cabinet will give the industry a standing comparable with its importance. Metal men may desire the public to recognize them, but the coal men long ago ceased to tell the public how important they were and how essential to public well-being, for they well know that the people have always a desire to regulate any essential industry and do it by cutting down excessive profits and by ignor-

ing the losses which the mining industry sustains.

The new head of the department would for a while be “all dressed up with no place to go,” but not for long; in a short while he would be regulating every detail of the industry. Mining has suffered already so much that it is to be hoped it will suffer no further interference, except as to increased safety, and that perhaps is best provided by state regulation.

Safe Gas Limits

AT last comes a protest against Professor Wheeler's remarks at Scranton. The correspondent seems almost to suggest that *Coal Age* should have protested against that authority's conclusions and perhaps should not have quoted them.

We are quite willing to say that men should not be allowed to work in a mine for the purpose of getting coal where the content of methane in the return is $4\frac{1}{2}$ per cent. Whether they would be justified in sealing in a fire where such a percentage is found in the return is entirely another matter. In such a case the opening of a door is not so much to be feared as in an operating mine. A sudden outburst of gas is not as likely to occur in such event as in a mine where men are advancing faces. A fall of roof might baffle ventilation. The fan might stop. These contingencies are more remote and in all kinds of fighting—whether against an army or a mine fire—there is some danger.

We thought Deputy Chief Inspector Walker put the matter well when he said it would be his painful duty to enforce the law and have his colleague arrested if he did not withdraw the men where such a percentage was found. Certainly it was well if the professor would seriously try to continue the extraction of coal for commercial use with such a percentage of methane present.

It is customary for the press to quote the sayings of responsible persons as news, even though it does not agree with them. For instance, Republican papers reproduce the speeches of Democratic presidents and other public men. They are not responsible for what is quoted. Nor are Democratic papers subject to criticism for publishing Republican pronouncements.

Some years back we quoted a statement from a reputable German technical journal. This had been quoted in an English Government organ without protest. We gave both publications full credit. That, however, did not save the credit of this journal. It was held that we should have safeguarded our readers by a word of reprobation. We might have done so, feeling the German and British papers were ill-informed on the matter, but thought that such censorship exceeded our duties and that perhaps the German authorities might, after all, be right. The last word has not been said on many subjects.

Some years ago it would have seemed ridiculous, for instance, to use carbon dioxide in the resuscitation of a suffocated man, but close reasoning and experiment have shown that a little of that inert gas stimulates the lungs and, administered with oxygen, greatly increases the rapidity with which the patient is resuscitated. Thus we are always ready to hope that there may be things—good things, of course—“undreamt of in our philosophy,” and if the person making the statement is a competent authority, most gladly do we slide the responsibility for the statement on his willing shoulders. So now we say Professor Wheeler said it, not we. Let Deputy Chief Inspector Walker incarcerate his genial colleague and leave us free and blameless!

Lowering Coal Down Hillsides with Minimum Breakage

Chutes Are Destructive to Coal and Inclined Planes Are Dangerous—Type of Conveyor to Be Chosen Depends Chiefly on Such Factors As Length and Inclination of the Hillside

BY M. L. O'NEALE
Fairmont, W. Va.

THROUGHOUT the Appalachian coal fields a large percentage of the mines have been opened in beds that outcrop on the hills high above the railroad tracks in the valleys. Many of these hillsides are steep, and the problem of lowering the coal from the mine to the tippie, with safety, slight breakage and at reasonable expense, furnishes an interesting study.

Probably the simplest and, from the standpoint of coal degradation, the most extravagant means of getting the coal down the hill is the chute. Where a chute is used, the coal is dumped into it near the level of the pit mouth and runs by gravity to the tippie. The chute must be steep enough to carry damp slack, as well as dry lump. This latter material accordingly accelerates rapidly and in a long chute attains a terrific speed. At the bottom, it is brought to a sudden stop and as a result the breakage is excessive.

Although theoretically a chute may be closed and kept full of coal, a gate being opened at the bottom to draw off the material only as fast as it is dumped in at the top, this is difficult to accomplish in practice. When, however, it is accomplished the coal moves *en masse* and little breakage occurs. The contents, however, are liable to plug, or arch, and may refuse to run unless the chute is made extremely steep. The cost of building a wooden chute in a proper manner also is appreciable. It is difficult to keep tight, and the maintenance cost is high. The sheet-iron plates lining it are subject to rapid wear and must be either excessively thick or must be renewed frequently.

INCLINED PLANE MUCH USED BUT UNSATISFACTORY

Another device frequently used in lowering coal is the gravity or self-acting inclined plane. Here the loaded cars are lowered either singly or in triple by means of a cable and a drum or a figure-eight plane machine. The loads in coming down pull the empties back up the hill, the system requiring no power other than the force of gravity.

This is a fairly simple arrangement, but it has many disadvantages. In the first place, derailments and wrecks are frequent. If the incline is steep, coal rolls from the tops of the cars and litters the tracks. To avoid this spillage, the cars should not be topped as high as is customary where the coal is transported only on light grades. This reduces the tonnage delivered to the tippie per mine car handled. Where under-

ground haulages are long, one of the chief problems of the mine management is to deliver empty cars to the loaders. If the miner is compelled to put 10 to 15 per cent less coal on each car, the daily output of the mine often will be reduced in almost a like proportion.

Because it is designed to round the sharp curves necessary underground, the ordinary mine car is long in comparison with its wheel base. This permits it to seesaw on the incline, so that it is easily derailed by obstructions or inequalities in the track. Consequently a plane of this kind should be well laid with heavy rails and should be kept clean and in good condition, all of which means expense.

More costly and dangerous than a simple derailment is a runaway of one or more cars down the incline.

Fig. 1—An Inclosed Tubular Coal Chute

The chute receives coal from two levels. It is intended to be kept full of coal at all times the contents being drawn off at the bottom only as fast as it is dumped in at the top. This entails little breakage but the chute is liable to plug either from bridging or arching of lumps or from freezing in cold weather.

Fig. 2—Gravity Plane Just Completed

This plane is evidently intended for lowering mine cars as no provision has been made for discharging gunboats at its foot. Lowering the cars themselves entails less first cost but a greater liability to accident from both derailments and runaways.

This may result from broken couplings, defective attachment of the rope to the leading car, failure of the top men to properly couple the trip together, or attach the rope to it, or from other causes. Pushing cars over the knuckle without attaching the rope to them at all is not an infrequent occurrence. An accident of this kind may completely wreck the tippie, cause loss of life and tie up the entire mine operation for a long period. To lessen this danger, safety switches should be installed and their use, by the man responsible for their operation, should be rigidly enforced.

WITH INCLINE, TOO MANY MEN ARE NEEDED

Another objection to this method of handling coal is the fact that a large structure is necessary at the foot of the incline in order to accommodate the empty and loaded trips, as well as to permit of dumping operations. Furthermore—and this is important—a large labor force is requisite to handle the head and tippie ends of such an incline. A considerable saving in labor may be effected by installing a rotary dump at the foot of the plane, which will discharge an entire trip without disengaging it from the rope.

This, however, entails a large investment. With a rotary dump such as has just been suggested, either a storage bin is necessary, which would entail a certain amount of coal breakage and which must be set at such an elevation as to permit a gravity feed to the preparation screens, or the coal must be raised from

the lower portion of the bin to the screens by a conveyor. If coal is to be weighed, as is frequently the case, another problem is introduced. Furthermore, if the mine sends out cars of slate or other refuse, these should be cut out of the trip and their contents dumped from some point on the hill at the top of the incline.

To avoid the difficulties inherent to lowering coal down the hillside in mine cars, the monitor or gunboat plane has been introduced. This obviates some of the evils just mentioned, but introduces others peculiar to itself. To get a large tonnage, the monitor must be of large capacity. Monitors are, therefore, usually built to hold from 6 to 10 tons of coal, depending on the length of the incline and the output of the mine. About one minute should be allowed for loading each monitor and the speed of lowering is determined by the length of the incline, the quality and condition of track and equipment, and the relationship of the grades at the head and foot of the incline. A fair speed is about 10 miles per hour.

MONITORS STAY ON TRACK BETTER THAN CARS

Monitors should be heavily and substantially built. They are of longer wheel base than mine cars, and larger wheels are provided. Consequently they are less readily derailed. They are constructed to suit the inclination of the slope over which they operate and there is much less spillage along the track. Nevertheless, if the incline is steep at the loading point, as it frequently is, lumps very often roll off during the loading process to catapult and ricochet down the slope, endangering the lives of all who may happen to be near the track.

Because of the weight of a monitor and the coal it contains, the track must be substantially built and well maintained. On steep inclines, it must be anchored at intervals to prevent down-hill creep. The rope necessary for monitor operation is heavy and expensive. To prolong its life as well as to prevent the ties from being sawn in two by it, slope rollers should be placed at frequent intervals. These are subject to heavy duty on long inclines, particularly if the slope contains a hump or convex curve. They should therefore be substantially constructed and fitted with good bearings, which should be kept lubricated. Dirt, rock and coal periodically should be cleaned away from them, so as to allow them to revolve freely. If a roller ceases to turn, the rope soon cuts a flat place in it and it is ruined, requiring repair or renewal. The maintenance of track rollers is consequently an item of expense in plane operation, whether monitors or mine cars are used.

As previously stated, however, derailments are far less frequent with monitors than with mine cars. Furthermore, the rope is not disconnected from the monitor except for replacement or resocketing, or for the renewal of connection parts. As a result, if the rope and its connections are carefully inspected, there is small chance for a break-away. Should such an accident occur, however, it is liable to be far more serious than with mine cars, as the monitor is much more likely to hold the track and play havoc with everything at the foot of the plane. Both empty and loaded monitors pull simultaneously against the drum or head sheave, so that it must be made heavy and strong, and securely anchored to a massive foundation.

Loading of monitors is an intermittent operation,

FIG. 3

Belt Conveyor

Belts are excellent means of conveying coal on the level or down slight inclinations. They also may be carried easily over changes of grade. About 18 deg. is the maximum inclination on which a conveyor of this kind may be employed, as on steeper pitches the coal tends to roll on the belt. On grades exceeding about 6 per cent conveyor belts which transport material down hill tend to run away and means must be employed to hold them.

that is, 6 to 10 tons may be taken from the bins every two to three minutes. Accordingly, bins of at least this capacity are required at both the head and foot of the incline. This adds to plant investment and increases both fire hazard and coal degradation. With a monitor plane, coal is subjected to breakage three times—in dumping into the upper bin, discharging from the bin to the monitor and again discharging from the monitor into the lower bin. At the upper end of the incline, the bin is provided with gates for loading the monitors.

These may be automatically opened and closed by the monitors themselves, or they may be manipulated by the drum man, thus saving operating labor. At the lower end, the monitors discharge automatically. If coal is screened, it must be drawn from the lower bin and fed uniformly by a mechanical feeder, in order to secure effective sizing. In many instances, also, in order to obviate a high bin structure and its approach, the coal is elevated from the lower bin gate to the screen.

One other operating disadvantage of the monitor system, and this also applies to the mine-car gravity plane, is worthy of mention, namely, the high maintenance of brake linings on drums or plane machines serving long inclines where the duty is heavy. To reduce excessive wear, a stream of water is sometimes kept playing on the brake band and lining to prevent burning. The solution resorted to by one drum runner—putting oil on the brake band to stop the squeaking—is not to be recommended, as his experiment cost his company some thousands of dollars for cleaning up wreckage and repairing the damage done at the foot of the plane.

To obviate the many disadvantages of the various systems above discussed, the use of conveyors for lowering coal down hillsides is rapidly gaining favor. These devices are gradually displacing the older means employed. The conveyors generally used and those about to be discussed are of four types, namely, the belt, pan, scraper and rope-and-button conveyors.

Belt and pan conveyors differ markedly from the other two types in that the coal is actually carried by them. The force thus resisting material movement is that of rolling friction only, which ordinarily runs from 5 to 7 per cent of the weight carried. This resistance applies both to the moving parts of the con-

veyor and to the coal transported. On the other hand, the scraper and rope-and-button conveyors each drag the coal in a trough, so that the sliding friction of the coal on steel is introduced. This ordinarily ranges from 40 to 50 per cent of the weight.

In the scraper conveyor the steel flights are held clear of the trough, so that the moving parts of the mechanism are subjected to either rolling or sliding friction, which kind of resistance it is, depending on whether the conveyor travels on rollers or slides in steel guides. The friction of the conveyor alone is therefore from 6 to 10 per cent. With the rope-and-button conveyor, the moving parts are subjected to sliding friction—the friction of cast iron on steel—which is about 25 per cent of the weight. These basic differences in the forces resisting the movement of the different types of conveyors determine in a large measure the conditions to which each is best suited.

The belt conveyor is particularly adapted to moderate slopes, or to irregular profiles where a portion of the conveyor is horizontal or even upgrade. The friction resistance is low and the power consumption less than that necessary for the other types. On steep grades this factor has no advantage and, in fact, becomes a detriment because of the braking needed to control

**Fig. 4—Beaded Pan Conveyor**

Conveyors of this kind must be run slower than belt conveyors but by the use of side plates the coal may be piled so deep that their capacity will equal that of a belt. The many links, rollers and wheels employed require frequent lubrication.

the loaded conveyor, unless the installation is big enough to justify the provision of some electrical device to utilize the power generated.

Essentially, the belt conveyor is a high-speed machine as compared with the other types and, without discharging the coal too violently, may be satisfactorily operated at speeds up to 400 ft. per min. At such a speed, however, especially if coal is piled in the center of the belt, it is not adapted to the picking of refuse. This type of conveyor has a long life, is low in upkeep and maintenance, and highly satisfactory in operation. It is, however, costly to install. This is especially true if it handles only small outputs where the width of belt is governed not by the capacity desired, but by the size of the lumps to be carried. At present, the cost of a 36-in. belt conveyor per foot of distance between head and tail pulleys, including the troughing and return idlers but without the supporting structure, will run about \$14 to \$18, depending, of course, on the number of plies in the belt, the thickness of the protecting rubber cover, the brand of the belt, etc. A conveyor of this type and width, however, may be made to carry as much as 400 tons of coal per hour.

veyor would be only about 8 in. Per foot of length between centers of head and tail sprockets, a pan conveyor will generally cost 25 to 50 per cent more than a belt conveyor of the same capacity, provided the belt conveyor does not have to be made excessively wide in order to handle large lumps.

Ordinarily the pan conveyor is carried on rollers placed on a pitch of from 8 to 18 in. For extremely heavy duty, however, this pitch may be increased to 24 in. This construction entails a large number of wearing parts—pins and bushings—that must be lubricated. The rollers, however, move at slow speed and if provided with grease chambers require lubrication at intervals of about three or four weeks. The entire equipment is of rugged design and construction and with proper care its life compares favorably with that of the belt conveyor.

It might appear from the above that a pan conveyor is not as good an investment as a belt. Under certain conditions, however, it possesses some distinct advantages, particularly where the distance between centers is comparatively short. Again, it may be employed to carry coal down much steeper inclines than the belt.

FIG. 5
**Retarding
Conveyor**

This conveyor, like the chute shown in Fig. 1, receives coal at two points. As the coal is dragged along a trough by flights attached to the lower strand of chain this can be easily done without appreciable breakage. Scraper conveyors like this may be made to follow fairly abrupt changes of grade or direction of travel.

The pan (or apron) conveyor consists of overlapping plates or pans attached to steel links which are carried by rollers running on a track or a guideway. This type of conveyor requires a little more power than a belt, but this is no disadvantage in an installation where the grade is over 5 or 6 deg. The pan conveyor is a slow-moving machine and should not be run over 100 ft. per min., and preferably at about 80 ft. per min., the speed depending somewhat upon the pitch of the conveyor chain and the diameter of the sockets. By using high sides on a conveyor of this kind, the coal may be piled upon it and large capacity obtained with comparatively small width even at the slow speed necessary with this type of machine. Because of its slow speed, refuse may be picked from it as it conveys coal to the tippie, particularly if a screen or set of fingers installed at the feed end places the fine coal beneath the lump.

Taking as an illustration the 400 tons per hour mentioned under belt conveyors, a pan conveyor 48 in. wide and traveling 80 ft. per min., would carry this quantity of coal in a bed approximately 11 in. deep. At a speed of 100 ft. per min., the thickness of coal on the con-

veyor is not, as a rule, advisable to install a belt conveyor on an inclination of more than 18 deg., whereas a pan conveyor, particularly of the reverse beaded type, will satisfactorily transport coal down a 30-deg. incline. The pan conveyor also may be carried over sharp vertical curves. A common example of this characteristic of the pan conveyor is seen where it is brought down a steep incline and then broken sharply into a horizontal run to the discharge point on the tippie. Furthermore, as already stated, it may be used for picking refuse from the coal.

The scraper like the pan conveyor is carried on chains. In down-slope installations, however, the rollers are often omitted, either the links themselves or the lugs attached to them sliding along steel guides. Grease may be applied to these guides to reduce friction and wear. The omission of the rollers simplifies the lubrication problem, as the only turning of the pins in their bushings is performed while the chain is passing around the head and tail sprockets. This amounts to only a fraction of a revolution. Like the pan conveyor, this type may be carried over sharp curves.

Because of its greater frictional resistance, this type

of conveyor is better adapted to slopes of from 15 to 35 deg. It may, of course, be used on lesser inclinations, but requires more power which in turn means heavier driving machinery and bigger pins and links. On wide conveyors, or where the drag is heavy, the scraper flights must be strong and well stiffened with angles or heads to prevent bending in the center.

In a conveyor of this kind, the coal is generally carried on the lower strand. For this reason, it can be discharged into chutes without appreciable breakage. It may also be discharged at various points by merely opening or closing slides or valves in the bottom of the trough. In some cases, this is an important consideration as for example, in distributing coal throughout a bin with a minimum of breakage. Degradation of coal in transit is insignificant. As the trough plates wear extremely smooth there is only a small percentage of coal in contact with them and the abrasion is accordingly slight.

Fig. 6—Cross-Section of Pan-Conveyor Gallery

Only comparatively small timbers are necessary in a structure of this kind. As will be noted the largest ones shown in this drawing are 10x10 in. and 8x12 in. The side walkway is not infrequently carried along one side of the conveyor only.

The scraper conveyor travels slowly, generally at from 60 to 80 ft. per minute. It is not, however, adapted to the picking of refuse. Its cost usually ranges between the cost of a belt and that of a pan conveyor. It is difficult to compare the normal life of any of the various types of conveyors, except in a general way, as conditions and the care given the equipment vary materially. Under similar conditions, if the care given these machines is equal, the scraper conveyor should have about the same life as the pan conveyor, except that the trough plate may need renewal before the rest of the equipment, this, of course, depending upon the thickness of the plate used in the first place and the abrasive qualities of the coal handled. Although such conveyors have been installed on inclines 500 to 600 ft. long, they are not well suited to these lengths. This is because of the large number of joints that must be kept up, the size of the links and pins necessary to carry the load and the difficulty of keeping the two strands of chain of equal length.

The rope-and-button conveyor consists of cast-iron

Fig. 7—Cross-Section of a Scraper Conveyor

The construction used in this gallery is quite similar to that shown in Fig. 6. As conveyors of this kind can be made to follow approximately the contour of the hillside timbers in the supporting bents are seldom larger than 6x6 in.

buttons or disks clamped to a steel wire rope, thus forming a single-strand, endless conveyor passing over a sheave at either end. The buttons move in a U-shaped, plate trough, the lower strand as a rule carrying the coal. Head and tail sheaves are provided with pockets spaced according to the pitch of the buttons on the rope. Into these, the buttons drop, the hubs being engaged by the edge of the pocket which serves as a sprocket. The diameter of the sheave is made to suit the size of rope used, which in turn depends upon the stresses encountered in the conveyor line. The sheave at the upper end of the line is made the drive sprocket because of the difficulty encountered in taking up slack in the line if the tail sheave with its take-up bearing were located at the upper end.

This type of conveyor is the simplest and cheapest of the four varieties here considered, provided the length is approximately 150 ft. or more. The higher cost of sheaves and driving machinery forces the price up on short installations. In first cost, the rope, buttons and troughing for both strands will average from \$5 to \$6 per foot of center-to-center distance between head and tail sheaves. To this must be added the cost of the sheaves themselves, together with their shafts,

Fig. 8—Sections of a Rope-and-Button Conveyor

This well illustrates the simplicity of gallery construction. Unlike the other conveyors this type is not well adapted to follow sharp vertical curves. It can be carried however over gradual changes in grade.

Fig. 9—Head Sprocket and Drive, Button Conveyor

Note the rollers on the sides of the button pockets in the driving sprocket. These engage and release the hubs of the buttons without shock or "grabbing." The drive of this type of conveyor is always placed at the upper end.

bearings and driving machinery. Maintenance and upkeep cost is low. The rope is subjected to only slight wear and its life is long.

An improved type of drive sheave places the load on the entering buttons with a minimum of shock, so that breakage of buttons or their slippage along the rope is minimized. Buttons are rarely broken and are cheap to replace should such an accident occur. When a button breaks, however, it does not interfere with the operation of the conveyor, as it is the rim portion that gives way and not the hub. The trough of this conveyor lasts for several years, its life, of course, depending upon the thickness of the steel plate, the tonnage handled per year and the abrasiveness of the material carried. The total tonnage transported over a given trough lining will also depend upon the average loading per hour, as the wear on the lining over any given period of time will be little more when moving 400 tons per hour than when operating at a 200-ton-per-hour capacity.

The labor necessary for operating a conveyor of this kind is a negligible quantity. No lubrication is required on the conveyor line, the head- and foot-sheave bearings and the driving machinery being the only points where lubricant is applied. By means of push-button control, the motor driving the conveyor may be started and stopped at the tippie or head-house as desired, and the feeder drive is ordinarily connected to, and operates in, conjunction with the conveyor drive.

Like the apron and scraper type, the rope-and-button conveyor runs at slow speed, generally about 80 to 100 ft. per minute. It is not particularly well suited for use in picking refuse from the coal, as the material is carried at considerable depth in the trough. At some installations, however, a part of the slate is removed by pickers stationed alongside the conveyor line.

Coal traveling in the lower trough may be discharged with minimum breakage and without spillage by the use of gates in the trough bottom. Discharge may be made at various points, just as with the scraper conveyor. As the coal lies fairly deep in the trough, only a small percentage of it is in contact with the plate. It is therefore transported practically without breakage.

On steel trough plates worn smooth by use, therefore, degradation arising from friction of the coal in contact with the plates is negligible.

The rope-and-button conveyor differs from the apron and scraper types in that it cannot be run over sharp vertical curves. A convex curve or hump adds to the wear and drag of the conveyor, and a concave curve must be so designed that all points in the trough are well above the catenary that the rope and buttons would assume under conditions of maximum stress.

A properly designed concave curve is in reality advantageous, as it tends to equalize the pressure of the buttons on the trough lining throughout the entire length of the conveyor and thereby equalize and reduce the friction and wear. A curve in the conveyor line, however, adds somewhat to the labor cost of erecting the gallery and to the engineering work in both field and office for the trough must be at the proper elevation throughout the bend.

The rope-and-button conveyor finds its greatest field of usefulness on inclinations ranging between 15 and 35 deg., particularly on long conveyors. On moderate slopes, the friction of coal and buttons in the trough increases the power consumption and the tension on the rope. There is, however, no fixed angle under which it may be said that this type of conveyor should not be employed, but the weight of coal handled per hour, the length of conveyor and other factors must be considered. Long installations of this kind have been made embodying vertical curves in which the lower portion of the conveyor even approaches the horizontal.

There is also no fixed maximum inclination beyond which it may be stated definitely that a rope-and-button conveyor is impracticable. On slopes exceeding 35 deg., however, coal lying in the trough above the buttons is liable to roll and flow upon itself. For this reason, it is well to run a steep conveyor at maximum speed.

The ideal condition for a rope-and-button conveyor is to have a slope of about 26 deg. At this inclination, the loaded conveyor is approximately at its point of equilibrium, that is, it is neither consuming nor generating power. This critical angle, however, cannot be fixed definitely, as it will vary with the loading of the

Fig. 10—Tail Sprocket at Conveyor Foot

The cable here traverses a sheave provided with pockets for the reception of the buttons. Takeups are always placed at the foot of the conveyor as otherwise they would be difficult to operate. The head shaft, drive machinery and tail shaft are the only places on a conveyor of this kind that require lubrication.

Fig. 11—Trough, Cable and Buttons

Coal may be piled well above the top of the buttons and yet be transported with ease. When a button breaks it is the rim, not the hub, that gives way. As a result this makes little difference in the operation of the conveyor and repairs may be made when opportunity offers.

conveyor, the physical characteristics of the coal and the condition of the trough lining. Again, a conveyor on a 26-deg. slope may develop power when moving coal at the rate of 400 tons per hour and consume power when operating at the rate of 100 tons per hour.

The capacity of a conveyor of this kind may be extremely large. In fact, on an ideal inclination, no limit can be set, for the coal acted on by the buttons will carry forward the material that is piled in the trough above them. On inclinations greater than 30 deg., the movement of the coal upon itself will cut down the depth to which the conveyor may be safely loaded. This also limits the capacity so that, as previously mentioned, a steep conveyor should be run at maximum speed so as to reduce the volume of coal carried per lineal foot of trough.

Where the inclination of the conveyor is such that

it becomes self acting when loaded, a brake must be provided to absorb the power generated and control the speed of the conveyor. The most satisfactory arrangement of this kind is a brake pulley carried on a counter-shaft mounted in floating bearings. This arrangement allows the pulley to run free of a stationary brake block when the drive is from the motor, but draws the pulley back against the block when the driving power comes from the conveyor. Worm gears also have been used in drives of these machines, and, of course, are arranged so that they lock themselves when the power fails. A solenoid brake may be provided to stop the conveyor in case of power failure, but such a device takes hold suddenly and throws a shock into the conveyor line that may prove damaging. The automatic brake first mentioned takes care of power failure without introducing this sudden shock.

Conveyor galleries are frequently built of wood as the fire hazard entailed by this construction is not as great as that at tippie or headhouse, and their life is fairly long. They may, of course, be constructed of steel, particularly if for topographic reasons long spans between supports are necessary. It also may be advisable to use steel bents and long spans if the hillside is subject to slip and points of solid anchorage are difficult to obtain.

A wooden gallery for the various types of conveyors above described, including a walkway on one side, will require approximately 60 to 75 board feet of lumber above the supporting bents or towers for each foot of conveyor length. Bents are usually so spaced that 16- or 18-ft. stringers may be used. As a result, the load upon any bent is not great and 6x6-in. legs are commonly used, except for high bents. Even if the conveyor is high above the ground, this size of lumber may be used if resort is made to tower construction.

Galleries are usually provided with a walkway along one side of the conveyor only. They may be left open-sided if the climate is not severe, though it is usual to inclose at least one side, ordinarily that next to the conveyor so as to reduce the quantity of rain and snow blowing in upon the belt, chains or cable. The rope-and-button conveyor requires less protection than any of the other types.

FIG. 12

A Long Conveyor

To such conditions as those here shown the rope-and-button conveyor is particularly adapted. The slope of the hillside is almost ideal for this type of installation as a concave curve somewhat flatter than the catenary that the cable and buttons would assume if hanging freely is best suited to reduce friction and equalize wear.

Selecting the Best Type of Motor for Driving a Mine Fan at Variable Speed

Fan Speed Often Decreased at Nights and on Holidays or During Development—Large First Cost Justified When Energy Charge Is High—Motor Should Operate at High Efficiency and Slow Speed

By B. W. CHADBOURNE
General Electric Co.

ELECTRICALLY operated mine fans are usually direct-connected, belt-, gear- or chain-driven. Many years ago most of the fans were belt- or chain-driven, but now fans are frequently directly connected to their motors. This change is due to the extended use of automatic starters, and also to the fact that there is a tendency for a belt to slip off the pulleys when the motor is being brought up to full speed.

At many mines it is necessary to operate fans at constant speed for twenty-four hours per day every day of the week. At other mines the volume of air required varies. A mine in the process of development requires only a small quantity of air but when it has reached an operating stage more ventilation is needed. A non-gaseous mine may require less air during nights and holidays than during working hours. Under these conditions a variable-speed drive is more economical than one that is fixed.

SQUIRREL-CAGE MOTOR IS CHEAP AND EFFICIENT

There are several types of electric motors suitable for driving fans operated at constant speed. Each has some advantages and some disadvantages. When the motor is directly connected to the fan a standard squirrel-cage motor is frequently desirable. It is cheap both as to first cost and operation; it is also simple and the upkeep is small.

The squirrel-cage motor does not operate so success-

fully with a belt drive, because it has a tendency to throw the belt during the acceleration period. For belt drives or for large direct-connected fan units, a wound-rotor induction motor is preferred because with it the acceleration can be made constant.

There are some installations where it is desirable to obtain power-factor correction. This naturally suggests the use of a synchronous motor. A standard-type synchronous motor will not develop sufficient pull-in torque unless the fan is greatly over-motored, therefore it will not bring the fan up to speed unless the airways are closed so as to reduce the load on the motor. This can be done, but it is not desirable to do so. When the power factor needs much correction, an oversize motor can be used, and in that case sufficient pull-in torque can be obtained. This, however, is uneconomical and consequently rarely done. A standard-type motor can be used with a magnetic clutch, but this arrangement is liable to put an excessive stress on the fan.

NEW MOTOR DEVELOPS MAXIMUM TORQUE

To overcome these difficulties the General Electric Co. has developed the super-synchronous motor, which has the stator mounted on bearings so that when the power is applied the stator revolves and soon reaches synchronous speed. The field circuit is then closed, and the motor has synchronous-speed characteristics, that is, it can develop its maximum running torque.

FIG. 1

Adjustable-Speed Mine Fan

This illustration shows a wound-rotor type induction motor driving a mine fan. Seven or eight different speeds are obtainable with this drive.

A brake is then applied to the stator and it is brought to rest, the rotor in the meantime begins to rotate and finally runs at synchronous speed. This motor can be used either belted or directly connected to its load. It is especially suitable for direct connection at slow speeds where an induction motor would have a very low power factor. This equipment is more expensive than the squirrel-cage, wound-rotor or standard-type synchronous motor but it has advantages over any of these drives.

When two or more speeds are required it is possible to use a two- or three-speed squirrel-cage induction motor, a wound-rotor induction motor with a regulating resistance in the secondary circuit, a commutator-type brush-shifting induction motor or a direct-current motor. Data are given in this article by which the cost and overall efficiency of these different kinds of drives can be compared.

As nearly all mines are supplied only with alternating current, it is necessary with a direct-current motor

Fig. 2—Characteristic Curve, Typical Mine Fan

This fan is designed to deliver 200,000 cu.ft. of air per minute against a 4-in. water gage. When operated at this capacity the fan must be driven by a 350-hp. motor.

to have some device to convert alternating to direct current. A direct-current motor with speed control by armature or field resistance could be used, taking power through a rotary converter or alternating-current-direct-current motor-generator set. This would require extra machines and a substation. For the direct-current drive therefore we must consider the use of a separate motor-generator with generator-voltage control.

In order to make the various systems comparable, a particular case has been chosen upon which to base all the calculations, namely a fan which must deliver 200,000 cu.ft. of air per minute against a 4-in. water gage. Incidentally it may be said that the air thus circulated per minute weighs 8 tons or 12,000 tons per day. This work requires a 160-in. fan running at 400 r.p.m. taking 350 hp. For comparative purposes a number of slower operating speeds down to 130 r.p.m. have been chosen arbitrarily.

The results of tests made under the foregoing conditions have been plotted. Fig. 2 shows how the air volume air pressure and horsepower input vary with the fan

Fig. 3—Power Curve of Fan Driven by a Wound-Rotor Induction Motor

It will be noticed from the curves that at slow speeds the power factor of the motor is not good. This is particularly noticeable at speeds less than 200 r.p.m.

speed. In the calculations it has been assumed that the power required to drive a fan varies as the cube of the speed, all openings to the fan remaining fixed.

A wound-motor induction motor rated 350 hp. 400 r.p.m. directly connected to the fan, will meet the requirements. This type of motor complete with drum controller and resistor is simple and will be cheaper than any other drive. It gives seven or eight operating speeds from 130 r.p.m. to 400 r.p.m. and will cost about \$4,700. Fig. 1 shows this type of equipment but with the motor belted to the fan. The power input at various speeds is shown in Fig. 3. The costs given in this and the following paragraphs include boxing, freight for approximately 1,000 miles and installation charges.

Fig. 4—Power Requirements of Three-Speed Induction Motor

The power input, of this type motor is greater at full speed but less at slow speed than for the wound-rotor induction motor. The control equipment is, however, simple.

Another drive which may be considered is a three-speed squirrel-cage motor, which may be rated 18/24/36 poles, 350/197/87.5 hp. and 400/300/200 r.p.m., thus giving three definite speeds at which the fan can be operated. The cost with its control would be \$7,800 or 66 per cent more than for the wound-rotor motor. The power input as compared with the wound-rotor motor installation is higher at full speed but lower at half speed with the inputs identical at about 300 r.p.m. The inputs at the three speeds are shown in Fig. 4.

A commutator type brush-shifting alternating-current motor with a normal rating of 350 hp. at 400 r.p.m. can be operated at any speed down to 130 r.p.m. by shifting the brushes and changing the stator connections from delta to wye. Practically an infinite number of operating speeds are thus made available. Any change in load, such as might be caused by an obstruction in the airway, will have a slight inverse effect on the speed. The complete equipment would cost \$9,400. The power input throughout the speed range is shown in Fig. 5. An installation where this motor was used is illustrated in Fig. 6.

FIRST COST IS HIGHER THAN OTHER SYSTEMS

If a system driven by a direct-current motor controlled by the voltage regulation of a direct-current generator were used this would require a 350-hp., 400-r.p.m. direct-current motor receiving its power from a synchronous motor-driven direct-current generator with exciter. The speed of the motor is controlled by adjusting the strength of the generator field. As it is necessary to buy three machines, the first cost, \$13,200, is higher than for any of the systems under consideration. The power input curve is shown in Fig. 7. At full speed it will be noted that the power input is less

Fig. 5—New Motor Operates at Good Power Factors

The stator of the motor may be connected either wye or delta. By this arrangement it is possible to get a wide speed variation at good power factors. When running near maximum speed the stator winding is connected in delta.

than for either the wound-rotor or the three-speed squirrel-cage motor, but is slightly greater than for the brush-shifting motor. At low speeds its power input is less than that of any of the other types of drives outlined.

There are at least two other methods for driving mine fans at adjustable speed. These are the two-speed wound-rotor induction motor with rheostatic control between the two-fixed speeds and the wound-rotor induction motor with a Scherbius regulating set to control the speed. Both of these systems have a very high first cost and the gain in economy is not large enough to offset it. Therefore, we will not detail the cost or operating characteristics of these two systems.

Table I shows the input in kilowatts and kilovolt-amperes for each of the foregoing types of fan drive.

Table I—Input at Four Speeds With Various Drives

	Wound-Rotor	Three-Speed Squirrel-Cage	Brush-Shifting	D. C. with Gen. Voltage Control

MANY DRIVES USED FOR ADJUSTABLE-SPEED FANS

For mines requiring adjustable-speed fan drives, it is not possible to lay down any general statement as to which method of drive is best, for the reason that no two mines present exactly the same conditions.

We may, however, assume a case in which the fan operates at full speed nine hours per day for 300 days

FIG. 6
Modern Fan Drive

This motor is supplied with automatic speed regulation. The brush-shifting mechanism may be controlled from a push-button or pressure regulator. The control circuit transfer switch is shown on the wall.

Table II—Cost of Operation Per Year With Different Drives

	Wound-Rotor	Three-Speed Squirrel-Cage	Brush-Shifting	D. C. Motor With Gen. Voltage Control
Fixed charge.....	\$710	\$1,170	\$1,410	\$2,000
Power charge, full speed.....	3,850	4,000	4,030	4,450
Power charge, one-half speed.....	2,640	1,460	1,430	1,910
Totals.....	\$7,200	\$6,630	\$6,870	\$8,360

in the year and at half speed the rest of the time. The fixed charge of 15 per cent includes interest, depreciation, etc. There is no penalty considered for the low power factor, and the power cost is taken as a half cent per kilowatt-hour.

Table II, shows that the first cost is not a large item when compared with cost of operation. It also shows that when the operator is not penalized for low power factor, the three-speed squirrel-cage motor is the most economical one to use. However, as this motor has only three operating speeds, it may be necessary to go to the next equipment in order of economy, that is, the brush-shifting motor. If, however, the operator is penalized for low power factor, then the brush-shifting motor or the direct-current equipment would be more economical.

The above data have been compiled not with the expectation that the problem as given would apply exactly to any mine, but to give the underlying principles of operation and with the belief that from the curves and data given, an operator may determine which type of equipment would best fit his particular

Fig. 7—Direct-Current Motor with Generator Voltage Control

This type of drive requires a special generator to supply variable voltage to the fan motor. It is an efficient drive even at slow speeds, but the first cost is usually prohibitive.

needs. These data also have been compiled because there is a growing demand for some better type of drive than the usual wound-rotor motor. In many instances this demand is best met by some type of brush-shifting alternating-current motor.

The Miner’s Torch

As Others See Us

A STATE agent for a large manufacturer of mining machinery had something like this to say on the subject of coal-mining men: “Recently we took on a new line of mine equipment, and, to put our records in shape so that we could give all our customers service and avoid mistakes, we wrote a letter to all the companies who had purchased equipment through the former agent asking that they furnish us with the shop number of the machines that they had in service and also give us the serial number which would allow us to tell the type of machine, as the model had been changed several times. We enclosed a stamped envelope for reply and so worded our letter that all that was required for reply was to insert a few figures and return it.

“We received replies from about one-fourth of the companies addressed. Less than half of the replies were complete and some were incorrect; we had a record of the highest number that had been issued by the manufacturer and thus had a rough check on the numbers sent in. If this information had been of service to us alone, one might have understood the indifference, but the advantage of preventing delays and errors in shipments would react solely to the benefit of the owners of the machines.”

A sales engineer for one of the largest manufacturers of electrical machinery recently told me during a con-

versation that he had come to the conclusion that coal-mining men were inclined to be bigots or fools because they rarely were interested in what their neighbors were doing, and in turn they would not allow their neighbors to find out what they were accomplishing if there was any way to prevent it. Most manufacturers when in the market for machinery welcomed information as to the kind of equipment specified by their competitors, and in order to get an order, a salesman usually had to show photographs of his equipment in operation in neighboring plants and have a list of satisfied customers to whom he could refer. But the coal men generally informed him that their problems differed entirely from those of their neighbors and that the experience of the other fellow could have little bearing on the matter.

A manufacturer of mine cars recently took me into his engineering office and asked me to glance over the drawings he had accumulated covering the mine cars he had built for various coal-mine customers over a period of fifteen years. In all that time he had never built cars for two different customers that were exactly alike; as a matter of fact many of them had individually several different styles of cars in use at a single operation. Dozens of times his salesmen had gone to managers who were preparing plans for new operations and offered to furnish them with prints of mine cars used in nearby operations and although sometimes requests had come in for the prints, he had yet to enter an order that would indicate that use had been made of the information furnished. Once he sent out a circular letter to a number of mine managers asking them to explain how they decided on the wheel base for their mine-car trucks and only 10 per cent replied to the letter.

South Wales Coal Region Is Principal Competitor Of American Mining Districts

Extent and Location of South Wales Coal Fields—Classification of the Different Grades of Coal and Their Uses—Difficulties Experienced in Mining and Marketing of Anthracite

BY HORACE WILLIAMS*

COVERING four counties of South Wales and extending into the County of Monmouth, which is administered legally as a part of England, lies a coal field regarding which the information available has been meager. The coal field has an extreme length of 90 miles and a width that varies from 21 miles in Glamorgan County to about 1½ miles in the County of Pembrokeshire where it extends from Abersychan to St. Bride's Bay and continues for an indefinite distance under the sea. Approximately, this field covers an area of nearly 1,000 sq.mi., including 145 sq.mi. beneath Swansea and Carmarthen Bays.

Almost throughout its extent the coal field is bedded on Millstone Grit, beneath which are Mountain Limestone, Old Red Sandstone and Silurian strata. In the extreme western portion, beyond Swansea Bay, however, the Millstone Grit disappears and the coal lies immediately on the lower Silurian formation. The coal field is practically divided into two elongated troughs by an anticline that extends from Pembrokeshire to a point just east of Pontypridd.

COAL RANGES FROM GAS COAL TO ANTHRACITE

Perhaps the most striking feature of the Welsh coal field is the variety of the kind and quality of the coal produced. The product ranges from bituminous to anthracite. The different classes of coal are described as gas coal, heavy bituminous steam coal, smokeless steam coal, bastard anthracite and anthracite. In the Gower area the principal seams around Llanelly and all the seams east of the line from Gowerton to Neath and Merthyr are more or less bituminous. North and west of that line, the same seams are carbonaceous; in the Aberdare and Rhondda districts, changing gradually to anthracite west of the Vale of Neath.

The coal measures may be assumed to have a total thickness of upwards of 7,000 ft., divided into three principal series, namely, "Upper Pennant," "Lower Pennant" and "White Ash." In the eastern portion of the field there are twenty-six seams having a total thickness of 99 ft., and in the western portion there are eighty-two seams presenting a total thickness of 182 ft. In each instance, however, the thickness of workable coal is much less than that just given. There are approximately 670 collieries, large and small, in South Wales, employing nearly 270,000 men. About four-fifths of the workers are engaged underground and the rest on the surface.

Much can be said regarding the superior quality of the Welsh coal. Experiments made for the purpose of testing the rate of deterioration of the Welsh coal under severe conditions of storage have proved that it does not lose its properties during extended periods. It

Table I—Estimated Tonnage, Percentage and Uses of Different Classes of Welsh Coal

Kind of Fuel	Estimated Tonnage	Per Cent	Uses
Bituminous	8,618,688,965	30.42	Domestic, manufacture gas, coke, etc.
Anthracite	6,310,292,214	22.27	Malting, hop drying, lime burning, gas power, steam raising and domestic use.
Steam (Western Division)	4,076,424,971	14.38	
Semi-bituminous or second-class steam	5,393,724,590	19.04	Stationary engines, bunkering steam vessels.
First-class steam..	3,936,657,410	13.89	Supplying Admiralty.
Total	28,335,788,150	100.00	-

is this quality that has earned for it a reputation of being the best coal in the world. A true anthracite from this field can be stored indefinitely and the briquetted fuel manufactured from the coal loses none of its properties over a long period of years.

An estimate of the contents of the coal field is given in Table I, showing the uses to which each grade or class of coal is best adapted.

The selection by the Admiralty of the coal from the deep mines of the Rhondda Valley for the consumption of the British Navy shows the high esteem in which this coal is held. It has been claimed that this coal enables ships at sea to travel at a higher speed than when supplied with any other coal. That fact, however, does not give the South Wales coal any real monopoly, and the competition between the Cardiff and the Newcastle coals has always been active. It was in the year 1881 that shipments from the Bristol Channel ports first exceeded those from the northeastern ports. In that year the coal exported from the South Wales

South Wales, the Leading Coal Field of the United Kingdom

The principal mining counties are Glamorgan, Monmouth, Carmarthen and Pembrokeshire. Monmouth is markedly Welsh (that is, British) in its population but English in its name and in the administration of its courts. In popular estimation it is a part of Wales.

*Great Western Rwy., Swansea, Glamorganshire, South Wales, England.

district exceeded that from the northern district by a half-million tons.

The development of the coal industry in South Wales and the expansion in its export trade is shown by a comparison of the total tonnage mined and the export shipment for the year 1874, as compared with similar data for the year 1915. In 1874, the mines in South Wales produced 16,000,000 tons of coal, as compared with 57,000,000 tons, in 1915. Again, the exports, in 1874, amounted to 4,000,000 tons, as compared with 30,000,000 tons, in 1915.

In the classification of the South Wales coals as "steam, bituminous and anthracite," given in Table I, it is estimated that the steam coal constitutes between 45 and 50 per cent of the workable seams; the bituminous coal, between 28 and 32 per cent; and the anthracite, between 20 and 24 per cent. The bulk of the steam coal is exported and by far the greater proportion of this is used for marine navigation. For that reason, the South Wales coal holds a leading place among the fuels supplied to ocean steamers at the various coaling ports.

The more bituminous coals, particularly those produced in the Monmouthshire district, are extensively used by railways in the operation of their locomotives. Again, those grades having the highest percentage of volatile matter, amounting in some cases to nearly 30 per cent, are mostly used in the production of gas and the manufacture of byproducts. The anthracite grades are consumed largely in malting, production of gas, cement manufacture and domestic heating. Some of these possess as much as 87 per cent of fixed carbon.

SIXTY COLLIERIES PRODUCE ALL ANTHRACITE

At the present time, the anthracite production is confined to slightly more than 60 collieries, located within a belt of 30 miles. Though a few of the larger collieries produce 700 tons of coal a day, the average output of these mines will range from 200 to 300 tons a day and a number of the smaller mines do not put out more than 50 or 100 tons per day. Until recently, most of the anthracite operations have been confined to drift or slope openings along the outcropping of the seam. All the collieries have grown from small beginnings to their present magnitude.

Today, there are few shafts of any considerable depth but the future expansion of anthracite mining will involve deep shafts and the investment of larger capital. From an annual output of 1,500,000 tons of anthracite thirty years ago, the production has steadily advanced, till in 1923 the production of Welsh anthracite reached 4,333,187 tons, except for a slight diminution during the years of the war.

Until about twenty years ago, the anthracite industry in South Wales was by no means successful and more money was lost than was made in the operation of the mines. In competition with Continental coal, in those early years, South Wales anthracite had to be sold at a low price, and the mines had great difficulty in keeping going. About that time, however, the introduction of what was known as the "Suction Gas-Power Plant" caused an increased demand for anthracite. These plants produced as much power from a ton of anthracite as was obtained by the consumption of ten tons of steam coal burned under a Lancashire boiler. This use of anthracite, in "Suction gas plants," marked the turning point in the history of the South Wales industry.

Yet, looking into the future, anthracite mining in South Wales presents many difficulties. The anthracite seams occur at the base of the coal measures and, being the oldest of the coal formations, are more broken and faulted than the steam coal and bituminous seams which were formed later. Moreover, the anthracite seams are numerous and vary in thickness from a little over a foot to 9 and 10 ft. At present, none of the seams having a thickness less than 30 in. are being worked.

In most of the operations, the roof overlying the coal is difficult to support, and much timber and labor are consumed in cleaning up the frequent roof falls. Faults and minor dislocations are of frequent occurrence, all of which makes the mining of anthracite more expensive than that of other coal. However, with improved mining methods and the introduction of coal-cutting machinery and mechanical conveyors, the thinner seams will be developed.

As is well known, in order to meet the requirements of the anthracite market, this coal when mined must be subjected to elaborate treatment. From the time the coal is loaded at the face and before being shipped, it must undergo a system of mechanical grading, sizing and cleaning by hand-picking and washing, which makes anthracite, in a sense, a manufactured product. By these processes, in South Wales, some thirteen different sizes are produced for various requirements. Swansea is the chief center for the production and marketing of this fuel. From 1894 to 1920 the production has increased from 1½ million to 4½ million tons, owing chiefly to foreign demand, which in 1920 consumed no less than 70 per cent of the output. There are few, if any, coal fields in the United Kingdom better equipped for shipment facilities than that of South Wales. The principal docks are those of Cardiff, Newport, Swansea, Port Talbot and Llanelli, all now under the control of the Great Western Railway Co.

Cement That Matures in 24 Hours

An extremely quick-setting cement is not desirable, but there are many instances where it would be advantageous to use a cement that after the initial set would in a few hours reach its maximum tensile strength. This is especially true in week-end work where operations have to cease unless the cement has hardened before the time for resumption. If the cement will mature in 24 hr. the delay in operation is nil or considerably shortened.

A new product known as Lumnite cement is being manufactured at Northampton, Pa., by the Atlas Aluminate Cement Co., 25 Broadway, New York City. It is said not only to possess the desirable qualities of portland cement but to acquire a strength in 24 hr. somewhat greater than the other kind of cement will attain in 28 days.

A large proportion of high-grade aluminum ore (bauxite) is used in the mixture, and the raw materials are then fused and ground to a considerably greater fineness than is necessary under standard specifications for portland cement. When lumnite is used the mix should be slightly wetter than with portland grades because of the more rapid hydration of the former. The initial setting by this means can be arranged to be no more rapid than with portland cement.

Lumnite cement is somewhat more expensive than portland, and it cannot be mixed with other cements without both losing their distinctive qualities.

Benwood Explosion Shows Need for Stricter and More Uniform Mining Laws

Fire That Followed Blast Quickly Extinguished by Sealing Off—
All-Service Gas Masks Prove More Advantageous Than Oxygen
Apparatus in Rescue Work—Necessity for Rock Dusting Emphasized

BY ROBERT M. LAMBIE

Chief Inspector of Mines, West Virginia

THE necessity for a change in our state mining laws is forcefully brought to our attention by several recent serious explosions. The Castlegate explosion attracted most consideration because more men lost their lives in it than in others and chiefly

The Benwood Mine Was Believed Safe

Too much reliance cannot be placed on the condition of a mine as reported on a bulletin board by firebosses or any other official making an inspection. When the miners entered the Benwood pit mouth April 28 they felt assured of safety, for they saw on the bulletin board the date and the O.K. and initials of the two firebosses. Less than an hour later the explosion occurred.

because its occurrence awakened Utah to the need for drastic revision of and additions to its mining laws.

All attention is now focused on the situation created by the explosion at the Benwood mine, in West Virginia. The industry wants to know the facts—and rightly—relating to the most serious explosion that has taken place in many years in that state.

The explosion in the Benwood mine of the Wheeling Steel Corporation, near Wheeling, W. Va., occurred on Monday, April 28, at 7:08 a.m., taking the lives of 118 men. Not a man in the mine when the explosion took place was able to save himself. Until the examining commission makes its investigation and the inquest is held, no statement can be made fixing the agent of ignition which set off the explosive mediums. However, it is safe to say that a pocket of gas was ignited and the resulting local explosion propagated by coal dust swept all the inner workings and galleries of the mine. The explosion is believed to have originated in Section 9, North.

At irregular intervals this mine, which works the Pittsburgh No. 8 seam, liberates gas at the faces of advancing headings. Nevertheless, it always was con-

sidered safe, though classed as gaseous, and open lights were used by all men with the exception of the firebosses. Dry and dusty sections of the mine were sprinkled by a water car. Both permissible and black powders were used for shooting.

The Benwood mine was opened up about sixty years ago. Its former owners developed it on a two-entry system for a distance of 7,500 ft. from the pit mouth. The present owners developed all its new workings on the three-entry system. Cross entries perpendicular to the mains and butt entries at right angles to the cross entries develop panels in which rooms are driven in two directions on both sides of the butts, which usually is the practice where no pillars are recovered, as in this mine.

EXPLOSION SHOWS VENTILATION INADEQUATE

Up until Feb. 24, 1924, only one intake and one return were provided for ventilation. Realization that better ventilation was needed, when a local explosion last autumn of a pocket of gas in which a fireboss and two other men were killed, led to the sinking of a 9x13-ft. concrete shaft 315 ft. deep. This has an open stairway but no hoisting equipment and it serves as an intake for a part of Section 5, North.

Two firebosses were constantly employed in the Benwood mine, starting their inspections in time to accompany the miners to their working places. On the morning of the explosion the firebosses had made their runs and reported no gas in any section of the mine. A night crew had distributed supplies, including explosives, to all working places in each of the live sections. As was customary, the distribution of supplies was supervised by one of the firebosses.

At 6:30 a.m. two man trips entered the mine. One traveled to Section 5, North, and the other to the main East and 8, North sections. Both trips had reached their destinations before the explosion occurred. The men in Section 5, North, were found a short distance from the trip and apparently were headed for their respective working places, as also were the majority of the men in Section 8, North. Eight men were found in 5 East haulageway in a small trip of mine cars that evidently had been detached from the main man trip and was being hauled by a gathering locomotive.

The men in the main East section had left the man trip and were found some distance away from the trip landing. One of these men was Fireboss Rawlins, who had examined this section of the mine for gas a few hours before the explosion.

The force of the explosion extended to nearly every section of the mine with the exception of an area within a radius of about 1,000 ft. of the airshaft, which is remote from the probable seat of the explosion. Its

Note.—This report was written before the investigation commission of state mine inspectors made its report and before the coroner's inquest was held.

violence was checked at a point on the main entry about 500 ft. from the pit mouth because of the presence of wet spawlings of roof material on the bottom of the entries. Because the explosion spent itself before reaching the outside, no damage was done to the ventilating fan. If the airshaft had not been sunk, or had the violence of the explosion continued unabated to and up the airshaft, it is quite likely that attempts to enter the mine would have been futile, and in that event the Benwood mine with its victims would have been sealed.

All stoppings on the main entry and many on secondary entries were demolished and several overcasts were partly or totally destroyed. That brick stoppings are stronger than those of tile was conclusively proved in this explosion, for the former resisted concussion while the latter collapsed.

The explosion started heavy falls of roof in almost every section of the mine, which hampered exploration work. Practically all timbers were dislodged, releasing heavy loads of roof material on the entries. So weak and treacherous is the roof in this mine that timber sets placed on 2-ft. centers were required on every principal entry. A 6-in. bed of roof coal is left in mining, above which is an easily weathered soapstone 4 to 10 ft. thick.

HEAVY FALLS ARE MENACE TO RESCUERS

Many difficulties were encountered which obstructed the rescue and exploration work to recover the bodies of the victims. Heavy falls on the main entry extended from the point where the explosion spent itself, 500 ft. from the pit mouth, in by for thousands of feet, obstructing an entry into the inner workings of the mine through the drift opening. A rescue team, on advancing 4,500 ft. from the pit mouth by crawling over the falls was forced to give up the attempt. In the evening of the first day activities were transferred from the pit-mouth side of the mine to the Browns Run airshaft.

In order to maintain a larger volume of fresh air in the workings being explored, the system of ventilation was changed. The intake of the split ventilating that area nearest to the pit-mouth side of the mine was stopped after two of the temporary stoppings erected in the early exploration were removed. This intake then aided the regular return airway in conducting air to the exhaust fan.

The change increased the flow of fresh air down the airshaft from 17,000 to 27,800 cu.ft. per minute and served, wherever the ventilation was effective, to draw all gases away from the shaft. The volume of fresh air entering the shaft was increased hourly as temporary stoppings were erected to guide the ventilation. Incidentally, the water gage reading of 7 in. is a measure of the damage done by the explosion in destroying ventilation and obstructing airways by bringing down roof.

Browns Run airshaft is reached by traveling over a country mud road for about 3 miles from a hard state road. A heavy rain throughout the first day made the mud road impassable for trucks; therefore wagons, sleds and tractors were used in transporting supplies to the shaft. As no hoisting equipment had been installed in the shaft, supplies had to be lowered by a rope attached to an improvised cage platform, passing over a pulley block fastened to a hastily erected wooden headframe, and drawn by horses. Later a tractor was pressed into service for raising and lowering the cage.

Rescue men were compelled to use the stairs in entering and leaving the mine.

As an aftermath of the explosion, a fire broke out on a pillar between rooms No. 3 and 5 off 19 East heading. The roof in the vicinity of the fire fell heavily due to the high temperatures developed. The fire was discovered following an investigation subsequent to the night shift's complaints of headaches and the discovery of such manifestations of underground fires as "breathing" action.

Little time was required to extinguish the fire by sealing off the fire zone. An air lock was erected to allow the passage of men into the fire zone after the fire was believed to have been extinguished. After a search in this zone for bodies, it was sealed for the second time. The situation was precarious because of gas about 1,000 ft. from the fire, a fireboss patrol being required at all times to protect the men exploring the mine.

Scene at the Shaft on the Day of the Explosion

The shaft has an open stairway but no hoisting equipment and serves as an intake for a part of Section 5, North.

The cause of the fire is not known, though the theory is advanced that a heavy squeeze on a room pillar caused spontaneous combustion. If the fire started before the explosion it may have been responsible for the latter. There are no manifestations of violence in the fire zone; consequently the explosion did not originate in this area.

The Benwood explosion, like several others of less serious consequences, should emphasize the necessity for classifying all mines as gaseous that liberate any quantity of gas. To avoid similar disasters, those mines which rightly should be termed gaseous must use approved electric cap lamps and explosion-proof motors and also permissible explosives.

The advantage in practicability of the Burrell all-service gas mask over self-contained oxygen-breathing apparatus in rescue and exploration work following an explosion was conclusively proved at the Benwood mine. At least fifty masks were in use at all times and about 90 per cent of the work was done by men wearing them. However, the self-contained oxygen-breathing apparatus was used to explore places where it was thought the percentage of oxygen in the air was not sufficient to support life. The latter equipment also was worn by men who accompanied the gas-mask crews, to act in cases of emergency. In only rare instances was the heavy and cumbersome outfit really required. Men

wearing the gas mask penetrated as far as 125 ft. beyond points at which the carbon monoxide content of the air killed canaries.

How much greater are the freedom of movement and efficiency in the work of the wearers of gas masks was demonstrated to H. Foster Bain, Director of the U. S. Bureau of Mines, who spent a long time in this mine, wearing a gas mask himself and watching the rapid erection of stoppings, the recovery of bodies and other work by men equipped with the mask. In many cases, with cars jammed across the tracks and with timbers knocked crosswise and interlocked, it would have been exceedingly difficult to work with self-contained oxygen-breathing apparatus.

Mine rescue stations, in my judgment, are not complete unless equipped with at least ten gas masks.

Of the men who lost their lives in the Benwood explosion I am certain that the two men who were first found would have saved themselves had they carried a self-rescuer (diminutive gas mask). Evidence surrounding the finding of at least 35 bodies proved that these men were not killed by the violence of the explosion. As it was, many of these men tied handkerchiefs around their noses and mouths in an attempt to ward off death by the breathing of afterdamp. Had they also been equipped with self-rescuers, and not been prevented from reaching the outside by falls, they, too, would have been saved.

WILL URGE WEST VIRGINIA TO ADOPT ROCK DUSTING

There remains one more point about which I desire to speak, and that is the necessity for rock dusting to prevent the propagation of explosions. It is my intention to use every resource at my command to urge the operators of West Virginia to take this important step in the direction of safety.

The criticisms which appear in this report are not directed in particular toward any company, field, district or state. Accidents of small or large magnitude cannot be attributed directly to carelessness or neglect on the part of a mine or company manager. Before state mine departments can effectively place responsibility for accidents and fatalities they must build a structure of mine laws that provides no loopholes for evasion. The present laws must be brought up to date in order to meet with the requirements of our fast-growing industry and guard lives and property under conditions brought about by advanced methods of engineering and operation. To that end coal-producing states should combine in an effort to make uniformity of mine laws a major consideration.

It is high time that an interstate code of safe-practice regulations be formulated, to which individual states so far as possible should adhere, in a sweeping movement to revise and extend the scope of mine laws. There are many ramifications to the achievement of the purpose for which we should strive, but in sum and substance our biggest task is the attainment of uniformity in the mine laws of states in each competitive region. When this is accomplished, all operations in each of the several competitive regions will be placed on a plane of equality in regard to the monetary cost of obeying the mine laws in their respective states.

There is yet another phase of our prospective program which must not be overlooked. That is the education of the consumer of coal in the importance of safety in mining. He must be made to realize that the cost item resulting from the employment of safety precau-

tions must be absorbed in the price of a ton of coal; also that safety can be obtained only by the use of permissible equipment, which is more expensive than that which is not approved, and safety devices of various kinds. All these increase the cost of coal. If only the consumer paid for these items, as he should, and in periods of depression such as we are experiencing now, cost cutting were not applied to anything that guarantees safety!

Benwood Blast Due to Ignition Of Gas and Dust by Open Lamp

Inquest Proves That No Mine Working Pittsburgh No. 8 Seam Is Safe Without Closed Lamps and Rock Dusting

FOLLOWING the presentation of evidence lasting all day relative to practices before and conditions after the Benwood mine explosion, at the coroner's inquest held in Benwood, W. Va., on May 10, the jury returned the following verdict: "That one George W. Holliday, Jr., and others came to their death in an explosion on the 28th day of April, 1924, in a coal mine located in the City of Benwood and owned by the Wheeling Steel Corporation, said explosion being caused by the ignition of an accumulation of gases combined with coal dust, by an open miner's lamp."

Such were the facts brought out in the hearing as told by all witnesses who knew the conditions as they might have existed at the point of origin before the explosion and as they did exist after. Though a fire was discovered in the mine during the exploration work, the evidence proved that even if it had started before the explosion, it was not responsible for the ignition of the gas which caused the latter.

Practically all the testimony coming from state inspectors, company officials and other men who helped in restoration of ventilation and the recovery of bodies proves almost conclusively that the explosion originated in No. 4 room on 9 East off 9 North. In this room a fall of 8 ft. of roof occurred about 20 ft. from the face.

This fall probably occurred after the fireboss' examination on the morning of the explosion. When roof falls in the Pittsburgh No. 8 seam under heavy cover it is likely to liberate gas soon after. This is what

Muddy Roads Impassable to Trucks but Not Tractors

This is an example of the difficulties experienced in getting supplies to the Browns Run airshaft.

certainly must have happened. The miner who was supposed to work in this room most likely approached the fall and then either climbed over or around it, setting off the gas. His body was hurled from the face of the room to the entry.

No. 4 room is driven in about 100 ft. from the entry and is connected with rooms No. 3 and 5 by means of breakthroughs, in accordance with the mine law requiring that the latter be turned every 80 ft. Carbonization on the inby side of timbers and distinctive coking of ribs enabled the investigators to trace the path of the explosion from the fall near the face of No. 4 room out to the entry, and also through the breakthroughs to right and left to No. 3 and 5 rooms respectively and thence to the butt entry and through every part of the mine.

Interrogation of all witnesses who were familiar with the ventilating fan dispelled the rumor that the latter was shut down on Sunday. It had not been shut down for nearly two months prior to the explosion, and then only for about 20 minutes on a Sunday while brushes were being adjusted in the motor. Another rumor to the effect that one J. T. Boyle, who really laid track, was permitted to act as fireboss was as readily disproved.

MINE, THOUGH GASEOUS, NOT THOUGHT DANGEROUS

George W. Gehres, superintendent of the Benwood mine, admitted that gas is given off from time to time at faces in advancing headings and also accumulates in cavities formed by the fall of roof, but, he said, that this mine, though gaseous, was never considered dangerous. Barometric readings were taken daily and firebosses were conscientious in their work. Mr. Gehres believes the explosion occurred somewhere on the right side of the 9 North heading between 9 and 14 East because this section of the mine is the "hottest." He said that the mine is naturally dry; coal dust had to be loaded out regularly and the entries sprinkled frequently.

Jerome Pyle, fireboss, who examined places in the 5 North section in the morning of and prior to the explosion, admitted that his duties were not confined to firebossing alone; that in addition to his regular duties he supervised the distribution of supplies by a crew of two men on the night shift. He never left his own territory, however, and the supply men with open lights entered places to distribute supplies only after he had examined for gas and general safety.

The first of the two supply men on the night shift, Sam Buzinski, in reply to a question by Chief Lambie as to the occurrence of coal dust, said: "Yes, lots of dust; pretty dry on main line." He also remarked to the effect that the air was sluggish on 5 East entry on Sunday night. He reported this fact to the fireboss.

Paul Rijak, the second supply man on the night shift, admitted the presence of some dust on the entries. He substantiated his companion's remark that the air was slow on 5 East entry, due to a fall on 6 East.

Fred Christini testified that his duties were that of a patrolman, having to make his rounds on the off shift, going into all places but those abandoned, for the purpose of watching for fires, bad roof and timbers.

Browns Run Airshaft at Benwood Mine of the Wheeling Steel Corporation

This concrete airshaft, which is 315 ft. deep, was completed only recently. It was the only opening through which the rescuers could enter the workings after the recent explosion. A wooden stairway in this shaft, fortunately, was undamaged by the explosion, being in a downcast. It aided the rescue men in their work. Bodies were raised and supplies lowered on a box or cage attached to a hemp rope which passed over a pulley block and was drawn by a caterpillar tractor.

He also was instructed to keep section switches of the power lines open.

D. M. Ryan, an operator who directed the work of getting supplies into the mine and who many years ago went through an explosion, gave his opinion as to the origin and cause of the explosion. He said that an idiosyncrasy of the Pittsburgh No. 8 seam in the Panhandle region is the release of roof gas, which accumulates in a cavity formed by a fall of roof. This accumulation may occur soon or a long time after a fall.

Because the rails in the 9 East heading off 9 North are badly twisted and other indications of great violence are found on this entry, he feels reasonably sure that it was the origin of the explosion. In answer to a question by Mr. Lambie as to the possibility of a fall of roof between the time the fireboss inspected No. 4 room and the time a miner might have reached the face to start work, Mr. Ryan said that that probably is what occurred. The miner, seeing the fall and thinking it had been examined by the fireboss, probably started to skirt or go over the fall with an open light on his cap, igniting the gas which quickly accumulates.

Several other witnesses admitted that an accumulation of gas following a fall could form after a fireboss had made his examination and before the day shift came on duty. They admitted that roof gas liberated by falls was treacherous. Falls of roof in the Pittsburgh No. 8 seam under heavy cover generally release such gas. For that reason approved electric cap lamps are really needed though seldom used.

Andy Boyce, a motorman who missed work on the day of the explosion, said that 9 and 10 East headings, on which the explosion is said to have occurred, usually are wet at the face. W. D. Lee, state inspector, however, said that the mine is dusty soon after sprinkling. Victor E. Sullivan, another state inspector, said the Benwood mine is the driest mine he has ever entered.

James Gibson, mining engineer of the Wheeling Steel Corporation, answered a number of questions by Robert M. Lambie which brought out the fact that the Browns Run airshaft was not in full-capacity use at the time of the explosion. A rearrangement of the courses of the air would have required the building of many stoppings, etc. These were being rushed and probably would have been completed in three weeks from the day the explosion took place. Two men found near the air shaft were stone masons.

Mill Yard from Which Entrance Is Gained to Benwood Mine, the Scene of the Recent Mine Explosion

The drift mouth is located just within this fence, and the main entries pass under the street. Little damage was done to the surface buildings by the force of the explosion. The main entries were obstructed by heavy falls.

The fact was also brought out that the distance between the Main East headings and the head of 8 and 9 North headings off the former is about 1,800 ft. In that distance the rise is about 15 ft. in the direction of the faces of 8 and 9 North entries. That means that gas is more likely to accumulate in this section than in any other part of the mine. He voiced the opinion that coal dust played no small part in the explosion.

Superintendent Gehres, again called to the stand, said that six certificate bosses were employed in the Benwood mine. Drop-bottom cars of a type that do not close in a tight fit were used and resulted in much spillage of slack along the haulageways. Coal dust was shoveled out at regular intervals. As much as 50 cars of dust had been loaded out in one clean-up. Sprinkling was resorted to when and where necessary with no fixed method or schedule. Mr. Gehres believes that a local explosion which killed three men last autumn occurred in 10 East off 7 North, which point is about 400 ft. from the origin of the recent explosion.

R. W. McCausland, general superintendent of mines

of the Wheeling Steel Corporation, is satisfied that the explosion started in the room designated by previous witnesses. He said that he received weekly reports in which the fact was noted that coal dust was being loaded out of the mine. He said that prior to the explosion he had no knowledge of the methods and frequency of sprinkling. When Mr. Lambie asked Mr. McCausland what had ignited the gas causing the explosion, he answered: "Open lights."

A. E. Lafferty, of the state, who inspected the mine two months ago, stated that as far as he was able to ascertain the mine was in good condition then.

All the recommendations which his department made, though costly, were being followed by the company. "A safe condition can be changed in a week; in an hour," said he. He also called attention to the fact that between 5 and 7 o'clock on the morning of the explosion barometer readings showed a fall of about $\frac{1}{2}$ in. Such a decided fall usually causes a greater liberation of gas than otherwise would escape from faces, roof or clay veins in the Pittsburgh No. 8 seam.

The inquest proves that no mine working the Pittsburgh No. 8 seam (and for that matter any other seam) is safe, comparatively speaking, unless closed lamps and rock dust are used. Any mine working the Pittsburgh No. 8 seam that is under heavy cover, if open lamps are used in it, may be the scene of an explosion today, tomorrow or any time. It is safer to play with dynamite than to work such mines with open lights. Chief Lambie recommended approved closed lights and rock dusting in this mine, and hopes that the time is near when these two precautions will be taken in every mine in West Virginia.

Low-Temperature Carbonization of Coal

OF ALL ways of using coal the most wasteful of all is to burn it. We are learning that slowly. Just when we were making up our minds that coking with saving of byproducts was a better way and had learned how to do it satisfactorily, word came that it should not be coked, it should be only charred, giving more light oil, a better domestic fuel and with certain briquetting and high temperature carbonization even a better metallurgical fuel than straight coke. Unfortunately, though we have learned how much better it is to char coal and what we would get from it by charring instead of coking, it would be an untrue assumption to declare that we have learned how to do it economically.

An English book entitled "Low Temperature Carbonisation of Bituminous Coal," written by Andrew McCulloch and Neville Simpkin and published by H. F. and G. Witherby, of 326 High Holborn, London, W. C. 1, explains quite adequately what has been done hitherto. Despite the fact that it says nothing of the Piron system, which Henry Ford has made prominent, it is extremely complete and truly international.

It must be remembered that England has made notable progress early and late, in low-temperature carbonization, notably in the Coalite, Maclaurin, L. M. N.

(Laing, Marshall and Nielson), Pure Coal Briquette, Del Monte, Chiswick, Fuel Research, Freeman, Turner and Illingworth processes. All these are described in this volume with some that have been devised in Continental Europe.

The work of American chemists is scantily recognized, little reference being made to the division into resinic and humic sulphur which has engaged the investigatory powers of Powell and Parr. It is true their inquiries into the character of organic sulphurs is purely scientific. As yet they have led us nowhere but it cannot be safely overlooked for at any time they may open a way to a more perfect technique of coal treatment.

Some general remarks follow on the general problems of low-temperature carbonization and a lengthy reference is made to the many processes available. The final two chapters are on coal tar and low-temperature tar. An appendix details the specifications for British fuel oil, benzol motor-fuel oil, tar and pitch for roads and for grouting and the requirements of the German Tar Distillers' Federation for Diesel-engine oil. Another gives much information on coke structure and combustibility with many interesting illustrations of the former. A good bibliography concludes the book.

News Of the Industry

Farrington Urges Co-operation of Miners With Operators to Cut Output Cost

Sees Only Hope for Illinois Mines in Checking Inroad of
Non-Union Competition—Thinks Nationalization of Mines
Unlikely—Outlines Advantages of Giant Power Plan

Peoria, Ill., May 13.—Establishment of giant power plants in Illinois was suggested as a possible way of improving and stabilizing the coal industry, by Frank Farrington, president of the Illinois United Mines Workers, in opening the biennial convention of Illinois miners here today. He also bespoke co-operation with the operators to cheapen the cost of producing Illinois coal, in order to check the inroads of non-union competition and provide work for union miners.

Unemployment, which has already overtaken 30,000 Illinois miners, was shown by Mr. Farrington to dwarf all other problems almost to insignificance. He dismissed the threatened attack on his appointive powers by an appeal to the reasonableness of the members, declaring it was not a political asset but an obstacle to any scheme he might have to form a "machine."

Outstanding features of his report were his suggestions for solution of the problem of unemployment, though he also devoted some attention to the matter of out-of-work benefits. He urged that the convention declare in unequivocal language either for or against such payments and draft rules in accordance with its decision.

Cheap Production Paramount

"The bituminous-coal industry is highly competitive," said Farrington, "and under free competition, all other things being equal, that producer will secure the market who can produce the cheapest. From this it follows that any increase in the cost of production of coal in our district will result in increased competition from the unorganized field."

"As a matter of fact this competition has already reached a proportion which has become a serious menace to the life of our organization and the coal industry of Illinois as well. The widespread unemployment we have experienced of late in the Illinois field is due largely to the competition of Kentucky and West Virginia coal, which is underselling Illinois coal in the Chicago market. It also may be mentioned that had it not been for the shopmen's strike which seriously crippled the coal-carrying roads during our late suspension, the influx of non-union coal might easily have been fatal to our organization."

"The remedy for the competition of non-union coal would be, of course, the unionization of the unorganized fields. But while we all hope that some day these fields may be as strongly organized as our own district, we cannot blink at the unpleasant fact that all attempts in that direction have met with such tremendous obstacles as to make them more or less futile."

"In the face of such conditions it will become increasingly difficult to obtain the improvements in wages and working conditions to which our members are justly entitled. In other words, we find ourselves in the position where every increase in wages and lowering of hours of labor is followed by a reduction of production in the organized fields for the benefit of the unorganized fields. And if we follow this tendency to its logical sequence we may imagine a situation when our wages and conditions are so favorable as to put an end to the coal industry of Illinois."

"In view of the unsatisfactory status of the coal industry, three successive conventions of the U. M. W. A. have adopted resolutions contemplating the nationalization of coal mines. Without going into the merits or demerits of the plan suggested by our committee, let me state that the decentralized character of our government would make it exceedingly difficult to bring about the nationalization of mines, even if such a policy were found feasible and desirable."

"Fortunately we are so situated that the coal industry of Illinois may be organized on a new basis without waiting for the consent of two-thirds of the states of the Union."

"Such a reorganization would imply the creation of:

"(1) A semi-public corporation in which District No. 12, the operators, the consumers and the state would be represented, so as to safeguard the interests of all these factions."

"(2) The establishment of one or more giant power plants on the Ohio and Mississippi rivers for the manufacture of electricity."

"(3) An integrated network of major and minor power lines to make electricity available to every hamlet and farmhouse in the state."

"(4) The distillation of coal at or

Coal Miners May Pick Strawberries

The closing of the Consolidation Coal Co. mines at Seaboard, Va., throwing about 130 men out of work, has added considerably to the task of the Public Employment Service, recently inaugurated by the General Assembly to take care of such situations.

J. Hopkins Hall, State Labor Commissioner, calls attention to the fact that labor will soon be needed to harvest the strawberry crop and it has been suggested that idle miners be sent to the strawberry fields. Mr. Hall says that this would be "a happy solution" of the difficulty.

near the giant power stations, in order to save the byproducts of coal, which are now wasted.

"The benefits anticipated from the plan suggested are: (1) An increased demand for Illinois coal through (a) the substitution of electric light for kerosene light; (b) the substitution of electric power for gasoline power; (c) the substitution of electric stoves for wood, oil, gasoline and crude-oil burning stoves; (d) the more extensive use of electrical labor-saving devices in home and farm, such as washing machines, vacuum cleaners, corn shredders, etc.; (e) the illumination of concrete highways; (f) the substitution of artificial anthracite for fuel oil in heating plants."

Looks for Many Benefits

"Other benefits anticipated are:

"(2) A marked reduction in the price of light, heat and power at the expense of water in transportation, selling and delivery."

"(3) The stimulation of industry by a steady supply of light, heat and power at reasonable prices."

"(4) The abolition of the smoke nuisance."

"(5) Cheaper fertilizer for the reclamation of land."

"(6) Steady employment for our members."

"The plan as sketched herein must be merely regarded as a suggestion."

"Sooner or later the welfare of our country, as well as that of the coal industry, upon which the well-being of our members is dependent, will require a profound change in the mining, distribution and utilization of coal."

"And as there is no other body of our citizenship more vitally interested in the coal industry than we who bear its burden, I request that this conven-

tion empower the executive board of District No. 12, United Mine Workers, to employ the funds of the organization for the purpose of obtaining the necessary advice to ascertain the practicability and desirability of the plan suggested herein.

Nearly 100,000 Miners in Illinois

"According to the records of the Department of Mines and Minerals we have a total of 374 shipping mines in Illinois. During the fiscal year ended June 30, 1923, an average of 99,081 men were employed. The mines worked an average of 146 days, or less than half time, and produced a total of 73,410,837 tons. This means that Illinois mines have a potential producing capacity of 150,000,000 tons annually. During approximately this same period, West Virginia, with about the same number of men employed, mined 103,000,000 tons, or nearly 30,000,000 tons more than was mined in Illinois.

"The great bulk of the West Virginia tonnage was mined under non-union conditions at 1917 wage rates and much of it at rates lower than the 1917 rates. In fact in Mingo, Logan and McDowell counties, in southern West Virginia, where the bulk of the non-union tonnage was produced, the miners are paid 90c. for loading a four-ton mine car and the highest inside day wage rate is \$4 per day.

"In Alabama, Kentucky and Tennessee the situation is relatively the same as in West Virginia, excepting that in some parts of Kentucky the wages are higher than in West Virginia, but nowhere in Kentucky are wages as high as in Illinois, while in Alabama the wage rates are lower even than in West Virginia.

"Considering that Illinois coal must find a market in competition with coal mined in the states named the situation furnishes a problem for some very sober consideration on the part of the Illinois mine workers. Last winter we had less work than during any winter period within my recollection and this summer promises less work than ever before and hunger and want is now present in the homes of thousands of our members.

A careful tabulation of the situation reveals that on the first day of this month 150 Illinois mines were completely closed, and many of them had been closed for months, with no im-

mediate prospect of resuming operations and every indication is that as time advances more mines will suspend work. When these 150 mines were in operation they gave more or less employment to 30,000 of our members, and fully that number of men are now idle. Very few of the mines that are now operating are working more than half time and the great majority of them are not working that much.

"I hold no brief for the Illinois operators, but I do for the Illinois miners and my only desire is to help the miners, but in order to do that I must help the operators find a wider market for their coal. Without markets there can be no work. The consumer will get his coal where he can buy it the cheapest.

"The mining industry is fully 50 per cent overdeveloped, which means there is an abundant supply from which the consumer may choose, and the competition for markets is, therefore, desperately keen and consequently the operator who can sell his coal the cheapest will get the business that means work for the miners. Therefore, there is only one way whereby we can get more work for Illinois and that is to cheapen the cost of producing coal in competition with coal mines in non-union and sparsely organized districts where the cost of production is much less than in Illinois.

"I do not mean that I would have the Illinois miners accept a reduction in wages or give up any beneficial working condition. That would not help, for the reason that if wages were reduced the operators in competing fields would do likewise and the effect would be that all would be in relatively the same position only on a lower level, but there are means by which the cost of production may be reduced and without injury to the miners, but with profit to them in the way of more work.

"Respect your contracts, eliminate strikes in violation of contract, work when the operator has work to do, do careful workmanship, load clean coal, reduce the amount of slack by careful shooting, give an honest day's work, co-operate with the management in doing the things that are right, fight for what is coming to you, but do not antagonize, and be on the square. All these things will tend to reduce the cost of production and bring more work to Illinois and relieve some of the distress that is among us."

Reliance-Hatfield Coal Cos. Are Merged

The Reliance Coal & Coke Co. and the Hatfield Coal Co., including the E. J. Hickey Transportation Co., Plymouth Coal & Mining Co., Inc.; the West Virginia Washed Coal Co. and the Licking Valley Coal Digger Co., have been merged into one unit after having operated separately, some of them over a quarter of a century, and in conjunction with each other as part of the Fleischmann interests in Cincinnati, Kentucky and West Virginia, along the Kanawha and Ohio rivers.

The combined unit, which will be known as the Hatfield-Reliance Co., will own in fee simple 6,444 acres of coal deposits and will have under favorable long-time lease 5,513 acres additional, estimated to contain more than 65,000,000 tons of recoverable coal in West Virginia and eastern Kentucky. The company will operate four mines most modernly equipped, together with controlled mines and mining interests in the two states, and also holds control of stocks in many retail coal companies in Louisville, Carrollton and Maysville, Ky., and New Albany, Madison and Vevay, Ind., and in other river communities along the Ohio. The properties are appraised at \$3,151,952.94, but are carried on the books of the new company at \$2,532,368.66, around 80 per cent of appraisal. Julius Fleischmann will be president, J. T. Hatfield be vice-president, Irvin Davis secretary-treasurer, August Helm assistant secretary and F. J. Ed Bramlage assistant treasurer of the company.

Name Hard-Coal Advisers to Commerce Department

The anthracite operators have designated the following representatives of the anthracite industry to serve as members of the advisory committee to the Coal Division of the Department of Commerce: S. B. Thorne, president, Thorne-Neale & Co., 17 Battery Place, New York City; G. N. Wilson, president, Lehigh Valley Coal Sales Co., 90 West Street, New York; Howard W. Perrin, vice-president, Susquehanna Collieries Co., Commercial Trust Building, Philadelphia.

Retrenchment Policy Seen as Menace To Co-operative Effort by Coal Industry

Statistical Data More Necessary Than Ever During Period of Stress
—Funds Needed for National Association's Bureau of Economics
Program—Unusual Responsibilities Confront New Administration

BY PAUL WOOTON
Washington Correspondent of *Coal Age*

One of the unfortunate effects of the retrenchment which is going on among the coal producers is the weakening of the industry's organizations. Local associations are weakening, and the National Coal Association is suffering seriously.

Despite the discouraging circumstances which surround the coal trade at the time the National association is holding its annual meeting, it is believed that one of the effects of this gathering will be toward the prevention of allowing retrenchment to go to the point where it will undermine the industry's statistical foundation and deprive it of its one means of doing the constructive things which can be accomplished only through co-operation.

Disintegration among the local associations might proceed so far as to break down the structures necessary to collective bargaining. This did happen in 1893, when the coal business was in a situation quite similar to that which apparently is impending at this time.

Association Work Needed Now

It is important to the industry and to the public that co-operation, as represented by the activities of the local associations and by the national association, should go forward. The way out of many of the present difficulties lies in joint effort. The association is the only device on the operators' side through which joint effort can be carried out. Instead of shutting down statistical work and curtailing other activities, the associations, during a time of stress, should be working harder than ever. They should be given the means to capitalize the prevailing feeling of dissatisfaction with present conditions to get something better. If coal producers are to act intelligently in their own welfare and in the public welfare they must function as a unit in meeting a variety of situations.

The National association should be given the funds necessary to put through the broad program of its Bureau of Coal Economics. In addition to the information which that bureau would collect and interpret, the National should be in a position to stage a comprehensive drive for membership. It should be more representative of the industry. As it is, it frequently is looked upon as a non-union association. If for any reason local associations cannot be induced to affiliate with it, every effort should be made to obtain the maximum possible number of individual members in that district.

The administration which will pilot the National association through the next year is faced by unusual responsibilities, but its prospect of success is unusually bright if it will adopt an

active and determined policy looking to the lining up of the industry for the common good. It is either that or simply the drawing out of the process of falling to pieces.

There are many who hope that the new administration will address itself to the task of putting in more concrete form the objectives of the industry. What should be done to meet its difficulties? How can better public relations be established? What is the policy of the industry in the matter of co-operative marketing? Do coal producers want the Sherman anti-trust law amended and in what particulars? How can contracts be improved?

These and a hundred other suggestions could be made to make up a definite program of the objectives for which coal producers are striving. In addition, it is hoped that something can be done to raise the morale among coal producers. They have the enthusiasm and the spirit necessary; all that is required is to direct it in association channels. They should be impressed with the need of showing the same loyalty to their organizations that the mine workers show to theirs. The coal digger is willing to stick to his union even if it means going hungry and undergoing all manner of sacrifices. More of that spirit is needed among the operators. The foregoing are some of the thoughts which are being expressed as the operators are assembling for their principal gathering of the year.

Official Washington has its eye on Cincinnati. This convention is looked upon as something of a turning point in the affairs of the producers of coal. It is regarded as certain to indicate whether they are going to present a solid front in this crisis or whether they will disband and try to meet their difficulties in a disorganized way.

Russian Coal Output Higher

Gross coal output during the first quarter of 1923-24 (October to December) by the Russian coal basins of Donetz, Moscow, Ural, Kuzbas and Cheremkhov was 211,214,000 poods (a pood is equal to 36.113 lb.), compared with 144,349,000 poods during the corresponding period of the previous year, a gain of 46.4 per cent. The net output was 174,673,000 poods, compared with 103,349,000 poods for a similar period in the preceding year, an increase of 69 per cent. The greater increase in net output is due to a reduction in allotments to the miners.

Production was higher in all fields, but the increase was especially marked in the Donetz Basin, where the gross output for the quarter was 62.9 per cent greater than for the corresponding period of the previous year.

Exports from the five basins during the above period were 133,842,000 poods, compared with 108,517,000 poods for the first quarter in the preceding year, a gain of 23.3 per cent.

On Oct. 1 last there were 602 coal-mine enterprises employing 168,293 workers under the management of the Supreme Council of National Economy. Of these, 35 enterprises employing 37,842 workers were united in trusts and syndicates.

Production in the Maritime Province (Eastern Siberia) at the end of the business year 1922-23 was 90 per cent higher than the prewar output. The principal mines, those of Suchan and Zygun, which are operated by the government, produced 22,000,000 poods of coal, while the privately operated mines produced 16,000,000 poods. The selling price of brown coal is identical with that prevailing before the war.

Coal Mine at British Empire Exhibition

Top works as seen from the entrance to the mine, at Wembley, Wales. A comprehensive collection of cutting machines and other mining equipment also forms a part of the display.

Coal Men Hear Talk of Taxes, Trade Groups And Government Control at Cleveland

Paul Armitage, Goldthwaite H. Dorr and James R. Garfield Try to Rouse Them to Dangers of Overtaxation, Weakness of Trade Associations and Waste of Resources

An attempt was made at Cleveland, Ohio, by the United States Chamber of Commerce, in annual session May 6-8, to make coal-mining men realize that they are in the same boat with other operators of natural resources and that there ought to be a pooling of effort in mutual defence. Paul Armitage talked about present overtaxation of mining, urging active campaigns against it; Goldthwaite H. Dorr, legal staff man last year for the Bituminous Coal Operators' Special Committee, argued for strong trade associations, and James R. Garfield one-time Secretary of the Interior, defended the government policy of control over natural resources.

A number of coal men were present at some of the Chamber sessions, registering a voice in the traffic group for a resolution urging Congress to postpone for a year Sec. 28 of the Transportation Act in the hope that coal exports abroad will not be interfered with by the act. If Sec. 28 goes into effect next month, as the act provides, it will require all coal destined for export to use American bottoms during all periods when the U. S. Shipping Board says there are plenty of American ships available. If such coal is consigned to foreign bottoms, it will move from mines to piers under the domestic freight rates, which are much higher than those on export coal.

National Coal Men Attend

Among the coal men present was this delegation to represent the National Coal Association: Louis Madeira, 3d, Madeira, Hill & Co., Philadelphia, Pa.; J. R. Crowe, president of the Crowe Coal Co. Kansas City, Mo.; Monro B. Lanier, Monro-Warrior Coal & Coke Co., Birmingham, Ala.; Michael Gallagher, Wheeling & Lake Erie Coal & Mining Co., Cleveland; S. H. Robbins, Progress Coal Co., Cleveland; H. R. Sullivan, Central Coal Mining Co., Cleveland, and Allan H. Willett, statistician for the National Coal Association, Washington, D. C.

A wallop at the Ford proposal for the purchase of Muscle Shoals was dealt right lustily by Mr. Garfield. The former Secretary of the Interior took time from his main discourse to declare that turning Muscle Shoals over to Ford would be deliberately depriving the people of the great South of vast power service to which they are entitled under the government policy as to the disposal of natural resources. He said the potential development is about 800,000 hp., but that Mr. Ford agrees to devote only 100,000 to the manufacture of fertilizer for the farmers while he keeps the rest for himself.

"That's why I'm against Ford," said Mr. Garfield. "The plan as accepted by the House at Washington permits him to selfishly keep most of the resources of the development for himself. The

government should control all such water powers and lease rights in them only upon such terms as will permit the people of the entire distribution area to be served. That is the principle behind government control of any natural resource."

He said that the people of this country had really waked up to the necessity for conservation only within the past quarter of a century. The anthracite men have always known pretty well what the anthracite resources of the land were because the deposit was so small and so definitely described; but nobody knew much about the extent and probable "lifetime" of bituminous coal. The awakening, however, has now produced a different feeling on the part of the people toward their coal, their oil, their timber and the other natural resources.

Early Efforts Misunderstood

The government's early efforts at conservation were much misunderstood. Owners of great stands of timber couldn't see at first why they should not do as they pleased with it, and power interests that had been farsighted enough to reach out and grab many good watersheds for future use felt the same way. But most such interests have come around to the government's position that all the people, not a favored few, should benefit by the resources, and future generations are as much entitled to the possible benefits as this generation.

That is the reason, he said, that men permitted to operate public coal lands now readily agree that they should use the deposit so as to safeguard the interests of all the people. When that isn't done voluntarily the government is obliged to step in and see that it is done compulsorily.

The mining industries of the country should begin organized efforts at once to educate the people, the legislatures and the courts of the land, said Mr. Armitage, well-known tax expert, so as to offset the tendency to overtaxation. He said such a tendency these days is strong enough to be a real menace, as evidenced by the Minnesota iron and Arizona copper cases, now well known, where mining is taxed and supertaxed and overlaid with layer after layer of special taxes so that it groans under the burden.

The mines, the oil and gas deposits and the timber of the land are basic resources. It is unthinkable what would happen to industry if the output of these industries were cut off. Every man, woman and child would be affected at once. Yet, he said, legislatures gayly toss outrageously heavy tax burdens upon such industries with no thought of the way they are striking at the rest of their country's whole industrial structure.

For one thing, he said, law makers

and law interpreters should be taught that depletion and loss incident to production is an allowance that ought to be permitted for capital cost and should be deducted before taxation. A Supreme Court decision a few years ago denied the reasonableness of this, he said, but the decision was based on nothing short of plain ignorance. Today the tide is turning and he thinks if the point were to be raised again before the Supreme Court, the previous decision would be reversed. There remains a great deal of educational work to be done, however.

He contended that the opening of new mining deposits to replace worked-out areas ought to be regarded as discoveries and should not be penalized by taxation. Up to 1918 they were treated as excess profits, but today a more reasonable attitude is taken. He pleaded for smaller taxes or no taxes at all upon mining reserves. A study showed that a 3-per cent tax on a certain metal reserve deposit, if continued for 30 years, would bleed the owners of the entire value of the deposit. However, most states try to tax reserve coal and ore.

Mr. Armitage complained bitterly about government extravagance and wastefulness, saying he doubted whether the present administration could possibly reduce taxes at the rate expenditures are running. He thinks his proposed tax-reducing organization in the mining industries could profitably devote a good deal of time trying to reduce government waste, extending itself even to the point of carrying out government enterprises so as to get the work done at reasonable cost.

Attacks Anthracite Tax

He cited a long list of special taxes, like the Pennsylvania 1½ per cent anthracite tax, which have been levied within the last few years, mentioning the effort Congressman Kellar of Minnesota is now making at Washington to get a straight 1 per cent tax laid upon the entire coal and metal deposits of the country so as to raise \$650,000,000 a year for Congress to spend.

The "natural heritage of the people" argument, upon which such taxes of coal and ore are defended, he attacked as fallacious reasoning. Men open the mining deposits of the country by great expenditure and risk of capital and the application of much labor and inventiveness. Without these expenditures the deposits would be worthless. Therefore the "natural heritage" argument for the taxation of these deposits is illogical.

It is easy to tax mines because they are always within reach and cannot get away. Also absentee ownership of many of them makes them especially tempting targets. This is so true, he said, that today the public is plundering these resources by taxation. This and the public ownership propaganda ought, he thinks, to wake up the whole mining industry to its danger so that it will defend itself more effectively.

At the close of the Chamber session by the division of natural resources production, a resolution was adopted protesting against the compulsory reporting to the government of any sort of statistics on ordinary business operations.

Hoover Says Trade Associationism Is Saving Coal Industry from Itself

Tells U. S. Chamber of Commerce That This Idea Is What Gave Steady Running Time in 1923 and the Three-Year Agreement

—No Call Now for U. S. Control of Coal

The trade-association idea has already done a great deal for bituminous coal and can do a great deal more, Herbert Hoover, Secretary of Commerce, told the U. S. Chamber of Commerce at its Cleveland convention May 7. It was that very idea, practiced jointly by coal and railway associations and the Department of Commerce, that caused wide buying of coal last summer, thus preventing the troublesome annual drop in production in the hot months. It was the same idea at work, he said, which produced the three-year contract at Jacksonville, thus giving the industry some promise of stability for that period.

He said the development of proper trade-association work convinces him there lies within such associations "a great moving impulse toward betterment." He implied that this is exactly the sort of thing that will answer the one-time loud demand for government control of business. He does not believe that "today there is any sentiment for government regulation of the bituminous-coal industry."

Commerce Department Co-operates

"I propose now to mention a case most vitally important, rendered possible only through associational activity in which the Department of Commerce has been in active co-operation," said Mr. Hoover. "That is in the bituminous-coal industry. There have been developed in this industry, as many of you are aware, 30 per cent too many mines operating intermittently during nearly every week of the year with a large seasonal dip in summer. Thus they required 30 per cent more labor and 30 per cent more capital than was necessary to produce the nation's coal.

"One effect of this situation was that some proportion of the employees obtained too few days' work to yield them a reasonable standard of living, even at the apparently high daily wage. This minority of employees were naturally a constant source of agitation and disturbance. The result of all this was a higher cost of producing coal and consequently a higher national coal bill; speculation and uncertainty to the operators; hardship, difficulty and instability to a considerable portion of the workers.

"The fundamental cause was a vicious cycle of seasonal fluctuation in demand, annual shortages in coal cars, and periodic strikes which grew out of the instability of labor relationships. These periods of shortened or suspended production always resulted in famine prices for coal and great stimulation to the opening of new mines.

"At least four government commissions have examined this question. Probably forty bills have been introduced into Congress proposing govern-

mental regulation in an attempt to correct the abuses and wastes and public danger that lay in the situation.

"The associational agencies in the field were those of the operators, of labor, of the railway executives and of the various associations of industries as consumers. The first problem was to obtain a general knowledge of the causes, to which I feel the Department of Commerce contributed substantially. Remedy was undertaken in many directions. The railway association induced the construction of a more ample supply of coal cars and greater expedition and interchange in handling between different railways. The Department of Commerce, in co-operation with the Chambers of Commerce, manufacturers' associations, railway and public utilities associations, effected the placement of more coal in storage during the summer season. The result was that last year for the first time in many years we had no interruption in the distribution of coal due to car shortages. One element of the vicious cycle in this situation is eliminated, provided we can continue this same co-operation in future.

"The second part of the solution was the general agreement by both operators and labor that stability could not be restored in the industry unless there was a long period of continuous operation in which the absence of coal famines and profiteering would eliminate the speculative and high-cost producer and reduce the units in the industry and thus its intermittency. The labor agreement between these associations made last February for a term of three years has assured this improvement.

"Here we have an example of the

most profound national importance in at least the beginning of stabilization of an industry involved in a most vicious cycle of waste and trouble. The national savings can be measured in hundreds of millions and the human hardships greatly lessened. There will be some preliminary hardship in so great a self-imposed surgical operation, but I am confident it will heal to the mutual interest of the operators, the public, and the workers. Today I do not believe there is any sentiment for government regulation of the bituminous-coal industry.

"Three years of study and intimate contact with associations of economic groups, whether in production, distribution, labor or finance, convince me that there lies within them a great moving impulse toward betterment. If these organizations accept as their primary purpose the lifting of standards, if they will co-operate for voluntary enforcement of high standards, we shall have proceeded far along the road of elimination of government from business. American business is never secure unless it has public confidence behind it. Otherwise it will always be a prey to demagoguery and filled with discouragement.

"The test of our whole economic and social system is its capacity to cure its own abuses. New abuses and new relationships to the public interest will occur as long as we continue to progress. If we are to be wholly dependent upon government to cure these abuses we shall by this very method have created an enlarged and deadening abuse through the extension of bureaucracy and the clumsy and incapable handling of delicate economic forces.

"The government can best contribute toward the day-to-day progress of business life through stimulation of and co-operation with voluntary forces in our national life, for we thus preserve the foundations upon which we have progressed so far—the initiative of our people. With vision and devotion these voluntary forces can accomplish more for America than any spread of the hand of government."

Barge Convoy Ready to Help Fuel New York

This fleet of barges, belonging to the U. S. Distributing Corporation, awaits a trainload of coal at one of the New Jersey rail terminals at Edgewater, N. J., opposite New York City.

Buy Coal Now, Says Hoover Letter to Trade Bodies

Herbert Hoover, Secretary of Commerce, addressed a letter May 10 to secretaries of trade associations asking their support in urging manufacturers to begin buying and storing coal now in order to avert car shortage and transportation congestion next autumn. The letter in part is as follows:

"The fall car shortage always has the effect of increasing the price of coal and of seriously disturbing the whole economic machine. Security lies in repeating the storage performance of last year, by the manufacturers of the country taking reserves of coal during the months of May, June and July, thus foregoing the necessity of coal shipments during the peak period in competition with the household movement. Outside of strike years, these months are universally the period of lowest bituminous-coal prices.

"We also have a national problem in the long view of securing cheaper coal by maintaining more regularity in production of our mines through planing out seasonal fluctuations.

"I therefore ask that your association actively interest itself in bringing these matters to the attention of the large coal consumers from the point of view of their personal interest as well as a contribution to the mutual good of American business."

Shipping Board Opens Bids At New York

Seventeen coal firms submitted bids to the U. S. Shipping Board at New York on Monday, May 12, for furnishing and delivering not more than 18,000 gross tons monthly of navy standard coal for use on vessels of the board operated from New York Harbor. The deliveries are to extend over a period of one year. The bids follow:

J. H. Weaver & Co., \$6.05 f.a.s.; Quemahoning Coal Co., \$5.25 f.a.s.; Willard, Sutherland & Co., \$6.60 t.i.b., \$5.95 f.a.s.; Independent Coal Corporation, \$6.33 t.i.b., \$5.60 f.a.s.; Eastern Fuel Co., \$6.21 t.i.b. over top bunkers, \$6.41 t.i.b. through side bunkers, \$5.81 f.a.s.; Seiler Coal Co., \$6.66 t.i.b., \$5.61 f.a.s.; Horgan Fuel Corporation, \$5.23 f.a.s.; Steamship Fuel Corporation, \$6.31 t.i.b., \$5.51 f.a.s.; Imperial Coal Corporation, \$5.90 f.a.s.; Cosgrove & Co., \$6.82 t.i.b. over all bunkers, \$7.02 t.i.b. through side bunkers, \$6.02 f.a.s.; Coleman & Co., \$5.51 f.a.s.; Dexter & Carpenter, Inc., \$5.74 f.a.s.; H. B. W. Haff, \$5.93 alongside, 10,000 tons monthly; W. A. Marshall & Co., \$6.65 t.i.b. over all bunkers, \$6.85 t.i.b. through side bunkers, \$5.99 f.a.s.; Commercial Coal Co., \$6.12 f.a.s.; Pennsylvania Coal & Coke Corporation, \$5.68 f.a.s.; Johnstown Coal & Coke Co., \$5.17 f.a.s.; E. Russell Norton, \$7.05 t.i.b., \$6.99 t.i.b. freight ships.

Timely Topics on Tapis at Wholesalers Convention

When the American Wholesale Coal Association holds its annual convention at White Sulphur Springs, W. Va., June 3 and 4, between 400 and 500 wholesalers from all parts of the country will be in attendance. The committee in charge of arrangements has so arranged the program that the business sessions will convene at 9:30 a.m. and adjourn at 1 p.m., leaving ample time for recreation.

The business sessions of the convention will be of great interest and importance to all those connected with the coal industry. Realizing that the conditions facing the coal trade today are different from any with which they have ever before had to contend, the discussions will be along lines calculated to solve some of these difficulties and to build a constructive platform for the future.

Among the speakers will be F. R. Wadleigh, of the Tuttle Corporation, New York, and former Federal Fuel Distributor, who will present for consideration a plan looking to close co-ordination between the various branches of the industry. E. M. Platt, president of the Platt & Brahm Coal Co., Chicago, will discuss "Costs and Credits." "Oil Competition" will be handled by Borden Covell, president of the Northern Coal Co., Boston, Mass. "Transportation and Its Relation to the Coal Trades" will be the subject of a paper by G. N. Snider, for many years coal traffic manager of the New York Central Lines and more recently general manager of Dickson & Eddy, New York. "The Wholesaler of the Future" will be the subject of an address by Owen Meredith Fox, associate editor of *Black Diamond*, Chicago.

Other features will be announced as the program is completed. These subjects alone insure wide interest and discussion of the problems before the convention. Everyone connected with the coal industry in any way and particularly wholesalers, irrespective of membership in the association, are urged to be present and to assist in solving the problems confronting the industry.

Lockout Cuts Ruhr Coal Output

A lockout May 6 of mine workers who rejected employers' proposals for a longer workday was quickly followed by a general strike in the Rhenish Westphalian mines, in the Ruhr Valley. The workers demand a seven-hour day, contending that their wages, which vary from 5.60 to 6.10 marks per day, are insufficient to maintain their strength for longer working hours. All the unions, both Conservative and Socialist, are in agreement in the demand, though only the Communists favor a strike. Coal reserves in the Ruhr are so limited that other industries will be affected soon and thousands of other workers thrown out of work.

The operators assert that they can meet the demands of the industrial agreement with the French only if production is cheap.

Champion Coal Loader Has Charley Horse

William Allen Bumpers, claimant of the coal-loading championship of West Virginia and Kentucky, is temporarily out of the running, due to a muscular ailment that makes it necessary for him to use crutches, but he expects to be back in the running again in a few weeks. During the last several months he said that he had been "going on high," turning out 60 tons of coal a day. His pay checks for January totaled \$499.42 and in February, the shorter month, he made \$399.56.

During the war his pay averaged \$26 a day for 18 months, when he turned out 40 tons a day. With the lowering of wages, following the war, he had to speed up a trifle, hence his more recent record of 60 tons a day. He is a non-union miner.

"At Hazard they paid me around \$700 a month for a time," said Bumpers, "but I'm usually found in West Virginia, where I have worked, on and off, for 26 years. Business is slow now and we aren't loading so much coal, but we are a lot better off than some of the closed-shop fields, where the union has the bigger wage scale, but less work."

Bumpers is a negro, weighs 177 lb. and is 45 years old, but looks much younger, although he is the father of six children and has worked hard all his life.

Government Fuel Yard Seeks Coal Bids

The Government Fuel Yard, Washington, D. C., will receive proposals up to 10 a.m., Wednesday, May 28, for the coal requirements of the district and federal governments for the fiscal year July 1, 1924, to June 30, 1925. The estimated requirements are 14,990 tons, more or less, of anthracite and 239,600 tons, more or less, of bituminous coal. Specifications may be had by addressing the Chief Engineer, Government Fuel Yard, Room 1139, Interior Department, Washington, D. C.

Coal Consumption and Power Output by Utilities Drops

Electric public-utility plants of the United States consumed 3,250,947 net tons of coal during March, according to a report just issued by the U. S. Geological Survey. This compares with 3,330,107 tons consumed in February and 3,664,258 tons in January. Fuel oil consumed by utility plants in March totaled 1,538,178 barrels, compared with 1,544,927 barrels in February and 1,618,591 barrels in January.

The average daily production of electricity by public-utility power plants in March was 160,700,000 kw.-hr., about 3½ per cent less than the average for the month of February. This decline probably was due in part to seasonal effect.

Practical Pointers For Electrical And Mechanical Men

How to Select Grinding and Polishing Wheels and Use Them Without Risk

What Kinds of Wheels Should Be Used and for What Purposes—How to Mount Them so that They Will Not Break—How to Order Wheels of Suitable Size

By GUSTAV RADEBAUGH
University of Illinois,
Urbana, Ill.

A MINE repair shop is not complete unless it has a good grinding stand and the necessary equipment to do all the grinding and polishing of the soft and tempered steel tools which must be used in general repair work. When a good serviceable grinding stand has been purchased for the mine shop and properly installed, the purchaser only too often is disappointed in the work it does. The reason for the workman's inability to obtain good work is directly traceable to material of which the grinding wheels are made.

To get good results from the machine only the best types and grades of wheels should be used. It must be appreciated that the grinding wheel is the business end of the machine. Often-times cheap wheels are supplied with the stand, and the operator has discouraging difficulties. The supplies used in the mine repair shop should be as good as those found in the best commercial shops.

To be able to meet all grinding demands, two types of grinding wheels should be supplied—one for tempered steel and the other for soft metals. The emery wheel so long used for grinding has been superseded by commercial abrasives known to the trade as carborundum, aloxite, alundum, and corundum. Manufacturers have published extremely useful information about

these abrasives. If you know what they are and for what type of grinding they are best suited you will be better able to select the right wheels for the grinding stand. Carborundum is a manufactured abrasive. It is not found in nature. It is a chemical combination of carbon and silicon. Carborundum is the trade name of carbide of silicon, a substance discovered by Edward G. Acheson in 1891. It is much harder than any other known abrasive. This gives it great durability. It is made up of small, sharp crystals just brittle enough to break slightly in use.

The sharp edges of the crystals cut clean and fast, and the brittleness of the material causes it constantly to present to the work fresh cutting edges, thus preventing the glazing of the wheels. The characteristic property of brittleness makes it highly efficient for grinding and polishing such metals as cast iron, chilled iron, brass, and bronze, also marble, granite, pearl, and in general, all materials of low tensile strength.

The abrasive material for grinding steel successfully must be not only hard and sharp but tough. These characteristics are found in aloxite, a new aluminous abrasive. Aloxite is the purest form of aluminum oxide. It is the product of the electric furnace, differing materially from other aluminous abrasives in several of its characteristics, the principal one of which is its temper, which makes it the ideal steel-cutting material.

In its crude form aloxite is taken from the electric furnace in an immense compact pig weighing several tons. This pig, by means of special, powerful machinery, is crushed or reduced to grain form. The aloxite grain then undergoes a thorough refining until every possible atom of impure matter is removed.

There are three processes of manufacture. The vitrified process consists of bonding the grain with certain clays, and vitrifying or baking at a high temperature. This changes the clays to a substance similar to porcelain. The vitrified wheels are most generally used

Fig. 2—Fitting the Wheel on the Spindle

An improperly fitted wheel is always dangerous. Broken guards and accidents frequently result from tight or loose wheels. It is usually disastrous to force a wheel on a spindle that is too large for it.

because, by this process, a wider range of grades can be obtained, because the wheels can thus be made more open and porous, thereby assuring a cool cutting wheel and because they are durable and stand up to the work. However, owing to its rigidity, vitrified material is not used where a thin wheel subject to side strains is required.

In the silicate process silicate of soda is used as the bonding agent. Wheels made by this process cut less harshly than the vitrified wheels and are used extensively for knife grinding and for sharpening saws and woodworking tools in mine shops, furniture, sash, door and blind factories and planing mills. Silicate wheels can be supplied with a wire web if desired.

Thin wheels usually are made by the elastic process, which consists of bonding the grain with a more or less elastic material, such as shellac or rubber. These wheels are extremely tough, fast cutting, and can be run without danger of breaking at high speeds and under moderately heavy side strains.

Most jobbers dealing in grinding wheels know the type of work for which the different wheels are used and have co-operation from the manufacturer in obtaining the best wheel for the job. It is more satisfactory in most cases, therefore, to leave the selection of the wheel to the dealer. The conditions under which grinding wheels are used vary to such an extent that no absolute rule can be given for selecting the right grain and grade. There are no wheels so constructed that all materials can be ground equally well with a single wheel. In mine repair-shop practice, however, it is not necessary to have more than two kinds of wheels.

One of the large manufacturers of wheels recommends for all the types of

Fig. 1—Testing a New Wheel

As soon as a new wheel is received at the shop it should be tested for flaws. This can be easily done by sounding it with a light steel hammer.

Fig. 3—Put Washers on Both Sides
A compressible washer made of leather, cardboard or heavy paper distributes the pressure of the flanges. Unless some such arrangement is used the wheel easily may be broken.

grinding jobs that will be done in the repair shop two wheels: One 14 in. in diameter, 2 in. thick, 1½ in. arbor, grit 24, grade H vitrified bond, of carborundum material; the other an aloxite wheel of the same dimensions, made of the same size of grit and bound with the same bond. The aloxite wheel is used for grinding all kinds of steel and the carborundum for castings, etc.

When a new wheel is received it is good practice to test it. (See Fig. 1.) Wheels in transit sometimes are broken or cracked, yet so slightly that the defect is not noticeable to the eye. A simple test is to strike the wheel a light tap with a hammer. If the stone rings it is safe for use. Before shipment all makers of good wheels test them at a speed approximately 50 per cent greater than that at which they are to be operated. On each wheel a tag will be found glued to the center. The kind of wheel (carborundum, aloxite, aluminum or corundum), the grain and grade, size, number, outside diameter, bore, surface, speed at which the wheel should be run, and the speed at which the wheel was tested are among the data found on this tag. This record should be filed away for reference. Having this information, if a wheel is not satisfactory, inquiry regarding it can be made. This tag is equally valuable as a reference when ordering a duplicate.

Do not force the wheel on the spindle of the machine. The diameter of the hole in the wheel should be at least 0.005 in. larger than the diameter of the spindle. It is essential that the wheel should not be cramped on its arbor. If it goes on the spindle free (Fig. 2) you may be assured that it will fit properly against the inside of the flange. Too much cannot be said about the importance of the wheel being mounted properly.

Flanges at least one-half the diameter of the wheel should be used. Compressible washers of leather, rubber packing or blotting paper, slightly larger than the flanges should be placed between the wheel and the flange (Fig. 3). If no washers are supplied with the wheel it is an easy matter to make up several of the heavy paper taken from cardboard packing boxes. A washer protects the wheel because it takes up any imperfection in either wheel or flange and thus the pressure on the wheel is distributed evenly when the flanges are tightened.

Table I—Diameter and Thickness of Wheel for Any Given Diameter of Spindle

Minimum Sizes of Machine Spindles in Inches for Various Diameters and Thicknesses of Grinding Wheels							
Thickness of Wheels in Inches	½	¾	1	1¼	1½	2	2½
Diameter of Wheel, In.	Diameter of Spindle in Inches						
4	½	¾	1	1¼	1½	2	2½
6	¾	1	1¼	1½	2	2½	
8	1	1¼	1½	2	2½		
10	1¼	1½	2	2½			
12	1½	2	2½				
14	2	2½					
16	2½						

When the wheel is placed on the spindle the nuts are too often turned too tight. The flanges should be tightened only enough to hold the wheel firmly, without unnecessary strain (Fig. 4). With the left hand the operator holds the bolt securely and with the right hand brings the nut up snugly against the washer. One jobber, to emphasize the danger of unnecessary tightening of the spindle nuts, makes the following statement: "On a 1½-in. floor grinding machine equipped with 8-in. standard relieved flanges a man with a 2-ft. wrench can easily exert

Fig. 4—Tighten the Nut Enough to Hold Wheel Safely

Excessive pressure should not be applied to the side of a grinder. Strains set up by clamping the flanges too tightly often result in breakage. An accident often happens from the cracking of a wheel before the defect has become apparent.

a crushing pressure of 3 600 lb. It is obvious that the wheel will be damaged if any such pressure is placed on it." The spindle of the grinding stand regulates the size of the wheels that can be used safely. Table I gives the diameter and the width of the wheels than can be used on a spindle of any given size. When ordering wheels this table should be used.

To Get Maximum Life Use Lamp of Right Voltage

The economy of burning lamps at their proper rated voltage cannot be too strongly emphasized because of the reduced life and efficiency contingent upon even a slight difference between the voltage at the socket and the rated voltage of the lamp. Lamps used on over-voltage circuits are brighter, but give their excessive light at a sacrifice in life. When lamps are operated at under-voltage, the life is, of course, increased, but the efficiency is greatly decreased.

The life of the average Mazda lamp is one thousand hours, when operated at rated voltage. Fig. 1 shows how the life of the lamp decreases when it is operated at a voltage higher than that for which it was designed. For example, consider the effect of using a 110-volt lamp where the actual voltage at the socket is 115. This seems like a small difference, doesn't it? Yet the curve shown on Fig. 1, which has been determined from a large number of tests, shows that the actual life of the lamp will be only 140 hours, or 14 per cent of its rated life. In this case, an increase of 4.5 per cent over the rated

Fig. 1—Relation of Lamp Life to Voltage of the Circuit
Even a very slight increase of line voltage greatly reduces the life of an incandescent lamp. A 5 per cent over-voltage cuts the life of the lamp in half.

Fig. 2—Candle-Power Greatly Reduced on Low-Voltage Circuits

By operating a lamp on a circuit having a voltage lower than the rating of the lamp the life is increased but the efficiency and candle-power are reduced.

voltage causes a decrease of 86 per cent in lamp life. If a lamp rated at 110 volts is placed on a 220-volt circuit, it will burn out instantly.

Fig. 2 shows the effect of operating lamps at a voltage lower than the rated value. If, for instance, a 110-volt lamp is used on a 100 volt-circuit, the light output would be only 74 per cent of its rated value. In this case, the candle-power is decreased 26 per cent by a 10-per cent under-voltage.

The obvious remedy, of course, is to use lamps having a voltage rating equal to the average voltage at the sockets. The voltages of lighting circuits have been standardized into two ranges, namely, 110, 115 and 120 volts, and 220, 230, 240 and 250 volts, the first range, particularly the 115 volts, being that generally used. Special lamps of voltage ratings other than those listed above are obtainable, but they should not be used because it is difficult to obtain them and because they are more expensive.

FRANK PAESKE.

Production And the Market

Bituminous-Coal Markets Show Little Change; Sentiment More Cheerful

The long looked-for and much hoped-for improvement in the bituminous coal market has not yet materialized. The general situation is as unsatisfactory as at any time during the last few months; demand is weak and fitful, production holds at rock bottom, a large number of mines are still idle and the running time at those working is sadly curtailed. As a consequence prices have a hard time holding their own at even the discouraging levels of recent weeks. None the less there are indications of an improvement in sentiment, based to some extent upon the gradual disappearance of distress coal. The signing of contracts is far from brisk, but movement to the lakes is picking up, shipments by the Hocking Valley R.R. to Toledo being three times as large as at this time a year ago.

Hoover Urges Early Buying

In order to spread out the movement of coal and thus ward off possible car shortage and traffic congestion next autumn Herbert Hoover, Secretary of Commerce, has addressed a letter to secretaries of national and state trade associations urging manufacturers to purchase and store coal during May, June and July, when bituminous-coal prices are low and the railroads in better condition to handle the traffic.

That one-time radical, Frank Farrington, miners' union president in Illinois, recognizing the economic crisis that confronts the union in that state proposes a giant power plan to increase coal consumption, pointing out at the same time the necessity of co-operation by the miners with the operators to cut down production costs in order to lessen the inroads of competition by non-union fields.

Coal Age Index of spot prices of bituminous coal on May 12 was unchanged from the preceding week, standing at 169, the corresponding price being \$2.05.

Dumpings at Hampton Roads for all accounts during the week ended May 8 totaled 293,849 net tons, as compared with dumpings of 326,962 net tons during the preceding week. Cargo coal dumped at Lake Erie ports during the week ended May 10, according to the Ore & Coal Exchange, amounted to 450,570 net tons, and of fuel coal 32,726 tons. This compares with

500,740 tons of cargo coal and 20,708 tons of fuel coal dumped during the previous week.

Production of bituminous coal revived to the extent of 108,000 during the week ended May 3, when, according to the Geological Survey, the output was 6,832,000 net tons. This compares with 6,726,000 tons produced during the preceding week. Anthracite output also took an upward turn, 1,616,000 net tons having been produced, compared with 1,205,000 tons during the week ended April 26.

Curtailed production of anthracite due to local labor disturbances has stiffened the hard-coal market. Independent domestic sizes are now quoted at close to company circular and in some instances shippers have had to refuse orders for immediate delivery. The strong demand for pea coal has led many to believe

that the country was short of domestic sizes, but the movement is explained largely by the fact that a number of consumers take some of this size in order to get more of the larger sizes. Stove continues to be in strongest demand, egg being next and chestnut third.

Midwest Feels No Pick-Up

Nothing happened during the past week to strengthen the coal market in the Midwest. Storage stocks are by no means exhausted yet, either in the hands of railroads or industrials, so that demand for all grades continues light. Enough coal is coming out of western Kentucky to reduce the effect that might have been created had the strike in that region stopped all work. The resumption of work in Kansas, Oklahoma, Arkansas and Missouri, with a slight freight-rate advantage from those mines to some of the Missouri Valley markets, has started a flow of fresh coal from that territory. All in all, the Midwest remains unencouraged by any element that might put strength into the trading. A little contracting is going on all the time, but the volume of it is small.

Production in Indiana and Illinois continues at rock bottom. Neither state shows any improvement from the

average 20 to 30 per cent of recent weeks. In the southern Illinois field little is moving except steam sizes, for which there is some demand. The Mt. Olive field is practically at a standstill. The Standard field is moving out some 2-in. lump, but there is no domestic market. Mines supplying railroad coal are about the only ones working. A good many unmarried miners have left these fields for parts unknown. Unrest is noticeable among those with families who cannot move so easily.

Business is practically stopped at St. Louis. There is no domestic tonnage moving and wagonload steam is just barely in evidence. The public seems a little inclined to put off buying this year, although prices are down to rock bottom. Country business is at a standstill, excepting a little trade in chestnut anthracite. Country steam shows a little activity here and there and the demand for screenings in outside markets continues good.

Kentucky Trade Is Slow

The Kentucky market is very dull, although the Big Four, Southern and Louisville & Nashville railroads have been taking a fair amount of coal. It is reported that the Wisconsin Steel Co., operating at Benham, Ky., has been moving some industrial fuel to its mills and also to the

Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines

	1924	1923
Index	May 12	May 5
Weighted average price	169	169
	\$2.05	\$2.05
	171	226
	\$2.07	\$2.73

This diagram shows the relative, not the actual prices, on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913-1918," published by the Geological Survey and the War Industries Board.

Lakes for movement north, but there doesn't appear to be much contract business developing on lake shipments, and the big utilities and industrials are buying lightly. Retail business has slumped off. Eastern Kentucky operators, as a result of favorable wage scales, are enabled to obtain some business on a price basis that otherwise would be denied them on account of freight hauls. Although more than half of the western Kentucky field is down on account of the District No. 23 strike, the remaining mines are not busy. However, orders for prepared are light, which is resulting in screenings being scarce and comparatively high. Prices of prepared coal are holding rather firmly.

Little Doing In Northwest

Business is extremely slow throughout the Northwest except in a little hard coal to meet immediate demand during a slight cold spell. Price reductions on many soft coals at the Head-of-the-Lakes did not stimulate trading much. Variations in anthracite prices are noticeable. While at Duluth a 10c. advance was made May 1 and further advances were promised for the rest of the summer, at Milwaukee slight decreases were put into effect to stimulate early buying. Shipments from the Duluth docks last month were good. In all 15,683 cars went out as against 13,619 in the preceding month and 7,555 in April of last year. Nearly all of this coal went to the railroad companies' yards as little selling was done. The larger number of cars (9,043) went from the Duluth side of the harbor, which is unusual. This was done to save tax assessment for coal on docks as of May 1.

To date 41 cargoes of new coal have been unloaded at the Duluth-Superior docks for a total of 318,090 tons. Ten of the cargoes, aggregating 79,230 tons, were anthracite. Eight more cargoes are ready to enter the harbor, but the ice cap has closed down and many boats are held out in the lake. All coal of the defunct Superior Coal & Dock Co. has been sold. This removes much cheap coal from the market. At Milwaukee the May reduction in soft coal has had the effect of stimulating business to some extent. Milwaukee receipts of coal by lake thus far this season aggregate 68,576 tons of anthracite and 113,599 tons of soft coal. Lake freight rates have been reduced 50c. per ton. The coal movement promises to be slow during the summer.

West Is Largely Inactive

Few mines of the Southwest have resumed work as a result of the recent wage agreement in Kansas City between operators and miners. Some "no bills" accumulated on Kansas tracks even during the month's suspension, the product of independent mines, the operators of which signed with the miners before the association did. Only a heavy storage demand could result in operation to any extent in the Southwest this summer. The market in Colorado shows very little change. Sales are at a standstill. Mines worked on an average of twenty hours last week and a number of them report "no bills." The operators' weekly reports show more than 30 per cent of the time lost attributed to "no market." The railroads also report a considerable decrease in the shipments of commodities from the coal producing districts. Utah operators are moving very little coal. Although working time is but two days a week, "no-bill" cars are increasing. Mining and cement companies are buying a little coal, but outside of these industries the demand is at a very low point. The domestic demand is for intermediate sizes. Nothing has been said regarding storage rates this year. It is unlikely that the operators will make a reduction.

Solid Undertone at Cincinnati

Business in Cincinnati had a more solid footing during the past week. Gradual elimination of the producers south of the river who threw coal on the market whether it was needed or not, the passing of a bulk of the tonnage that was coming on consignment and a minimum of "distress" fuel are the outstanding causes. Increase in Lake business and buying by large consumers whose stockpiles are at a level where they must replenish also have been helpful. The retail trade has settled down to an even tenor for the month apparently, for there has been no change in quotations. Low bids on county business is the only disturbing factor, but this is not taken to mean any great change in prices. An increased tonnage from the Kanawha River with more coming over the elevators at Huntington is the feature of the river trade. Specialized coals are quoted as follows: Block, \$3@3.50; egg, \$2.50@3. The Columbus market notes a better feeling in steam trade. A large part of the railroad contracting has been done and Hocking Valley operators got their share of the tonnage; quite a number of smaller agreements also have been placed. Steam requirements are not as heavy as formerly and some of the larger consumers are still using reserves. Some school coal also is moving and public utilities are coming into the market again. On the whole there is a better tone to the trade although there has been no especial strengthening in quotations. Producers have reduced output to a point where there is little distress coal on the market. Retail trade is quiet. Lake trade is slow. Cleveland operators and jobbers report an extremely quiet market and even consumers who have no stocks on hand are buying from week to week in small quantities rather than a thirty-day supply. Furthermore, there seems to be a slight slowing down in industrial activity, and consequently consumption is much below normal. However, the New York Central reports an upturn in the volume of loads moving through its Cleveland terminals, as compared with the daily average a week or so ago. The increase has been gradual and consistently upward during the past ten days. With a slightly increased production of lump coal for Lake, the quantity of slack in the market has become more abundant, and spot prices on slack and nut and

slack have receded about 10c. per ton. There is practically no change in spot prices on other grades.

Line demand at Pittsburgh continues extremely poor. The market is spotty from day to day, but a week's average shows no material change in volume. Railroad demand is still the chief support of the market. Prices are unchanged.

Practically all the non-union mines in Somerst, Cambria and Westmoreland counties, in the central Pennsylvania district, have gone back to the 1917 scale and operators are thus able to compete with southern conditions and, as a result, mines are operating on practically full time, with the exception of the Berwind-White Coal Co., at Windber, which is still paying the higher rates and is working two to three days per week. A further evidence of the effect of the new scale is shown in the loadings for the week ending May 3, which totaled 10,439 cars, as against 9,954 for the previous week.

The trade at Buffalo continues quiet. Slack is in better supply and the prospect of an advance in price seems to have disappeared.

Price Recession Feared in New England

In New England there is no material change either in prices or in the attitude of buyers. The industrial situation is in no wise improved, and the more pessimistic in the trade are apprehensive lest quotations again recede. In fact, prices for spot loading f.o.b. vessel at Hampton Roads are 10c. less than a week ago. While numbers of operations are working but one to two days weekly there are still moderate accumulations at the Virginia terminals, and the agencies find themselves pressed to relieve cars. In no direction is there hope of a much better market during May.

Prices per gross ton on cars Boston also have eased somewhat within a few days; \$5.35 is quoted, as compared with \$5.50 a week ago, although a few factors are trying to get as high as \$5.75. The market is governed, however, by those larger distributors who are obliged to make room for weekly arrivals.

All-rail from central Pennsylvania there is only scattering demand at minimum prices. Except within a narrow zone east and west of the Connecticut River and well away from tidewater there is no market whatever for grades other than a few specialties.

Better Tone in Seaboard Markets

Consumers at New York are making some interesting inquiries which are expected to develop into real business. As a whole, the market is in better shape. This is not apparent, however, by comparing the price list with previous weeks, but in the general attitude of the trade. There appears to be more optimism abroad and those coal men who a few weeks talked dull trade until August are advancing their revival date a few weeks at least. Less coal is coming to the New York tidewater and more strength is apparent, causing less tendency to cut prices in order to sell coal. The daily average of cars on tracks at the piers last week was less than during the previous six days.

Philadelphia finds coal still difficult to move, and more mines than ever are reported as being closed down or working short time. Big consumers are sticking to stockpiles for coal, and the fact that apparently more coal is being consumed than is being mined is really the one favorable aspect to the market. The recent slight flurry in tide movement seems to have quieted down about as quickly as it arose, as the past week has seen no clearances of

coal at all. Bunkering remains on the same plane as maintained during the past ten weeks or more.

Although production has been greatly curtailed in some sections of West Virginia apparently it is still in excess of current demand and possibly of consumption. Within the last few weeks, if anything, there has been a slight increase in the tonnage mined and loaded as observed in increased shipments to the Atlantic piers. The fact that there are so many mines in idleness in northern West Virginia has created a small increase in business for such mines as are running and has resulted in a scarcity of screenings, but so far there has been no advance in prices worth mentioning, either as to high or low volatile.

There was an almost complete cessation of activities last week in the Baltimore market. Few dealers are now chancing heavy shipments to tide for the spot market, as there has been difficulty in getting rid of this coal without heavy demurrage charges. The export movement, which for some time has been the one encouraging feature, has taken a drop for the first week of the present month.

Demand at Birmingham is extremely light, consumers showing little interest in solicitations and buying only for immediate needs. The Frisco Railroad has closed its contract for fuel for the next twelve months, this contract having been pending for several weeks. Business in export and bunker channels is negligible at present, a limited tonnage moving to Cuban and South American points.

Brisk Tone in Anthracite Trade

Weather conditions have helped consumption to such an extent that many New York retail dealers have not been able to fill their orders as rapidly as they would have liked. All domestic sizes are in strong demand. Stove coal leads the list and straight lots of that size bring the maximum quotation, but when taken with chestnut or egg may be had for 15c. to 25c. less. Chestnut is the hardest of the three coals to move. Pea is in good demand also. The steam coals are easily moved, with rice and barley the strongest.

An improved tone marks the trade at Philadelphia this week. Cool weather has helped in a measure to keep up a fair demand for current consumption. Dealers report consumer ordering slow and not much stimulated by increased mine prices. The retail price situation remains unchanged. Steam sizes have in no wise improved.

Baltimore retailers report a fair amount of orders, but that supplies on hand are adequate to meet the situation. The public apparently is taking advantage of the fact that prices probably will not be raised by retailers until July 1, and are endeavoring to get coal in cellars in many cases.

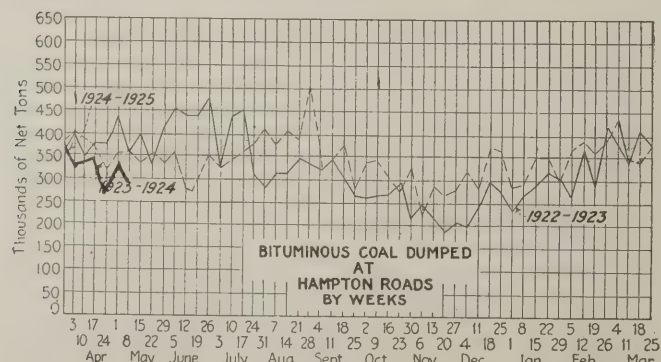

Coke Output Continues Steady Decline

Spot furnace coke remains quotable at \$3.60@3.75. Foundry coke is in poor demand and really standard foundry coke remains quotable at \$4.75 to \$5.25. Output of beehive coke during the week ended May 3 was 205,000 net tons, according to the Geological Survey, compared with a production of 224,000 tons during the previous week.

Foreign Market

And Export News

British Coal Market Disorganized;

Production Slumps Further

The Welsh steam-coal market is suffering from disorganization and instability. The Easter holidays have in most cases been unofficially prolonged by the miners on account of the brilliant weather, and in consequence output has fallen and foreign buyers have made heavy purchases of American and German coal. These are some of the factors that account for the instability in South Wales. In addition merchants holding contract supplies are offering them at lower rates than the collieries. In these circumstances values have a marked tendency toward weakness.

Pit stoppages are numerous owing to the accumulations of stocks and the stormy weather interfering with exports. The recent decline in prices has attracted more business and buyers are refusing further concessions. The strike of trimmers at Leith threatens to spread to other ports.

The Newcastle market is suffering from a spring lassitude, and, all round, much the same conditions prevail as in South Wales.

Production by British collieries during the week ended April 26, a cable to *Coal Age* states, was 4,049,000 tons, according to the official reports. This compares with 4,994,000 tons in the week ended April 19 and 5,843,000 tons during the week ended April 12.

French Coal Market Steady

In All Lines

The French coal market is firm and steady in all lines, but disposals are extremely rare in the North and Pas-de-Calais, despite a continual increase in production. Imports of British coal are still large, but prices are more accessible with the decline of Sterling.

Owing to the new taxes imposed on the collieries, some of them intend to raise the prices of industrial fuel 15 to 30 centimes per ton.

Demand for household coal has slackened in anticipation of summer rates.

The Belgians having definitely established summer rebates at 8 fr. per ton for May and June, 4 fr. in July and 2 fr. in August, the Paris coal traders have issued their summer schedule.

Supplies of coke to the O.R.C.A. during April averaged 19,500 tons daily, which is slightly under the usual record, due to the slackening of activity occasioned by the Easter holidays. The price of coke for April will be 150.75 fr., all charges included.

The prices of reparation coal have just been lowered 10 per cent in Belgium, and similar action is expected soon in France.

Trade Steady at Hampton Roads;

Prices and Tone Firm

Business at Hampton Roads is holding its own, with no apparent increase in activity in the market. Prices hold firm, with scarcity of Pool No. 2 as perhaps one of the striking features of the market.

Coastwise and bunker trade is fair, but foreign movement shows an inclination to drop off. Old orders are being completed and no new contracts for overseas shipments are to be noted in the market.

The tone of the market is firm, and the outlook shows little prospect of any immediate increase in trade.

News Items From Field and Trade

ALABAMA

The Big Sand Iron & Steel Co., Birmingham, has changed its name to Big Sandy Coal & Iron Co., and is said to be planning improvements to its properties in Tuscaloosa County, near Coaling.

Advices from Cullman, in Cullman County, state that much undeveloped mineral lands are being bought up in that section by L. B. Musgrove, of Jasper, organizer of the Deepwater Coal Co., recently formed, and that Henry Patillo, of Cullman, also is buying up lands in Cullman and adjoining counties, which it is believed carry valuable coal deposits.

The Crow Coal Co., which was recently incorporated, has been organized with Charles B. Crow, president and W. W. Bankhead, secretary and treasurer. It has 80 acres under development, with a daily output of about 250 tons, at Jasper.

The Stith Coal Co., Brown Marx Building, Birmingham, of which A. B. Aldridge is secretary, has bought the Drifton mines in Walker County, including about 15,000 acres of land, drift mines, about forty houses, store and other appurtenances.

The Bankhead Coal Co., Bankhead, of which W. D. Leake is general manager, has let the contract for a steel tipple of 3,000 tons per day capacity.

COLORADO

Substantial progress has been made in driving the Moffatt tunnel. Already Hitchcock & Tinkler, Inc., the contractors, have completed 2,200 ft. of the water tunnel at the east end of the bore and 2,500 ft. on the west end. The main railroad tunnel has been completed 320 ft. in from the east, and the narrow heading which precedes it is now 1,700 ft. long. Although the contract calls for completion of this railroad bore under James peak by July, 1927, the contractors now announce that they will have the job done in 1926. The tunnel is expected to give considerable impetus to the development of the great Routt County coal region, now handicapped by doubtful transportation.

An effort to reduce miners' wages in Colorado caused a strike of the 100 men at the Broadhead mine of the Temple Fuel Co. at Aguilar early in May. The company had announced a reduction of 15 per cent in wages with a statement from President F. R. Wood saying that, because of the 50 per cent

drop in the price of coal, the mine had been running at a loss for the preceding 60 days. The union men, presided over by Mike Livoda, vice-president for the Colorado district, voted to suspend operations until the old wage scale is restored. The strike is legal, according to the State Industrial Commission, to whom miners appealed several days ago. The company has made no attempt to operate the mine during the dispute. Mr. Wood also is president of the Colorado & New Mexico Coal Operators' Association.

Colorado coal mines yielded 10,336,735 tons in 1923, an increase of 333,125 tons over the output for 1922, according to the annual report of James Dalrymple, State Coal Mine Inspector. During 1923 the average number of men employed in the mines was 13,277, with an average of 169.9 days worked per mine.

The National Fuel Co. is being sued by Albert S. Nelson, a farmer in Colorado, for \$103,000 on the ground that its coal operations have so disturbed the surface of land under which they leased coal rights, that farming is impossible. Nelson charges that some of the holes sunk "in all sections" of his ranch are "40 and 45 ft. in diameter."

ILLINOIS

Work has been resumed by the Rex Coal Co. at its mine at Warner, near Coal Valley. A new airshaft has been sunk and two shifts of men are now being employed.

A total of 150 miners employed by the Madison County Coal Co. have petitioned for a receiver for that company to be appointed by the Circuit Court of Madison County at Edwardsville, Ill. The miners in the petition state that the company was unable to meet a \$13,000 payroll. Thomas R. Harris of St. Louis is president of the company. Slow collections are said to have caused the company embarrassment.

John Foster, who for several months had been superintendent of Mine No. 1 of the Chicago, Wilmington & Franklin Coal Co., at Benton, has been transferred to Herrin, where he has been appointed superintendent of Mine A of that company.

H. M. Prigge & Co. has been incorporated at St. Louis with a capital of \$20,000 and will mine and manufacture coal, coke, fuel, pig iron, fireclay, sand, and silicates. The incorporators are Henry M. Prigge, Martha J. Prigge and William Meinholtz.

Marshall M. Ennis was elected trustee of the Drakesboro Coal Co., Inc., at Drakesboro, Muhlenberg County, by the creditors at a meeting held on May 1, before John L. Stout, referee in bankruptcy. Ennis has been serving as receiver since the company went bankrupt. The stock consists of a coal mine and store.

H. J. Elliott, for 24 years well known throughout the Middle West as a representative of the Pittsburgh Coal Co. and for seven years the Chicago manager of that company, has resigned and is now spending the summer in his home country in and near Minneapolis, Minn., fishing and resting. His business plans for the future have not yet matured. J. D. Sauerberg, who has been with Mr. Elliott every year of the 24 in the Chicago office, is the present manager.

INDIANA

Representatives of the U. S. Bureau of Mines and of the Indiana mine inspection bureau recently conferred with John Hessler, president of District No. 11, United Mine Workers, to consider preliminary details of the State first-aid meeting to be held June 28 at Princeton.

The Dering Coal Co. has announced that Dering mine No. 6, at Clinton, which has been closed for some time, will be reopened immediately. This is one of the largest mines in the Clinton field.

Two new Indiana mining companies have been organized. The St. Clair Coal Co. has been incorporated at Bicknell by Charles Goodman, Thomas Thomas, Henry Brown, Patrick Penman, Alexander Campbell, Charles Holt, Lewis Steffy, John Thomas and Howard Taylor, all of Indianapolis. The Emcke Coal Co. has been incorporated at Terre Haute with a capital stock of \$100,000 to mine coal in that section of the state. The incorporators are W. L. Mace, John H., and A. J. Beasley, all of Terre Haute.

The Brooks-Hoffman Coal Co. has been incorporated at Vincennes, for the purpose of doing a general mining business. The incorporators are Lewis Brooks, Nolan McClure, William E. Ruble and Thomas J. Brooks, all of Vincennes, and Harry H. Hoffman of Petersburg, Ind.

The Patoka Coal Co., which operates a stripping mine at Rogers, six miles east of Petersburg, closed recently, awaiting a revival in the coal markets—if any. The company has been operating all winter and this is the first

suspension in a year. Other mines in Pike county are operating only from one to three days a week.

W. H. Leland, Chicago, president of the Leland Coal Co., closed a deal May 6 at Evansville with Jabez Wooley, president of the Warwick Coal Co., for the Polk Patch stripping operations, near Boonville, in southern Indiana, at a reported price of \$500,000. The Leland company now owns nine operations in Indiana, Illinois and Kentucky.

KANSAS

The Central Coal & Coke Co., of Kansas City and Pittsburgh, has purchased nearly 30,000 acres of land south of Coffeyville, all but 2,000 acres of which is in Oklahoma. The Santa Fe R. R. is to build a spur to the new field, development of which is under way.

KENTUCKY

The Dempster Coal Mining Co. of St. Charles, of which Geo. R. Dempster is president, is reported to have acquired the plant of the bankrupt Harris Collieries Co., at Island, and is planning the removal of the equipment to Earlington.

It is reported from Pinesville that several union miners and their families are moving from the property of the Liberty Coal & Coke Co., on Straight Creek, following expiration of the thirty days' eviction notices posted by the company in early April. On April 30 Judge Cochran, of the federal court, Eastern Kentucky division, in a hearing at Richmond, indicated that federal authorities would eject the miners if they did not move, and the court granted a preliminary injunction against United Mine Workers of District 19, the Straight Creek local union, and forty-two miners, who it was related were living in company houses.

Official denial has been made by the Ford mining interests that the Pond Creek mines of the company have been shut down as a protest against the presence of union organizers in the field. The company has been paying its men a little above the union scale but has operated open shop and has been having some difficulty with the union as a result.

Two men were killed and a third was excavated alive following a cave-in of a small area in a low level of the Black Diamond mine of the Pacific Coast Coal Co., April 28.

NEW YORK

John T. Roberts, for several years general sales agent of the Widnoon Coal Mining Co., has organized the Widnoon Coal Co., to be operated in the general bituminous trade, as the mine has been closed for some time, waiting for better business. The new company will be incorporated later on, business proceeding outwardly as before.

George A. Hughes, secretary of the Lake Erie Coal Co., has sold his interest in it and organized the Lake Erie Fuel Corporation, with office at 812 Prudential Building, Buffalo. The

incorporators are himself, S. A. Crone and H. B. W. Haff, of New York. W. L. Rowland, of the older company, son of the president, has been appointed Northern sales agent of that company, which is an auxiliary of the Richland Coal Co., of Wheeling, W. Va.

It is announced that the Buffalo office of the J. P. Burton Coal Co., of Cleveland, will be closed on June 1, owing to poor business and it is understood that other branches will be discontinued for the same reason. A. R. Stubbs has been head of the Buffalo office.

©Harris & Ewing

Walter D. Rogers

Resigned May 1 as executive secretary of the National Retail Coal Merchants Association, which position he had held for six months. He was with the U. S. Coal Commission, for which he made an investigation in Boston and also made special cost studies in New York and Washington, D. C. He also was one of the authors of the commission's report covering the retail trade.

OHIO

Operators in the southern Ohio field are trying to get miners in that district to hold another referendum on a joint conference to change working conditions in the district. Several weeks ago it was voted down by the miners' organization with but one-third of the members voting. Operators believe that if another vote is taken it might be carried. It is planned to lessen the cost of dead work in order to reduce the cost of production in the district and thus enable the operators to compete with the West Virginia fields.

Coal Production in Ohio totaled 40,726,615 tons in 1923, according to a report to Herman Witter, Director of Industrial Relations. This compares with 27,526,555 tons mined in 1922, a gain of nearly 50 per cent. The 1923 output has been exceeded only three times since statistics have been kept, the peak year being 1920, when 45,227,077 tons was produced.

The Yorkville Mining Co., Yorkville, is having a switch laid from the Wheeling & Lake Erie R.R. to receive shipments from its mine. The Yorkville company has supplied large industrial consumers by truck and boat since its mine was opened a few years ago.

Considerable surprise was shown by the Cincinnati trade when the figures were announced for the county bids opened May 6. On West Virginia mine run the low was \$3.79, and for smokeless \$5.70. This is inclusive of freight and haulage and with a penalty clause attached.

Upon application of the West Virginia Rail Co., of Huntington, with a claim of \$24,039, ancillary receivers in Ohio for Jewett, Bigelow & Brooks were appointed in the U. S. Court at Cincinnati by Judge Smith Hickenlooper. E. L. Douglass, vice-president of the company in charge of operations, and John L. Richey of the Cincinnati Credit Men's Association, qualified under bonds of \$25,000. They had been appointed receivers for the company by Judge A. M. J. Cochran in a hearing before the U. S. District Court of eastern Kentucky. The only objection to the ancillary receivership was put in by Louis H. Stone and his wife, who claimed to be indorsers of notes up to \$700,000. The receivers sought to have stockholders enjoined from interfering with them. E. H. Jewett, president H. M. Jewett (also president of the Paige Motor Co.) and Walter Brooks, treasurer, were in Cincinnati recently but refused to say what conclusions they had arrived at as to the future conduct of the company.

Frank L. Stein and William S. Harman, receivers of the Maynard Coal Co., called a meeting of creditors May 10 to discuss the advisability of accepting an offer of \$650,000 and accrued unpaid taxes amounting to \$8,500 for the properties of the Superior Coal & Dock Co. at Duluth. Creditors were not inclined to accept, but wanted more time for consideration. The receivers will put the question up to Judge J. E. Sater, of the federal court, for final action.

PENNSYLVANIA

James A. Gleason, member of the executive board in District No. 1, United Mine Workers, will be grand marshal of the miners' parade to be held in Scranton at 1 o'clock on the afternoon of May 30, in connection with the unveiling of the John Mitchell monument on the Court House Square. Miss Kathryn Mitchell, daughter of the late union chief, will unveil the statue.

A settlement of the strike which tied up the 8,000 mine workers of the Panther Creek Valley collieries of the Lehigh Coal & Navigation Co. since April 14 was effected last week by Thomas Kennedy, president of District No. 7, United Mine Workers, and James A. Gorman, secretary of the Conciliation Board.

The Philadelphia & Reading Coal & Iron Co. has instituted a reforestation campaign. A large force of men is engaged in planting 25,000 Japanese red pine and 25,000 Scotch pine trees in the vicinity of Mount Carmel and Kulpmont. About 25,000 Japanese red pine also are being planted in the outskirts of Shamokin. The work is in charge of William Smith, district forester of the company.

The Sloan breaker, one of the oldest of the Glen Alden Coal Co.'s coal-preparing plants, will be dismantled within a few weeks. Maurice Sullivan, mining contractor, well known in the upper anthracite field, will tear down the operation and with it the Hampton Tower and several other buildings in the western part of Scranton.

The Glen Alden Coal Co., of Scranton, has completed the purchase of 5.08 acres of coal land in the fifth ward of Scranton from Eleanor E. Hoxie. The consideration was not made known.

With the visit of W. H. Grady and W. E. Decker, representing the Kemmerer interests, of New York, controllers of the Mount Jessup Coal Co., reports were current in Scranton of the reorganization of the coal company and resumption of operations. About a month ago all collieries of the company in Jessup ceased operations, throwing 2,000 men out of work.

The Philadelphia & Reading Coal & Iron Co. has flushed 1,500,000 sq.yd. of old mine workings underneath Mount Carmel borough and is continuing the work.

Officials of District No. 1, United Mine Workers, are investigating reports to the effect that the miners' certificate law is being violated in the district. They believe a large number of immigrants have obtained certificates through false statements and if they find evidence to confirm their belief they will institute proceedings, they say.

The Philadelphia & Reading Coal & Iron Co. has erected a separate wash house with shower baths, booths and dressing rooms at Donaldson, midway between the old West End and Middle Creek operations, at a cost of between \$20,000 and \$25,000.

The Dodson Coal Co., operating at Beaver Brook and Locust Mountain, has moved steam shovels and other equipment at Locust Mountain to Raven Run, where a new stripping operation is to be started. The Dodson company has one of the biggest strippings in the world at Locust Mountain.

Appeals from the state anthracite tax, taken to the U. S. Supreme Court by coal companies, will not be heard until next autumn, as the court will be unable to reach them before the summer recess. Several million dollars of taxes are involved.

There is an increase in the number of evening mining classes conducted in Pennsylvania this year and the number of pupils is greatly increased over last year, according to the State Department of Public Instruction. "Mining courses in evening schools were organized this year in thirty-two school districts of the state," said Dr. J. George Becht, State Superintendent of Public Instruction, "and more than 1,500 men were enrolled in the different courses. The growth is remarkable in view of the fact that only six school districts in the state conducted courses in mining last year. This increase is due to the co-operative efforts of the State Department of Mines, State College and the Department of Public Instruction."

UTAH

The Utah Oil Refining Co. of Salt Lake City has definitely decided to use coal for fuel purposes and its plants will be changed accordingly. This will provide a new outlet for 600,000 tons of coal a year. It is stated that through a new refining process it is now possible to dispose of the oil that was used for fuel at a rate that would make it unprofitable to continue to use it for fuel.

F. F. Green

Recently promoted to the superintendency of the Valier Coal Co. mine at Valier, Ill. He formerly was chief engineer.

The U. S. Land Office at Salt Lake City offers for lease a tract of public coal land containing 1,818 acres in the Castlegate district of the Book Cliffs coal field about 3 miles northeast of Castlegate on the Denver & Rio Grande Western R.R. Lease for this tract will be at a government royalty of 10c. a ton for coal mined, a minimum investment in mining operations of \$50,000 during the first three years of the lease, a minimum production of 60,000 tons a year beginning with the fourth year of the lease. Leasing of this land is made in accordance with the general leasing law.

WEST VIRGINIA

The tippie at the plant of the Morgantown Gas Coal Co. at Murray, formerly known as Mine No. 93 of the Consolidation Coal Co., collapsed late in April, under the weight of several loaded cars and a string of empties. The accident happened when a Monongahela Ry. engine was backing empties into the siding, with loaded cars in front.

The Fairmont-Chicago Coal Co. has completed work on its new tippie at Barackville and the first coal was dumped over the structure late in April. Approximating 1,200 tons of coal a day are being loaded over the new tippie but it is proposed to gradually increase the amount to 2,000 tons a day. The new tippie is equipped with shaker

screen, picking table and loading boom equipment. W. E. Watson, of Fairmont, is president of the company.

The Island Creek Coal Co. has let contracts to the Hatfield Construction Co. for the construction of hard roads in Logan which will entail an expenditure of \$310,000. Roads to be paved include the Whitman's Creek, Trace Fork and Copperas transportation routes. All of the contracts, which call for the surfacing of about nine miles of roads with concrete, are expected to be completed by Sept. 1. The Island Creek company has already expended more than \$100,000 in grading the projects now to be paved.

The Rachael Gas Coal Co. has disposed of its Rachael mine and coal holdings at Downs, W. Va., near Fairmont, to the Bertha Consumers Coal Co., of Pittsburgh, Pa. The consideration, as shown by the deed filed, was \$536,000. The Rachael plant is one of the new ones in Marion County and is a large mine with modern equipment.

John C. Lowry, Jr., has been appointed general superintendent of the New River Collieries Co. Mr. Lowry is a graduate of Pennsylvania State College and had his start with the company.

Industrial Notes

A new coal company, launched at the outset of May was the Marmon Coal Co., with headquarters at Buckhannon, in the Upshur County field. This concern is capitalized at \$75,000. Chiefly interested in the new concern are A. M. Miner, Irvin Christner, George Christner, A. L. Quimet, Jr., and Amie Quinett, all of Buckhannon.

The McClanahan Pocahontas Coal Co. has just been organized to operate in smokeless territory, headquarters of the company to be at Cotter. The new corporation is capitalized at \$100,000. Among those identified with this company are K. S. McClanahan, of Amigo; William McClanahan and D. E. Claypool, of Cotter; W. A. Harrah and W. K. Harrah, of Backus.

The Wingo Manufacturing Co. has been incorporated at St. Louis, Mo. with a capital of \$300,000 and will manufacture and sell mine doors, automatic gates and switches. The incorporators are William W. Wingo, Joseph K. Cosinski, Helen Cosinski, Minnie Wingo and George W. Royce. Minnie Wingo and George W. Royce, Paul J. Pirmann, Fulton, Mo.

Craig Miller, president of the Man Coal Co., of Man, W. Va., accompanied by his chief engineer, Mr. Barrett, were in Cincinnati recently looking over plans and new equipment for developments at their mines.

The Lehigh Coal & Navigation Co. is about to commence the construction of a steel tippie in the Panther Creek Valley region, near Lansford, Pa. The cost, including machinery, will be about \$1,500,000.

Contracts have been let for building a washery for the Harleigh Coal Co., at Harleigh, near Hazleton, Pa. The plant has been designed by H. M. Chance & Co., and will be equipped with one Chance sand flotation separator 15 ft. in diameter. The steel structure will be bolted—not riveted—so that it can be moved when the culm banks to be worked are finished. Much of the material and machine equipment has already been fabricated.

The Candlemas Coal Co., of Silver Brook, near Hazleton, Pa., has begun the construction of a new anthracite breaker, which will be equipped with electrically operated machinery for an output of about 3,000 tons daily.

The Wilson Welder & Metals Co., Inc., will move its plant and general offices May 1 from 132 King Street, New York City, to the Wilson Building, Hoboken Factory Terminal, Hoboken, N. J. Increasing demand for welding machines and welding wire necessitated larger quarters.

Traffic News

Assigned-Car Order Date Now Set Back to Aug. 1

The Interstate Commerce Commission has again postponed the effective date of the assigned-car order, pending the consideration of evidence heard on rehearing, which resulted from protests against the Commission's original findings. Under the new order the rule becomes effective Aug. 1. The order was entered originally on June 13, 1923, and was to have become effective Sept. 1 last year. It was then postponed until Oct. 1, then until Nov. 1 and later until Dec. 1, 1923. The next effective date was Jan. 1, 1924. It was then postponed until Feb. 1, then April 1, and on March 3 the commission ordered that it should become effective June 1.

Railroads Must Provide Proper Facilities for Shippers

The U. S. Supreme Court on May 5 reaffirmed the principle that a state regulatory body has the right to require railroads to establish reasonable facilities for shippers and for the public. The case was an appeal of the Norfolk & Western Ry. against the Public Service Commission of West Virginia, which had directed the carrier to establish a crossing for vehicular traffic across its tracks at McCarr Siding, Mingo County, W. Va., near Blackberry City, the siding being primarily for the use of the Allburn Coal Co. A merchant of Blackberry City applied for the crossing order on the ground that he could not get a vehicle across the company's tracks to get freight consigned to him which was dumped at the siding. The state court's ruling upholding the order was affirmed.

Shipper Not Liable for Freight Except by Contract

A shipper is not responsible for freight charges unless there is an expressed or implied contract to this effect, the U. S. Supreme Court held May 5 in affirming the decision of the lower courts in the appeal of the Louisville & Nashville R.R. against the Central Iron & Coal Co., of Alabama. In 1917 the Central company sold ten carloads of coke to Tutwiler & Brooks. Before delivery, the latter sold the coke to the Great Western Smelter Corporation of Mayer, Ariz. Delivery to the railroad was made by the Central company consigned to Mayer, "on order of Tutwiler & Brooks." The smelter corporation paid \$5,082 freight charges, on demand when the coke arrived. It was discovered by the railroad three years later that the tariff rate was \$8,545 and an effort was made to collect the undercharge from the Central company, which resisted and denied responsibility. The Supreme Court held that shipment by the Central company "on order" relieved it of responsibility and that collection should be from Tutwiler & Brooks or the smelter corporation, neither of which had been sued.

Appeals Set Ahead

The Interstate Commerce Commission has advanced the dates for hearing appeals from the New England rate division decision. The case of the Central Railroad of New Jersey has been set for May 22; that of the Delaware & Hudson for May 26, and that of the Southern and Western carriers for May 28. The Jersey Central has asked for relief from contributing to the extra division awarded the New England lines. The Delaware & Hudson has asked, in addition to this, that the northern lines of its system be made beneficiaries of the decision, as are the New Haven, the Boston & Maine, the Maine Central, the Central Vermont and the Rutland.

Southwest Rates Are Reduced

The coal-mining industry of eastern Oklahoma and western Arkansas should be benefited by a decrease in freight rates provided for by an order of the Interstate Commerce Commission just announced at Washington. Reductions were not as great as were requested by the complainants, the Southwestern Interstate Coal Operators' Association. The rate now charged on shipments of lump coal from the Arkansas-Oklahoma group to Kansas City is \$3.28 per ton. The complainants sought a rate of \$2.49 and were granted one of \$2.65. Other rates from the various shipping points and to various destinations are in this proportion.

Coming Meetings

Retail Coal Dealers Association of Texas. Nineteenth annual convention, May 20 and 21, Vernon, Texas. Secretary, C. R. Goldman, Dallas, Texas.

Pennsylvania Retail Coal Merchants Association. Twentieth annual meeting and exposition, Commercial Museum, 34th and Spruce Sts., Philadelphia, Pa., May 22-23. Secretary, W. M. Bertolet, Reading, Pa.

International Railway Fuel Association. Sixteenth annual convention, May 26-29, Chicago, Ill. Secretary-Treasurer, J. B. Hutchinson, 600 Michigan Ave., Chicago, Ill.

The American Society of Mechanical Engineers. Spring meeting May 26-29, Cleveland, Ohio. Secretary, Calvin W. Rice, 29 West 39th St., New York City.

American Wholesale Coal Association. Annual convention, White Sulphur Springs, W. Va., June 3-4. Secretary, G. H. Merryweather, Chicago Temple Bldg., Chicago, Ill.

West Virginia Coal Mining Institute. Annual meeting June 3 and 4, Elkins, W. Va. Secretary, R. E. Sherwood, Box 1026, Charleston, W. Va.

The National Foreign Trade Convention. June 4-6, Boston, Mass. Secretary, O. K. Davis, 1 Hanover Square, New York City.

National Retail Coal Merchants' Association. Annual meeting, Hotel Virginian, Bluefield, W. Va., June 4-6. Secretary, Walter D. Rogers, Transportation Building, Washington, D. C.

Southwestern Interstate Coal Operators Association. Annual meeting June 10, Kansas City, Mo. General Commissioner, W. L. A. Johnson, Keith & Perry Bldg., Kansas City, Mo.

Illinois & Wisconsin Retail Coal Dealers Association. Annual meeting, June 10-12, Delavan, Wis. Secretary, I. L. Runyan, Great Northern Bldg., Chicago, Ill.

Illinois Mining Institute. Annual meeting, June 12-14 from St. Louis via boat down the river. Secretary, Martin Bolt, Springfield, Ill.

New Equipment

Newly Developed Single- and Three-Phase Motors

Two induction motors of a new type have recently been placed on the market by the General Electric Co. One of these is the single-phase constant-speed motor designed for operation on 40-, 50- or 60-cycle circuits and suitable for interchange on 110- or 220-volt alternating-current power lines. This motor is made in sizes varying from $\frac{1}{2}$ to 10 hp. Although designed on the squirrel-cage induction-motor principle, it entirely eliminates short-circuiting switches heretofore considered essential. Although the operating characteristics of this motor are similar to those of the usual induction motor, it has a high starting torque with low current demand. Both the maximum and accelerating torques are approximately 200 per cent of full-load torque without any low points during acceleration. The no-load and full-load speeds are both close to synchronous speed, thus the regulation is exceptionally good for this type of motor.

The stator winding consists of simple concentric polar windings arranged for double-voltage connections. The rotor consists of a cast squirrel cage winding and a repulsion wire winding of the multiple type with equalized commutator connections to insure uniform distribution of armature currents.

The new polyphase induction motor is designed for 60-cycle circuits and is made in sizes ranging from $\frac{1}{2}$ to 15 hp. It is rated on a 40-deg. continuous-duty basis. The electrical improvements embodied in this motor comprise reduced heating, higher efficiency and higher power factor at full and fractional loads and increased starting torque. The maximum torque ranges from 275 per cent to 300 per cent of its full-load synchronous value. The accelerating-torque curves are free from the dips common to most squirrel-cage induction motors.

The oil reservoirs on these motors have been enlarged from 50 per cent to 100 per cent. Other improvements in-

Improved Motor With Base, Pulley and Conduit-Box Connection

This new single-phase induction motor has unusually high starting torque at low current values. The maximum torque obtainable is nearly as high as that possible with three-phase motors.

Cast Rotor of Polyphase Induction Motor

This illustration shows the cast rotor of one-piece construction. It is claimed that this design eliminates the possibility of any high resistant spots in the winding.

clude a new method of directing the ventilating air to prevent dirt from settling on the windings, and a "cast" rotor of one-piece construction, having no joints nor high-resistant spots.

Stoker Controls Fuel Bed From Hopper to Ashpit

Many new and interesting features of design have been incorporated in the improved Taylor stoker manufactured by the American Engineering Co., Philadelphia, Pa.

Distributing rams of the old flat-end type have been replaced by a series of reciprocating pushers which form the bottom of the retort. This construction is said to give absolute control of the fuel bed from hopper to ashpit; it is claimed that it will keep the entire fuel bed constantly clean and free from clinker and give the full benefit of underfeed firing. Each ram can be adjusted so as to give a speed that is graduated throughout the retort so as to meet the burning characteristics of any fuel. Once these rams are adjusted for a particular kind of fuel, all further control can be obtained by a single adjustment at the front of the stoker.

Another new feature is a planetary-gear power box. This unit is claimed to be more efficient than the usual worm reduction gear. It has no clutches, yet it provides 50-per cent speed variation. Whenever it is neces-

sary to stop the stoker, the power box can be thrown readily into neutral position. An attachment to this box permits simple, positive adjustment of the distributing rams from the front of the stoker. The speed-control lever can be shifted from high to neutral or low speed with little effort.

TUYERES INDIVIDUALLY MOUNTED

The tuyeres are designed to change efficiently the static pressure of the air to velocity pressure and direct the air so that it is utilized to the best advantage. Each block of four tuyeres is individually mounted and can be removed without disturbing adjacent blocks.

Removable dead-plate tips are held in place by a key which can be taken out by hand. Just below the tips are reciprocating extension grates which are said to insure the burning of any fixed carbon remaining in the ash. It also assists in the control and removal of the latter.

The power dump swings above the horizontal to remove adhesions from the bridge wall. These plates are exceptionally heavy and can be removed by simply knocking out two keys. Ashes can be dumped and the wall cleaned in but a few seconds without any manual labor.

The front of the stoker is supported

New Stoker Varies Travel of Fuel on Any Section of Grate

Accurately machined parts, many of which are exact duplicates, control the fuel bed over the entire range of operation. The ram box is claimed to be non-sifting and can be renewed by the replacement of a few small parts.

on individual struts, accurately machined and designed to carry a front wall of any thickness and height. They transfer the load to steel work below the fireroom floor, thus eliminating the stoker channel in the front wall.

The stoker is built with from 15 to 45 tuyeres and a fire bed, even though long, can be accurately controlled by the distributing rams which are constructed of accurately machined duplicate parts.

Three-Cylinder Motor-Driven Air Drill for General Use

A lightweight non-reversible pneumatic drill suitable for light drilling up to $\frac{1}{2}$ -in. diameter holes, and reaming up to $\frac{3}{8}$ -in. diameter has been developed by the Ingersoll-Rand Co., No. 11 Broadway, New York City.

This is a light-weight drill which may be fitted with either breast plate, feed screw or grip handle and which thus is made adaptable for a wide variety of work. The construction of this machine is similar to that of Nos. 6 and 600 drills which this company developed two years ago and which were powered for drilling up to $\frac{3}{8}$ -in. diameter.

The features of this type of machine are briefly: light-weight aluminum case, with steel bushings cast in all the bearing holes and the throttle hole; cast-iron cylinders which are renewable and interchangeable and special three-cylinder motor. The renewable cylinders are a valuable feature, as any cylinder after long service, easily may be replaced and the motor made as good as new at slight cost.

The three-cylinder motor has the rotating parts all accurately balanced, eliminating vibration and reducing wear and tear on the machine. The drill is economical in air consumption and cost of maintenance, is high-powered, and, moreover, every part is readily accessible for inspection.

Lightweight Air Drill

The working speed of this drill is 700 r.p.m. when supplied with 90-lb. air pressure. It may be fitted with a breast plate, feed screw or grip handle.

Volume 25

NEW YORK, MAY 22, 1924

Number 21

JUST WHAT IS THE OUTCOME?

FROM start to finish the convention and exposition at Cincinnati was the largest and most important gathering of coal-mining men ever brought together in the history of the industry. The three-thousand visitors to Cincinnati, almost all of whom were closely connected with the coal business as executives, managers, engineers and financiers, canvassed its problems from coal face to markets. Many companies devoted much time and no little expense to attendance on the practical sessions and exhibits.

What is to be the outcome? If it is to be something more than a mere junket it should be followed by intracompany conferences. We hear much about vocational education for workmen and as to the value of a manual laborer spending his evenings in study. However, what we need as much or more is vocational study by the operating heads, conferences between them and discussions of their mutual problems. At no time is that more vital to success than after a conference and exhibit like that at Cincinnati. A clear conspectus was given at the Mining Show of the advance in mechanical appliances made during the past year and men got together and compared notes on their experiences in practical operation.

In too many companies the

story has gone the rounds that the "Old Man" is set in his ways and considers it his main duty to frown on innovations and cancel requisitions. The personnel consequently has viewed the whole problem of operation in a glum and disheartened manner, thinking that parsimony is more valued than economy and believing that a few men removed from the payroll would be more acceptable to the Big Boss than an increased tonnage per dayman employed.

Now is the opportunity for the executive to get together with the staff to remove that impression and to decide what changes must be made whereby costs may be lowered. Only those who make such changes can hope to continue in business. As has been said, "It is modernize or quit."

It is time, therefore, to call intracompany conferences, to revolutionize methods of operation as well as to wipe out inefficiencies which have been recognized by engineers for years but have been allowed to continue due to the division of authority, the aversion of some men to certain kinds of operating problems and to the feeling that the Great Boss is the "Big No" when any proposition is to be decided which entails the expenditure of money.

*Now, the Cincinnati meeting is over
—What is to be the outcome?*

Men with the Hoe

EDWIN MARKHAM'S sonnet on the "Man with the Hoe" describes most of us. We are held by the toils of our mutual relations so tightly that many of us cannot find time to look ahead and find out where we are going and which is the better way of getting there. Like the men in the woods we plunge too often in circles when an observation of the sun or of the moss on the trees might orient us and give us some chance of getting direction. Such a moment's opportunity was afforded us at Cincinnati. New tools to our hand, new ideas to our heads, new plans for our imaginations were provided. It does us all good to throw down the hoe long enough to think anew and plan afresh.

But too many, we fear, will go back and find their desks and mines cluttered with uncompleted tasks, and the will to think, to plan, to consult and to advise will die aborning. How many a strong man has been overborne by routine, by the multiplicity of meticulous duties, by a flood of work that fills from meal to meal, from rise to set of sun! Many a man rested, given opportunity and a little pause for thought might do by planning and machinery what now he does inefficiently by brute force.

Are You a "Mud Horse"?

MANY a running horse can make speed over a good track. It takes stamina to lead the race over a muddy course. Too many of our operators attain their best form when the going is good. It is a real success only when results are obtained under unfavorable circumstances such as are now confronted. The mud horses that make headway in unfavorable weather are now leading the race. Efficiency, system, foresight and a certain venturesomeness in directions not charted put them in the lead. Given high prices and unlimited demand, some men show speed and courage, but given a depressed market, they fail utterly. These difficult days prove one's staying qualities. Where others give up in despair, the men of real constructive genius change their methods, adopt new machinery and stay in the race.

It's All in the Feed

A few years ago, when the electric storage-battery locomotive was first placed on the market, many engineers were dubious of its possible success. One objection raised was the small capacity of the driving motor. The claim was made that its horsepower was too low for the size of the locomotive. Some engineers said that the manufacturers would go through a development period and gradually increase the motor capacity until it would be somewhere near ten or twelve horsepower per ton.

The years have rolled by; many mules have been replaced; in fact, in some mines it would seem strange to see a mule. The storage-battery locomotive has won its place.

Strange to say, its motors have not been greatly enlarged, yet the locomotive has been a success. What is the secret of the small motor? Is it not that the speed of the storage-battery locomotive is slower than that of the trolley locomotive? There is, however, another reason; the storage-battery locomotive carries its own power plant with it, and consequently the voltage drop between the battery and the motor is nil. The motor receives nearly full rated voltage all day. Does

not this indicate that motors supplied with proper voltage will do the work of larger motors which receive low voltage? Then why not reduce the resistance of feeder circuits, install and maintain good bonding, put the direct-current power converting equipment nearer the load centers and make the substations automatic?

Outside Looking In

ANY industry is likely to be so absorbed in its own viewpoint that it cannot see its own woods for the trees. The coal industry is no different from any other in that particular. So it was refreshing to see that the National Coal Association at its convention in Cincinnati more than half filled its program with outsiders. They said things that made two points clear: First, that some of the thinking men of this country outside the coal industry are just beginning to get a true perspective of coal and its major problems and, second, that it is worth while, after all, to meet the public at least half way so that more thinking men can get that same perspective.

It did 300 big coal men good to sit still and hear R. S. Kellogg, secretary of the News Print Service Bureau—an utter stranger to coal—tell them in brisk, interesting style that he believes organized coal men can do much for their industry along trade-association lines and just how he thinks they ought to work. He knows trade associationism and he is just beginning to learn enough about coal to be able to apply his fundamental knowledge to it. His was an outside viewpoint and he surprised many a man wise in coal by showing him that an outsider can think soundly about the bituminous-fuel industry. If some man well known in coal had voiced the same thoughts with equal authority and force, those thoughts would not have registered so deeply on the association.

It was good also that the viewpoint of the retailer was brought in, and of the expert merchandiser and of the head of the world's greatest news-handling agency. Such men as those are outsiders but they are men of the types which count heavily in making up the public mind about coal. The outside viewpoint is a good thing for the coal industry to get. In getting it the industry will learn better how to maintain its public relations.

Why Work in the Dark?

THE public utility power companies once sold electrical energy and only metered that which the consumers used. They didn't know how much power was generated, how much was lost, neither did they know the boiler efficiencies or the cost of distribution. With a blind faith in the possibilities of electric power they struggled on—and some were successful.

A day came, however, when the leaders realized that if profits could be made in ignorance and darkness, better returns could be obtained by a thorough knowledge of power generation. Meters were used, records obtained and studied until now every up-to-date power company official has operating data on every detail of manufacture and distribution.

The advantages of electric application to mining have been so obvious that even some of the largest coal companies have no data upon the operating characteristics of their most important machines. There may be no question about the fact that this electrically driven equipment is saving money, but cannot better results be

obtained? A thorough survey of present electrically operated apparatus may prove it to be more efficient than the officials believe. Should it so prove it will more quickly spur them to further modernization.

A hoist may be causing continual interference with other equipment by peak loads which open the main-line fuses. If that condition is known it may be corrected. A few underloaded induction motors may be using up all the kilovolt-ampere capacity of a transformer bank and necessitating the purchase of larger transformers. Knowing the cause of trouble induction motors of the right capacity can be installed. The high equipment maintenance costs may be due to low voltage on the supply lines. A feeder line may correct this evil when discovered. Perhaps also an examination will show that the motors you are purposing to replace with others are of ample capacity for the work, if the proper voltage is supplied.

Now it is time to turn on the light, obtain test data and find out the facts about transformers, motors, substations, power houses, transmission lines and distributing systems; to effect savings in operating costs, power bills, capital charges, etc.

Economy in Transportation

THOUGH loading machines and conveyors are essential to utmost economy, continuity in operation will produce an important decrease in costs secondary only to that effected by mechanical loaders and belts, scrapers and shaking chutes. With such equipment, it is true, operating continuity is of paramount importance, but even with hand loading, operating without delays is productive of economies that cannot be safely overlooked.

Operators are beginning to realize this, and as a result switches and frogs, mine cars and locomotives that operate without derailments are making remarkable headway. As at the recent exhibition at Cincinnati the loading machines were in a tent in the rear of the hall it was a little difficult to realize that the exhibit was a mining show, so prominent were the booths devoted to transportation. That phase of mining seems to be thrusting itself more and more on the attention of mining men. One can almost foretell the time when every mine will have its transportation engineers who will be responsible for equipment that will keep the mine working steadily without the waits that derailments and breakdowns inevitably cause.

Heavy rails and ties that will not give and break the electric bonds; switches that will be of correct gage throughout and switch points that will not break at the ends, that will close tight and not derail cars or locomotives; frogs that will retain their shape, wheels that will not wobble or become loose, that will not develop false flanges or flat spots; bearings that will run with minimum wear; cars which have strong but flexible frames, all are means to the final end.

Mines are miniature railroads, and not so miniature after all. The absolute need for continuity of operation makes it necessary for every coal company to regard its transportation problem as of paramount importance. Heavier cars and higher speeds are making new standards necessary. No one can foresee where the increase of car size will end. Already where cars enter rooms five- and even eight-ton cars are being constructed. Where cars are not transported to the working place, they may be made far bigger, and if by an extension of the conveyor system, all the coal is transported to

the main haulageways, they may be made even larger still.

There is hardly any limit to the size mine cars may attain with such a system of loading. We might even take railroad cars into the mine were it not that when they are brought to the surface they must be dumped so that the coal can be cleaned on picking tables. Where the coal is clean, however, and top and bottom material does not enter the product, such cleaning would not be necessary. Sizing, if demanded, could be done with advantage at the receiving point, thus eliminating from the screened sizes the coal that is degraded in railroad transportation.

Where Is the Nationalization Noise?

FOR some reason the great clamor for nationalization of coal mines has subsided during the past several months. What is the reason? Can it be that the coal industry has at last done so good a job of producing coal and delivering it to the people of the country at a reasonable price that everybody is satisfied? The industry certainly has been doing that sort of producing and delivering, and if public satisfaction has been the result, then let the coal man congratulate himself if he can, as he anxiously scans his bank balance to see if he can pay the rent without fear of overdraft.

But everybody is not satisfied. There is no use expecting that, no matter how well the industry has done its job lately. In spite of the fact that the price of coal to the consumer is lower now in proportion to producing costs than it ever was in history, there are buyers who are not satisfied and are waiting for it to go lower. *Coal Age* index on the prices of all important soft coals throughout the country had sagged down to \$2.05 the week of May 5 and we hear of eastern Kentucky contract mine run at \$1.65 with spot mine run of that region bringing \$1.25! It costs a good deal more than \$1.25 to buy a ton of dirt for the garden. Yet part of the present slackness of the market is due to the fact that "these coal fellows may have to give it to us for less yet." At this rate of buying, next fall is going to see a strong call for coal, a car shortage, and prices somewhere above the cost of production. Then listen for the clamor. There will be the voice of the nationalizationist abroad in the land.

Secretary Hoover, speaking at Cleveland, May 7, said nobody wants government control of the bituminous coal mines any more. And he is correct—for the present. The elaborate plan which a special committee of the United Mine Workers prepared, telling the country "How to Run Coal," didn't even get a good airing in the miners' international convention last February. When the cry for nationalization doesn't sound in Tomlinson Hall, Indianapolis, then it doesn't sound anywhere—except down among the coal miners of Greenwich Village. So it is true the demand for both government ownership and control is dead.

It is dead because, for once in recent history, there has been a glut of coal for almost a year. The operation of the glut on the coal business has been far from painless, but at least the coal man has rid himself of one worry—the public demand for Uncle Sam to seize the bituminous mines. The chances are this demand will never again become insistent in view of the general world-wide failure of government operation of public utilities. But we may confidently expect to hear voices on the subject as soon as the industry again becomes a going concern with a profit in the price of coal.

Electrical Engineers Discuss Ways in Which Savings in Power Cut Mining Costs

Applying Storage Batteries to Cutting Machines and Main Line Locomotives—Economy of Multiple-Speed Fan Motors—Voltage Regulation—Standardization—Inspection—Testing

Can the Sparking Trolley Be Eliminated?

IMPROVEMENT of electrical methods in coal mines so as to increase safety was advocated in a meeting of the American Mining Congress held on the morning of May 12. R. L. Kingsland, electrical engineer of the Consolidation Coal Co., described the efforts being made by that company to increase safety in a gaseous mine by the use of storage batteries for coal cutting and main-line haulage. The practice in the past, he explained, had been to use compressed air in gaseous mines as motive power for haulage. He said that the company had attempted to standardize the voltage for cutting machines so that standard motors might be used drawing their energy at 220 to 250 volts which is the standard voltage. This makes it readily possible to use standard equipment for charging batteries. For the past year an arcwall mining machine has been used operated by power furnished by a battery truck containing 117 lead cells, storing 80 kw.-hr. of energy. The battery truck runs on its own power but it has no extra power for haulage purposes. A 30-hp. motor with double reduction gear, chains and sprockets is used. The power consumed per ton of coal mined averages between 0.2 and 0.25 kw.-hr. operating in the Pittsburgh seam.

The company believes that from 20 to 24 places can be cut by this machine in eight hours and that it can be done more cheaply by storage batteries than by current from the trolley.

A main-line storage-battery locomotive has been in operation for three months. This locomotive is provided with two batteries with the intention of running it a full shift of eight hours

using one battery for the first four hours and the other battery for the period after the midday suspension. This will be necessary if the locomotive is to have full power for the whole eight-hour shift.

The locomotive weighs six tons, each battery containing 117 lead cells and having a capacity of 108 kw.-hr. It delivers current at an average potential of 225 volts. This gives a total current capacity of 200 kw.-hr. for each eight-hour shift. The locomotive is equipped with two 250-volt motors. The average length of the round trip is now 8,400 ft. It hauls sixteen mine cars, each having a capacity of from 2 to 2½ tons.

MORE POWER HAULING THAN CUTTING

The power consumed per ton of coal hauled is less than that for cutting the same quantity of coal. To date it has been necessary only to use one of the two batteries for the entire shift. In the near future, however, with the increase in the length of the round trip it will be found necessary to use both the batteries. The longer the haul the more power is used because the time lost at the bottom and side track does not change with the increased length of distance traveled and so a locomotive with a short haul loses a longer period in delays and does not use as much current as one with a longer haul which is more of its time traveling on the road.

It will be a difficult problem to get a battery big enough to supply power to haul coal a distance of two or three miles. Up to a two-mile haul it is entirely practical to get two batteries which will do all the work of which one locomotive is capable. Mr. Kingsland added on being questioned that the life of the batteries is closely that guaranteed by the manufacturers.

R. D. Hall, engineering editor, *Coal Age*, described the equipment for haulage which the Phelps Dodge Corporation proposes to install. This has already been published in *Coal Age* in the issue of May 1.

Graham Bright, of Howard N. Eavenson & Associates, said that the conditions at the Phelps Dodge operations were different from those at the Consolidation mine. As he understood it the locomotives at the Phelps Dodge operation were to come to the surface and be operated on the trolley whereas Mr. Kingsland's were kept underground. Consequently the Phelps Dodge locomotive could be charged while on the surface, whereas such a source of power was not available to Mr. Kingsland. This would make it possible for the Phelps Dodge Corporation to get heavier service from the locomotive than it could hope to get if the battery could not be charged in the manner described.

OTHER ADVANTAGES POINTED OUT

L. C. Illsley, electrical engineer, U. S. Bureau of Mines, said that storage-battery locomotives and mining machines had advantages that had not been discussed by Mr. Kingsland. Where the trolley system was used the electric current could not be under close supervision especially at night and at other times when the mine was not under operation. If the trolley wire was alive at such times accidents might happen with no one present to shut off the current and correct what damage might be done.

Mr. Detweiler said that he feared that even if storage-battery locomotives were used a dangerous condition might result should a wreck occur, especially in the presence of a cloud of coal dust.

Mr. Kingsland declared that batteries had such heavy and strong jars that they would stand considerable violence without serious injury. In wrecks of storage-battery locomotives they had never had any fires. Though some hazard undoubtedly existed it did not approach that accompanying the use of a trolley locomotive.

Graham Bright said that, of course, such equipment could not be made hazard-proof. One item in favor of the safety of the storage-battery locomotive was that it traveled at a slower speed than the trolley locomotive and that made wrecks less frequent. A roof fall was another source of danger but only in the presence of gas or dust.

C. L. Harrod, electrical engineer, Indiana Coal Operators' Power Association, said that he had made a test showing that the power cost was one cent per ton lower with the trolley type of locomotive than with the storage-battery type. Mr. Kingsland said he had not made any careful tests, but he thought the input to the storage battery would be less or at least little in excess of the input to a trolley locomotive. He believed that the advantage of using the off-peak current would make the use of the storage-battery locomotive advantageous. Mr. Harrod said he gave no consideration in his test to the period of the day during which the current was taken from the line. The mining company merely wanted to know the relative quantity of current used. All current was figured at 2c. per kilowatt-hour, and the outcome showed that the trolley locomotive gave a rate 1c. per ton lower than the storage-battery locomotive. He did not suggest that this would be universally true but only that it was true in the case he investigated. The batteries were in first-class condition when the test was made. The mine had several steep grades.

Mr. Kingsland, questioned as to the power used per ton hauled, referred to what he had already said and stated the efficiency of a storage battery was not much better than 50 per cent but that of the wiring in most mines was considerably less. The trolley would

show up the better as regards the use of power from the kilowatt-hour standard but on the other hand the storage battery gave the better load factor.

W. Van C. Brandt, manager Power Battery Division, Electric Storage Battery Co., said that the current used in the charging of storage batteries depended on the way in which they were charged. It is possible to waste current in charging if the right equipment is not provided and if the equipment thus installed is not properly used. A storage battery has an efficiency of 72 per cent if you measure the energy at the battery terminals. If you convert the power supplied a lead-cell battery you have another loss in

Can Save Power by Slowing Multiple-Speed Fan Motor

IN his address A. B. Kiser, electrical engineer of the Pittsburgh Coal Co., emphasized the value of variable-speed motors for fans where conditions made the use of several different speeds desirable. He said such fan motors were advisable because they enabled the speed of the fan to be regulated, (1) so that the quantity of air could be adjusted to the needs of the mine when in full operation, (2) so that the speed could be reduced during the night, on idle days or during slack operation, (3) so that the ventilating current could be increased when required, (4) so that the circulation of air could be greatly reduced in case of a mine fire and (5) so that the speed could be regulated to meet the demand whenever the ventilating system is revised.

Whenever such a motor is used the fan has all the advantages obtained when driven by a steam engine. The saving effected by the use of variable-speed motors can be illustrated best by examples. Assuming 306 working days per year at a mine and that the speed of the fan can be reduced from 4 p.m. to 2 a.m. when the firebosses enter the mine to make their examinations. The fan will then operate for ten hours at reduced speed or for 3,060 hr. during the year. Sundays and holidays comprise 59 days in the year or 1,416 hr.

converting apparatus. More attention should be given to the method of charging. In a recent instance a company had invested \$45,000 in charging equipment and was expecting with reason to get that investment back in the savings made within a year from installation. With the old manual control it is possible to overcharge your battery and use more current than you actually need. By the constant-potential method the exact amount of current required by the battery is fed to it and at the end of that time the current is automatically shut off. When your power costs are too high it will pay you to look into your charging equipment and methods.

Adding these together, the speed of the fan may be reduced for 4,476 hr.

A 6x3 ft. fan circulating 100,000 cu.ft. of air per min. against a 3-in. water gage when driven at 305 r.p.m. would require 51 kw. at the fan. Reducing the speed to 209 r.p.m. and diminishing the volume of air in circulation accordingly, only 26 kw. would be required. This saving of 25 kw. for 4,476 hours would represent 111,900 kw.-hr. which at a cost of 1c. per kilowatt-hour would cost \$1,119 per year.

Taking a larger fan 16x6 ft. producing 500,000 cu.ft. of air per min. at 5-in. water gage and running at 137 r.p.m. the energy required would be 525 hp. A 10-per cent reduction in the speed of such a fan during the slack period would save 102 kw. This is a yearly saving of 456,552 kw.-hr. which at a cost of 1c. per kilowatt-hour would make a saving of \$4,565.52 per year.

At many mines a disk fan can be used operating at a low water gage. Assuming that such a fan is 8 ft. in diameter and circulates 100,000 cu.ft. of air per min. at a 1-in. water gage, running at 353 r.p.m. it will require 32 hp. If the volume of air is reduced one half, or to 50,000 cu.ft. per min., the saving will be 21 kw. Assuming that this saving is for 4,476 hr. it will aggregate 93,996 kw.-hr. and at 1c. a kilowatt-hour the saving in cost will be \$936.96.

MOTOR SAVED \$3,065 IN YEAR

During 1923 many mines ran short time. One mine was fitted with a fan driven by a variable-speed motor. When on high speed the fan required 65 kw. or 569,400 kw.-hr. per year. As a matter of fact the speed was reduced and only 262,856 kw.-hr. were used. Thus 306,544 kw.-hr. were saved. This was a saving in cost of \$3,065.44.

Another mine has a fan running at high speed requiring 118 kw. The fan was operated at 128 r.p.m. In the course of a year such a fan would need 1,033,680 kw.-hr. The power actually used was 785,720 kw.-hr.; and the saving in power was 247,960 kw.-hr. which at a charge of 1c. per kilowatt-hour would be equivalent to a saving in cost of \$2,479.60. This mine has been idle since the first of the year.

At another mine the quantity of air is reduced during idle periods to 175,000 cu.ft. by operating the fan at 130 r.p.m. instead of 154. The difference in power required is 39 kw. As the reduction in speed is for six hours in every twenty-four the saving is 234 kw. or \$2.34 per day, or figuring in Sun-

Fig. 1—Storage Battery Haulage Locomotive

In many mines storage battery locomotives are used to accomplish two results—first, to avoid the danger of gas ignition and second, to equalize the load on the power plant. In addition to this, however, the accumulator locomotive is a self-contained unit and can travel anywhere in the mine where track is available.

days \$98.10 per month. The Pittsburgh Coal Co. has 70 fans in operation. Of these 65 are electrically driven, 59 of them having variable-speed drives. Five fans are steam driven. Ten of the fans are 250-hp.; six are 150-hp., the rest 75-, 40- and 20-hp. fans.

Graham Bright said that the subject introduced by Mr. Kiser was two-fold: (1) Is it desirable to reduce the ventilation during idle periods? and (2) If it is desirable what type equipment should be used for that purpose?

J. H. Edwards, electrical engineer, Elkhorn-Piney Coal Mining Co., said that one of the company's mines was ventilated by a 3x7 ft. fan that had been running for fifteen to twenty years, twenty-four hours a day. The power bill for that fan was about \$600 per month. The energy supplied to this fan motor was metered and a few years ago the company sought means to reduce the cost for running fan when the mines were shut down.

At an expense of \$800 a small horsepower motor was connected to the fan. By running the fan at reduced speed, with the small motor, when the mine was not operating at full capacity or was not working at all a saving was made amounting to \$300 per month. It is easy to see the large saving that could have been made if this had been done earlier. The company continued this slowing of the fan for a year or more and even at night during the regular operation of the mine. Lately it has been thought better not to slow down the fan.

Mr. Bright remarked that whether it was advisable to slow down the fan or not depended upon circumstances. Where a large fan is used this is an important question as large quantities of energy are involved, and any advantage should certainly be taken if conditions permit. Mr. Kiser is using a variable-speed motor, but there are two-speed motors which do not give such a wide choice of speeds but nevertheless might serve the purpose. The motor with two speeds in the ratio of 2 to 1 is much simpler than the variable-speed motor.

FREES METHANE AND REMOVES IT

W. H. Luxton said he believed there were some advantages with a variable-speed motor. In a mine ventilated by a blowing fan the workings are under pressure. Any reduction of that pressure allows the gas to escape into the roadways where it can be removed by the fan. With a steady pressure this gas has less opportunity to flow to a point where it can be driven out.

J. F. MacWilliams said that he believed that inquiry should be made in every case to ascertain whether two speeds will serve or whether a number of speeds are necessary. With a variable-speed motor you get a power factor of 58 per cent at 350 r.p.m.; 92 per cent at 550 r.p.m.; then starting on the second connection of the motor 75 per cent at 550 r.p.m. and around 94 per cent at 750 r.p.m. If it is necessary to have a number of speeds this is the type motor to be used. If two speeds will meet your need you can use a motor that at 695 r.p.m. will give you 90 per cent efficiency. At about 335 r.p.m. it gives 40 per cent efficiency.

The power factor of the brush-shifting motor is 54 per cent at 335 r.p.m. At maximum speed, when Y connected, the power factor is 94 per cent and then drops to 75 per cent at slow speeds, when delta connected, and increases to 97 per cent at maximum speed.

Mr. Mitchell said that if a mine generates gas it is necessary to keep it well ventilated. To slow down the fan might result in the ventilation being reduced to such a degree as to not make the gases harmless. If the company using the fan is not operating a gaseous mine there is no need to operate the fan when the mine is idle. Consequently it is first of all necessary to determine what is the object of the fan, to make the mine safe or to furnish the men with sufficient air. If the fan is run to make the mine safe, the fan can be shut down when no men are in the workings.

Mr. Bright in his comments remarked that the first object should be to keep the mines safe at all times and added that if that could be done with the fan running at half speed provision should be made to take advantage of that economy.

J. O. Durkee, of the Bethlehem Steel Corporation, said that men were more lax during idle times than when the mine was operated continuously. Consequently it was his opinion that the gaseous mine should be better ventilated when idle than when working. The Bethlehem Steel Corporation has

seven mines closed down at present. The company had some mines where with 1,000 cu.ft. per man in the mines and 70 per cent of the air reaching the working faces, the return tested 4.7 per cent methane. If such a mine were idle but had pumpers working in it, it would be suicidal to reduce the fan speed. He had noticed that many disasters had occurred as a result of reducing the speed of the fan. The great gaseous mines of Pennsylvania and West Virginia should have about the same volume of air when working as when idle.

C. L. Harrod, electrical engineer, Indiana Coal Operators' Power Association declared that in Indiana, the quantity of air required was based on examination of the gas in the return. He thought that the fan speed should be reduced at idle times provided that the speed reduction was never so great as to reduce the ventilation below the limit of safety.

R. L. Kingsland said that the efficiency of ventilation was greater by 5, 10 or even more per cent at night than during the day when the mine was working because doors were not opened and trips did not interfere with the passage of air. This was one reason for favoring the use of the variable-speed motor. Another was that certain external atmospheric conditions were favorable to ventilation and when they were available less assistance from the fan was needed.

Put Rated Voltage at Face and Lower Power Costs

A LOSS of \$410,000 in power alone, further losses from burnouts and consequent repairs and still further losses from delayed operation were mentioned by Carl Lee, electrical engineer, Peabody Coal Co., Chicago, Ill. as reasons for renewed effort on the part of every operator to put the rated voltage at the mine face thus lowering power costs.

"The power and maintenance cost of electrical equipment around our mines is not a large percentage of the total production cost of coal. Once the miners' wage rate is set, as it now is for a period of three years, there is no honest reduction that can be made in that item and it therefore becomes necessary to consider other ways to reduce the cost per ton.

Statistics indicate that the use of electricity in coal mines is increasing at a very high rate. Accurate figures on the number of motors, mining machines and locomotives are hard to obtain, but can be approximated. Correct figures on electrical power consumption are not obtainable because a large percentage of mines do not meter their power, and, in fact, many coal companies do not even weigh their boiler coal. However, by using the data that is available we can arrive at reasonably close figures.

Taking a general average of hard and easy cutting, high and low coal, the power used will probably be about 0.40 kw.-hr. per ton. If 50 per cent of the coal is undercut, then there would be 100,000,000 kw.-hr. used annually for that purpose.

With gathering locomotives there is a very wide range of conditions encountered. Different grades, sizes of cars, kinds of bearings, methods of handling, types of locomotives, all effect the power consumption per ton. Possibly 0.25 kw.-hr. per ton would be somewhere near the general average. If there are 100,000,000 tons gathered at this rate, then 25,000,000 kw.-hr. would be used.

Haulage locomotives present a complex problem because of very widely different conditions. With improved track and modern locomotives the power used per ton is low, about 0.20 kw.-hr. for a general average. A large percentage of all the coal mined is hauled with electric locomotives, and therefore, assuming 400,000,000 tons hauled at 0.20 kw.-hr. per ton, we find that 80,000,000 kw.-hr. are required for this purpose.

Omitting pumping and all other inside power loads, there would be about 205,000,000 kw.-hr. used annually for bituminous coal production alone. At 2c. per kw.-hr. this would cost \$4,100,000. If the average loss is 10 per cent there would be \$410,000 loss in power alone. The loss in production and the added cost of maintenance would probably be a greater item.

At the outset, however, we must realize that we cannot afford to make the feeders large enough to carry all this power from the generators to the motors with the same efficiency as is used in industrial plants or home lighting. There are several reasons for this. The principal one is the long distances and heavy currents which make the losses excessive. Then again, the load factor is generally low. Even

during the day the load factor will be as low as 50 per cent or less. The 24-hour load factor would then be only 16½ per cent and the yearly load factor possibly 10 per cent. Thus the ratio of the average use of the copper for a year to the use at the peak load is 10 per cent.

However, the electric service must carry the peak load and our problem today is to find how to reduce the losses to the point where the total cost will be a minimum. In a large majority of coal mines the wiring is smaller than required to give a reasonably low total cost.

First, there is a loss due to drop in voltage. This is a direct power loss in the wires and motors. Second, there is a loss due to armature, field, and rheostat burnouts caused by low voltage and consequent repair cost. Third, there is a loss of production which affects not only the investment tied up in the electrical equipment, but all other parts of the mine. This is probably the greatest loss of all. These three principal losses are a direct result of insufficient copper, or its equivalent, to carry the necessary amount of power from the generators to the motors. The proper method of calculating the size of copper necessary and the right tests to use to check such calculations for new mines, or all mines where the circuits are already installed, is a serious and difficult problem.

KEEP DIVERSITY FACTOR IN MIND

Using the nameplate ratings of motors is good if properly applied. Ohm's law for estimating voltage drop must be the basis of all our calculations, but due allowance should be made for the diversity factor and demand factor of a single motor or group of motors. The size of the wire used in various circuits depends greatly upon the load, but is not directly proportional to the connected horsepower. We should try, therefore, to formulate general rules from which the hundreds of engineers and electricians at our coal mines can check the wiring and arrive at more accurate results.

Articles have appeared a number of times in the columns of our trade journals explaining how to make voltmeter tests on complete lines of wires. Such tests can be made accurately, but in most cases, I do not believe that they will be of any material benefit. In my opinion, a test on the return circuit should be made by an individual joint or bond test. The defective bonds can then be marked, and repaired or replaced as that is the only real remedy."

At the conclusion of Mr. Lee's remarks Graham Bright asked what is a permissible drop in voltage. Mr. Lee replied that the allowable drop depended on circumstances. If on a line there were several gathering locomotives and mining machines, the voltage drop should be kept at a minimum, for at all times some of these would have motors running. It would be a waste of power not to give them a good line voltage, but it is different where you have an individual motor which at times makes unusual demands on the line. If, for instance, you have a single locomotive and there is no pump or other machinery to make a regular

Fig. 2—Substation at Load Centre Underground

Low voltage is the incubus of mine haulage. Carrying high-voltage alternating current underground to a substation located at a load center improves the pressure, cuts down the necessary investment in copper and reduces locomotive repair bills.

draft of energy from the line, then if the voltage drops to 50 for a few seconds, the loss is heavy on that one unit but it will be so for a short time and for only one machine. Consequently it will not pay to install a feeder cable. If, however, we had six units drawing from the line and one of those six could be depended on to be working all the time then a heavy drop in voltage should be avoided by providing a feeder.

Mr. Bright said that the permissible

voltage drop was a matter of compromise. The cost of copper to eliminate all excessive voltage drops would be so great as to be prohibitive.

J. H. Edwards remarked that he agreed with Mr. Lee. His experience urged him to measure the voltage at a main distribution point. If a graphic voltmeter is put on such a line the average value for a working day can be obtained and a figure should be set for a proper average at that point.

How a Bulging Stock Room Beggars Its Owner

WHAT advantages can be obtained by shifting equipment from mine to mine so that each mine will have but one type of any one kind of machine and not a number of different types was explained by J. H. Edwards, electrical engineer, Elkhorn-Piney Coal Co., Huntington, W. Va., who had made full proof of these advantages in the administration of the electrical affairs of his company.

In Mr. Edwards' point of view the engineer who is responsible for the design and installation of electrically driven equipment is very apt to have a viewpoint on the subject of standardization much different from that of the engineer who must operate the apparatus in the most economical way consistent with the delivery of reliable and continuous service. Therefore, it may be well to approach this subject from the viewpoint of the electrical engineer, who is responsible for all phases of design, construction, and future maintenance; his attitude should represent what is best for those who have their money invested in the coal mining industry.

In the first place, standardization must not stand in the way of progress. It appears that it will not; for any tendency in that direction will be taken

care of in a natural way. When present types of machinery prove unsatisfactory for their changed or increased duties, or are known to be inefficient, the operator casts about for improved designs and the manufacturer continually has an incentive for trying to perfect his product. The manufacturer also knows that a new piece of equipment with real and proven merit is sure to have a ready sale, regardless of what has been the standard in the past.

The most important phase of standardization is simplification of equipment and operating methods within individual companies. Any maintenance engineer or other mine official can easily point out many instances where improvements have been made possible by lack of standardization. The many advantages of having in a single mine, in a division, or in a large group of mines, as few types and sizes of equipment as is consistent are so apparent that it seems hardly necessary to enumerate them.

It might be fitting at this point to cite a specific case of what a company operating a group of six properties accomplished in one year by concentrating attention upon standardization. By transfers from one property to another, by selling, and in a few instances by scrapping, this company eliminated nine types of mining machines and seven

types of locomotives. This does not mean getting entirely rid of each type, but rather eliminating certain types from mines where there were only a few of a given type or size. This, of course, made possible the elimination of sixteen sets of spare parts.

The total standardization of all equipment, including the above mentioned mining machines and locomotives resulted in a reduction of over \$45,000 in the value of spare parts carried in stock. Very few pieces had to be scrapped; most of the reduction was effected by transferring parts to other properties. The above figure represents only the most tangible saving effected by standardization. It represents only a minor part of the total actual yearly saving in operating expenses.

Figures indicating the amount of spare parts per ton of coal mined are often an indication of the degree of standardization. For the group of six mining operations mentioned above the actual figures were as follows:

Operation	Before Standardization	After Standardization
No. 1...	\$25.00	\$14.57
No. 2...	27.20	9.52
No. 3...	27.80	10.72
No. 4...	22.00	8.34
No. 5...	25.10	8.34
No. 6...	6.42	7.58

Note—These figures were obtained by dividing the total value of the stock of spare parts by the maximum daily tonnage.

It is concluded from the above that figures of \$5 to \$10 are to be expected, depending of course on the specific conditions. Electrical men connected with coal mining are liable to conclude that standardization is limited to equipment only. Standard methods of installation, periodic inspection, and of repair and part renewal go hand in hand with standardization of equipment toward the goal, of lower cost per ton.

CAN'T KEEP EQUIPMENT STANDARD

In discussing Mr. Edwards' paper T. H. Huddy, general manager of the Sudduth & Bailey Fuel Co., asked if it was possible to standardize equipment and keep it standard. Mr. Edwards replied that his company's standardization had been in effect only a short time. He would say that he did not believe that standards could be maintained indefinitely.

Eli Clemens, electrical engineer, U. S. Coal & Coke Co., said that it was important to standardize motor speeds. If the motor on a stationary machine breaks down it is convenient to be able to take a motor from some other machine and set in the place of the damaged one, so that important machinery can be kept in operation continually. The U. S. Coal & Coke Co. has standardized on certain speed motors with this idea in mind.

Mr. Newton remarked that he had been able to reduce the expense of repair parts by standardization. Seven or eight years ago his company had five or six types of mining machines and an equal number of types of locomotives. About \$250,000 were invested in extra parts, located at different mines. In some cases it was necessary to keep duplicates of parts. After standardization it was found possible to reduce the supply parts so that the stock rooms carried only \$50,000 worth

of stock and yet there were available sufficient repair parts for every machine.

Mr. Bright said that when a company had standardized its equipment it was more likely to provide the necessary replacement parts than if it had a great number of types in use. The expense of carrying a large number of parts is prohibitive.

Mr. Bailey said that standardization of equipment increased the efficiency of the employees. Having only a few types to operate and keep in repair they soon became expert in their handling.

Watch for Breakdowns Before They Affect Your Purse

IN INDIANA the operators have an association, known as the Indiana Coal Operators' Power Association, of which C. L. Harrod is the electrical engineer. He gave an interesting account of its manner of operation, describing how it reduced the power bills of those who maintained it.

He said that the cost of mining coal can be lowered by a survey with the following purposes in view: Improving power supply by bettering distribution, eliminating unnecessary power losses, reducing maximum demand and raising the power factor, reducing the time losses and repairing costs resultant on breakdowns and failure of power supply, eliminating inefficient equipment.

Mr. Harrod said the association had for the past three years attempted to make its electric inspections systematic, and to that end had prepared recently a printed inspection sheet to be filled out by the man making the inspection, a copy being filed with the association and another with its superintendent.

The form divides the inspection of electrical equipment into two parts, that which is a part of the routine of the inspectional forces and is made at least once a month, and that which may be designated "testing." Mr. Harrod referred in his remarks to the first subject only so as not to interfere with J. F. MacWilliams' subject "Testing of Electrical Equipment" which was to follow.

INSPECTORS ANSWER QUESTIONS

The routine inspections cover the following points: Lightning arresters—are they intact and properly grounded? Protective signs around high-voltage mains—are they in place? Foreign or inflammable material—is any stored near switchboard or other electrical apparatus? Exposed wiring—does it conform to insurance regulations? Converter equipment—does frame vibrate? Is there sparking at collector rings? Is there sparking at the commutator? If direct-current circuit breaker is not higher than rated capacity of machine, determine, if possible, how often breaker opens. Fan—give revolutions per minute; if two-speed motor is provided are both speeds used? If variable-speed motor is used, on what controller point is fan normally operated? Do grids heat when normal speed is exceeded? Metering equipment—does demand-chart ink properly?

Does demand-chart indicator return to correct zero at end of fifteen minutes? Does watt-hour meter creep? Is direct-current voltmeter correct at 250 volts; if not what is error? Have power company employees done any work on metering equipment during last month? Electric hoist—is safety stop properly set?

The inspectors also report on tippie motors, car hauls, miscellaneous equipment above ground, the condition of the feeder wires in the shaft, the condition and setting of main underground circuit breakers, repairs to haulage motors and mining machines. They make a ground test of the system and voltage tests during operation. They also examine the bonds.

The greatly increased volume of power used in coal mines and the increase in the value of coal consumed in mine power generating stations make it more and more imperative that every possible saving of power be effected.

CAN'T NEGLECT POWER PROBLEM

The operator of a coal mine is interested in the total cost per ton above ground, and any comprehensive treatment must consider the power problem in its relation to all other factors which determine the total cost. Such subjects are reliability of equipment, capacity of machinery for hauling and hoisting, ample power distributing facilities, training of local electrical operators and maintenance men, selection and installation of new equipment, are all on a par in importance with purchasing power at a low rate.

There are four major power operations necessary in the production of coal from shaft mines, namely, coal cutting, haulage, hoisting and ventilation. Of these, the first two, cutting and hauling, are done electrically in practically all mines, while the change from steam to electric operation of hoists and fans has followed in mines with the advent of central station power.

In any mine the greater portion of the cost of mining is for work done underground, and this includes that portion of the electric system used for cutting and hauling. It is also true that here are met the most unfavorable operating conditions, requiring rugged equipment and constant supervision for the detection and elimination of electrical trouble. Falls of slate, bad track conditions, and continued extensions of lines due to development all contribute to make the problem a difficult one.

AT 4,500 FT. COMES TROUBLE

Coal cutting machines and haulage motors are operated farthest from the source of power when the generating unit is located at the shaft or at the surface. With direct-current operation voltage conditions usually become acute at distances in excess of 4,500 ft. unless a generous amount of copper has been used in the feeders and the track circuit is in unusually good condition.

Where alternating current is used, distribution voltages can be maintained by using step-down transformers and by moving them to new load centers as development requires. In small mines where haulage motors and cutting machines are operated from the same feeders, fed from direct-current gen-

erators located at the top of the hoisting shaft, the problem of maintaining voltage becomes more complicated.

Any man who is responsible for the purchase and use of electric power, and wants to do his work well, should fortify himself with the exceedingly useful and valuable information which can be obtained with a good set of graphic instruments.

The cost of mining coal can be reduced by thorough surveys and tests with the following purposes in view: *a*, Improving power supply by bettering distribution; *b*, eliminating unnecessary power losses; *c*, reducing maximum demand and raising power factor; *d*, reduction in time lost and repair costs due to breakdowns and failure of power supply; *e*, eliminating inefficient equipment.

PUT VOLTMETERS TO WORK

When the haulage motors are pulling on grades in mines where the cutting machines and haulage motors are operated from the same circuits, the voltage becomes so low as to stop the cutting machines altogether. Often graphic time-voltage surveys at the working faces show where a system of cross entry tie lines installed at proper places will improve conditions to such an extent as to make possible good operation of all equipment. In most direct-current underground systems, low voltage can be corrected at very little cost by the installation, where the bottom warrants, of cross lines and automatic circuit breakers and by properly bonding the return track circuit.

Graphic tests make it possible to determine the power consumed by each machine, and a comparison with previous tests or with tests of other machines of the same size and type, shows whether the machine is in normal operating condition.

By keeping charts of all tests filed and indexed, it is possible to accumulate a fund of information that is valuable in checking up trouble, laying out extensions and specifying new equipment. A report on operation, accompanied by records taken on the spot, leaves no room for argument.

A graphic wattmeter, as used for testing individual machines and measuring maximum demand, may also be used for checking up power consumed when the mine is idle, and thus determine the power wasted due to grounds and other leaks. The procedure is to connect the instrument into the circuit and take the load curve of power consumption during idle hours. Short peaks at intervals are usually caused by the occasional operation of a locomotive. The steady part of the load will be a combination of the loads due to small pumps, converters and lights, together with any leakage due to grounds, faults, etc.

Power cost per ton of coal mined, whether purchased or generated locally, is a small proportion of the total cost of production under normal operating conditions. However, it can become a large figure by causing partial or complete loss of tonnage through failure of power supply or equipment.

Service is, therefore, the first requisite all along the line, from the source of supply to the smallest motor, and it is necessary, probably more than in any

Fig. 3—Underground Transformers

Some transformer stations underground are almost if not quite as elaborate as any to be found on the surface. Carrying high tension current to load centers within the mine has done much to better the voltage on haulage systems.

other industry, that frequent electrical surveys be made and poor operating conditions improved before serious and costly delays result.

Surveys of load conditions, power factor, and voltage can only be accurately made with the use of graphic instruments. However, many things can be found by visual inspection, such as broken and hanging insulators, loose trolley wire allowing trolley pole to come in contact with slate, defective lightning arrester installation, accumulation of copper dust on generating machines, poor commutation, etc.

The following costs are for mines which purchase electric power for haulage, cutting, miscellaneous small motors and lighting, using steam-operated hoists and ventilating fans:

Tons produced in sixty days, eleven mines	515,519
Kilowatt-hours per ton	1.71
Electric power cost per ton	4.0 cents
Cost per kilowatt-hour	2.4 cents

The highest purchased power cost per ton occurs in mines having mixed power; that is, in mines where only a small per cent of the total power used is purchased. Such mines usually create a high maximum demand compared to energy consumption. This condition occurs when the development of the mine has caused a power consumption in excess of the local generator capacity, thus necessitating the purchase of power during working time, and, in many cases, because of inadequate supply of good water for boilers.

In a coal mine, poor running time and consequent high cost of production is generally due to one of four things: lack of orders, car shortage, labor trouble or failure of equipment. The operator has virtually no control over any of these conditions except the maintenance of his equipment, which makes it important to keep the mine in condi-

tion to operate efficiently when the first three conditions are favorable.

Mr. Harrod said that in no single month in the past three years have all the demand charts of the members of the Indiana Coal Operators' Power Association been absolutely correct. One or two of these charts has always been found wrong.

Graham Bright, in commenting on the remarks of Mr. Harrod, said that the average mine knew little about inspection. In earlier years steel mills and street-railway companies had less complete inspection than they have today. Now they spend twice as much on inspection as on repairs. They do this not so much to save repairs as to assure continuity of operation.

Speaking about bonds, Carl Lee said that he did not believe an over-all test of much value, for you may tell the operator that his return is bad but what is he going to do about it. The Peabody Coal Co. runs individual tests of every bond on main-line track and leaves a mark to show the repair man where the repair is needed. In this way good results have been obtained. The number of bad bonds varies. Some 2 to 15 per cent of all bonds are defective. The bonding gang may finish a section one day and the next day it may go back and find that track switches have been taken up and the bonding destroyed. Mr. Lee said: "We have found that tests made from rail to rail are more practical than any others and that the arc-welded bond is the best. Some have been in four years, and we have never found one defective due to imperfect welding."

J. H. Edwards remarked that he supposed the mines of which Mr. Lee was electrical engineer kept their bonds in perfect condition. In that case the tests from rail to rail were to be preferred. Individual bond tests were the ultimate criterion but he had found by experience that for the average mine with its low-grade bonding system the over-all bond test which gave the average condition of the whole mine was the more valuable. In consequence he had abandoned the bond tester.

TAKE OVER-ALL EFFICIENCY TEST

Periodically, or when conditions show that the bonding is deficient, an over-all bond test is made. In case of a converter, it is run with a reduced current and then what the Elkhorn-Piney Coal Co.'s electrical department terms, "a test for efficiency in bonding" is made. By repairing all bonds which were found on visual inspection to be defective, this department has found that the efficiency could be kept 90 per cent perfect.

In one case the general manager suspected something was wrong and notified the superintendent. The latter declared that he believed the bonding was good. Finally a test was made and it was found that the efficiency was only 60 per cent. The bonds were visually inspected and other tests were made and as a result the bonding efficiency was brought up to 95 per cent and the power costs were reduced proportionately.

Mr. Lee said that many of the bonds in the Peabody Coal Co.'s mines were so covered by fallen coal and slate as

to be invisible. He found the quickest way to examine them was with a bond tester rather than with a shovel. He presumed that Mr. Edwards referred to the fact that defective bonds will dry the rail at the joint. He wanted to know how he would detect such bonds where no current passed through the rail. Suppose between the cross bonds there are six joints in one line of rail and among them three or four bad bonds. They prevent the current flowing in that line of rail, and in consequence though they do not heat up they may be extremely defective.

Mr. Edwards remarked that he had used recently a pocket compass as a means of detecting the absence of current. This will show quickly whether one rail is carrying the whole electrical load and the other rail is dead. His experience in six mines in West Virginia and Kentucky, he said, did not include bonds that were invisible except those that were covered by dirt, mud and water. Little satisfaction was obtained with the individual bond tester. He had used the indicator type of tester, also the audible type with the

drill for contact. The latter, however, needed experienced men. He had also tried making a test at the joint but he found that it indicated a good bond when there was no bond whatever.

Mr. Bright said that at one of his mines it was the intention to have all the bonds tested. A crew was sent round and all the bonds were tightened. A high average of bad bonds was found. A good tight plate is essential to a good bond. In one mine a test was made of an average of 350 bonds for a distance of fourteen miles of track. After each 25 bonds examined a mark was placed. Every time a defective bond was found that was marked also. After the whole mine had been examined it was found that 61 per cent of the bonds were defective. After placing some 1,500 bonds a saving was made in the power bill of about 40 per cent. Now the regular bond man makes an inspection during every day that the mine operates. When the motorman sees a bad bond between numbers, say, 50 and 75 of the marking, he reports the fact to the bond man and it is repaired immediately.

Instruments that Decide Your Fortune

By J. F. MACWILLIAMS

Electrical Engineer, Pennsylvania Coal & Coke Corporation

IN THE concluding number of the Symposium "Problems of Electrical Men" J. F. MacWilliams, electrical engineer, Pennsylvania Coal & Coke Corporation, addressed the meeting on the importance of having instruments to test the operation of equipment so that knowledge may replace guesswork.

"With competition in the coal industry as keen as in any other field it behooves all engineers to effect every possible saving. First of all, this means that our engineering must be high-grade and that every piece of equipment must operate efficiently.

To obtain these results, nothing is so important as operating data. If our engineering service is to be paragon we must know how present equipment functions, whether it be efficient or inefficient; and if we are going to get the best results from the apparatus which we install we must be eternally vigilant and prompt to prevent or discover wastes.

The first thing we must do is see that the equipment we purchase is capable of doing its work efficiently. Next, we must make sure that the apparatus is properly installed and maintained so that it will be able to do its work effectively.

Unless some definite system is adopted for the testing and inspection, much time and effort and considerable valuable information will be lost. Our company has therefore decided upon and carried into effect a plan whereby every important piece of new equipment is tested before it is placed in service. This survey usually proves whether the equipment is suitable for the work, checks the performance curves, discloses its limitations, determines whether the installation has been satisfactory, and gives us an opportunity to plan better methods.

In our repair shops, we try to test all

repaired apparatus before returning it to the mines. Such a procedure quickly discloses short-circuits, reverse connection, grounds, etc. Our experience in this work has taught us much. When we first started our present method of testing we found that the number of defective field coils in service on electric motors was astonishing. These coils are of so low a resistance that a ten-degree difference of temperature will in many cases affect the usual testing apparatus more than two or three short-circuited turns of wire in the coil, and therefore make it almost impossible to arrive at any definite conclusion.

We believe the only way to test these fields is by a special transformer which we have designed and which is now being built by the Flood City Manufacturing Co. of Johnstown, Pa. This company is also building a bond tester which we have developed.

As we have increased the personnel of our testing department we have reduced our maintenance force. This, to us, is conclusive proof of the wisdom of such a course. As a result of our tests we have become convinced that the protection of motors by overload relays and fuses is unsatisfactory because they cannot give the proper delay. We have concluded, therefore, that if we could procure perfect thermal protection, we could take care of the motor under any condition. Excellent results have been attained by thermal relays for bearing protection, but disappointment has been the result of installing relays intended to protect the coils of alternating-current motors.

Consequently, we are considering the matter of designing a thermal motor protective device and hope to be able to have one for test in a short time. This device will be built on the principal of the Wheatstone Bridge, the galvanometer being replaced by the trip element, a relay now quite common. Two of the branches of the bridge will be made into a rope placed around the coils.

In the field we must first of all ascertain whether the electric motors are re-

ceiving the voltage for which they are designed. If the pressure is low, we are losing not only the cost of the wasted power but also the cost of the excessive labor required to keep the machine in repair. Then again, there is a serious loss due to the fact that the machine does not earn enough to pay for the investment in it.

At each important mine, we have placed Bristol graphic recording voltmeters which are moved around to the different distribution centers, thus keeping a constant check on voltage conditions. If low voltage is found at any center, an inspection is made, and if the trouble is not located at once, tests are made of the feeders and bonds. The man making the test makes the repair again and tests the circuit. Once a year a general test is made of all feeders and returns by connecting overhead conductors and return circuits solidly together at distribution centers and applying sufficient voltage at the substation to produce the average current required. Thus we determine power loss. We have found that though the Bristol meter may not be as accurate as others, still it will indicate the variation in voltage.

Pumping and ventilating require a great amount of power and if a careful check is not made, efficiencies as low as 30 per cent are common and may be allowed to continue. Pressure and vacuum gages give very good indications of the performance of centrifugal pumps and an ammeter in the motor circuit will check the operation of the motor. Upon a pump or fan giving any sign of trouble, a test should be made to determine the cause. A careful test of every important fan or pump should also be made immediately after its installation. The power input to the motor the discharge as well as pressure readings should be taken.

DON'T OMIT TESTING THE FAN

Fans should be tested under various conditions of speed, pressures and capacity by corrected anemometer or pitot tubes, water gages and thermometers. We make a practice of dividing the section of the airway, where anemometer or pitot tube readings are taken, into not less than 12 parts and use a water gage arranged for various angles of inclination to obtain accurate readings.

For testing locomotives and determining the tractive effort required to haul cars equipped with different kinds of bearings, we use oil dynamometers. In making tests of bearings, a full trip is hauled over a heading having markers established to indicate changes in grade and distance. Drawbar pull multiplied by miles per hour is checked against kilowatt input. The weight of the trip is carefully taken, and the observation car with contents is run over the route at the same speed as the trip. In this way, we are able to determine the power required by the locomotive and observation car."

In discussing Mr. MacWilliams' paper, Mr. Webster said he had designed a bond tester for low current with three rigid sides and one that is hinged and rests on a leg. When a short-circuit is found the tester immediately gives a reading. It is easy for a man to throw in the coil and close the switch.

How to Clean and Size Coal So That a Favorable Market Can Be Maintained

By Air Cleaning, Ash Is Reduced Between 33 and 50 per Cent—Coal Gets to Market Unfrozen—What Coal Should Be Sized in the Tipple and What in a Rescreen

Winnowing Coal to Separate Its Impurities

GETTING dry coal that will not freeze in winter, saving much of the clean coal that is lost in wet-washing processes, running the plant in winter without trouble from frost and obtaining refuse running from 82 to 87 per cent were among the achievements recorded by Humphrey D. Smith, general superintendent, American Coal Co. of Allegany County, with mines around the Bluefield district of West Virginia, at a meeting on coal preparation at the American Mining Congress, May 13.

Mr. Smith said that at the plant of the Crane Creek mine, the 185 tons per hour that goes through the 2-in. circular openings on the horizontal shaking screen is carried to the top of the dry-cleaning building, and thence is passed over screens, through bins and over tables to the storage bins alongside the railroad. At the plant of the Wyoming Coal Co. approximately 150 tons are treated per hour. To return to the Crane Creek plant, this is provided with a battery of 36 Hummer screens, and this divides the coal in seven sizes; 2 to 1½ in., 1½ to 1 in., 1 to ¾ in., ¾ to ½ in., ½ to ¼ in., ¼ to ⅛ in., and ⅛ in. to dust. The coal from ⅛ in. to dust is bypassed and not treated, but the other sizes from 2 in. down are passed through the cleaning process.

STORE COAL OVER AIR TABLES

The coal that passes through the vibrating screen falls into bins of 15 tons capacity, one being placed over each separating table. The bypass coal under ⅛ in. is chuted directly under the floor of the table room. The coal from the bins just mentioned is fed by reciprocating units to the feeding ends of the cleaning tables. It has been found that it is extremely important to keep a constant bed of coal on the

table. The provision of 15-ton bins is valuable as a means of steadying the flow of coal to the tables. The Crane Creek plant has been in use approximately a year and has handled 192,000 tons of coal, running from 2 in. down to dust.

In treating the coal the American Coal Co. has found that on the larger sizes it has not been possible to get enough of the coal to properly bed the table. Consequently, it has been obliged to run the larger sizes, those between 2 and 1½ in. and between 1½ and 1 in., intermittently, using the 15-ton bins in which to store the coal until enough has been gathered for the running of the table. The general average of all tests taken indicates that the percentage of ash in the crude coal averages about 10 to 12 per cent. The average ash in the clean coal as shipped in the railroad cars runs approximately between 7 and 8½ per cent, although some samples run better and some worse.

ASH CUT IN TWO OR CUT A THIRD

Coal that is shipped includes the bypass coal which is not treated on the tables. The coal actually treated by the dry-cleaning process will run from 4½ to 5 per cent ash up to about 6½ to 7½ per cent. The large-size crude coal runs from 13 to 17 per cent ash, and the small-size coal usually between 9 and 10 per cent, thus it is evident that the ash reduction varies between 33½ per cent and 50 per cent. In the operation of the plant we use three fans. One double 72-in. fan which handles the air from the first two largest sized tables which prepare coal running from 2 to 1½ in. and from 1½ to 1 in. The other half of the double fan handles from 1 in. to ¾ in. and the third fan handles all sizes from ¾ in. down to ⅛ in.

The Crane Creek plant has eight tables in operation. About 100,000

cu.ft. of air per minute is handled through the dust-collecting system. The air for the fans comes from large hatches and passes into two large centrifugal dust collectors placed on the outside of the building.

The American Coal Co. is recovering all the dust except the very finest air float, which would be under 200-mesh. The dust from these collectors is piped, taken over to the clean-coal elevator, where it is remixed with the clean coal in the same proportion as it was taken out. Bypass coal also is added in a similar manner.

The present plant being built into an old wet washer has some six or eight operations that would not be necessary if a new building had been erected. In consequence the power consumption is slightly in excess of what would be good practice. Taking the connected load in the plant as approximately 525 horsepower the consumption of power per ton of coal treated would run 2.35 kw.-hr. Some reductions in that consumption are anticipated as a result of changes made in drives. The officials hope in time to be able to handle a ton of coal with a power consumption of 2 kw.-hr.

ABOUT FOUR MEN IN PLANT

In the plant four men are employed and occasionally five. Since the beginning of the year the number of men employed in the building has averaged 4½. In estimating the cost of cleaning this coal a charge for depreciation has been added, and this has been made large because the structure is of wood and may have to be replaced before many years. In round figures the cost of dry cleaning coal at this plant is about 20c. per ton including labor, power charge and plant depreciation. No charge has been added for the loss of rejects, which some might think should be included.

All the coal is sold on the market

Fig. 1—Lump Screens in a Tippel

Thorough screening is a primary requisite of coal preparation. Oscillating screens have almost entirely supplanted those of other types. The perforated plate has also almost completely taken the place of woven wire as a screening medium.

and the loss of this rejected matter reduces of course the product that is available for sale. One of the main advantages of dry-cleaned coal is that it does not freeze in the winter as does the coal from the other cleaning plants of the American Coal Co. which use the wet process. Another advantage in dry cleaning is that the loss of fine coal is at a minimum. The ash in the refuse will average from 82 to 87 per cent, which shows that only a small quantity of coal is wasted in the washery.

REFUSE AT CRANE CREEK HEAVY

The refuse has about twice the specific gravity of the coal, and that makes the cleaning problem more or less easy. Another advantage of this process is that as it is dry it is possible to operate the plant when the temperature is below freezing as well as in warm weather. In fact the cold air makes the tables operate more successfully in winter than in summer.

Replying to G. A. Vissac, general manager of the West Canadian Collieries, Ltd., of Blairmore, Alta., Canada, he said that the larger sized screens were extremely effective, because such a small tonnage goes over them. The smaller sizes gave practically no trouble above $\frac{1}{8}$ in., the screening efficiency varying with the moisture obtained in the coal. Sometimes wet trips that will carry 4 to 8 per cent moisture will come out of the mine and this coal cannot be screened down to $\frac{1}{8}$ in. In that event fine screens block up and it is necessary to bypass some of the finer coal.

In reply to M. B. Morrow, Canmore Coal Co., of Canmore, Alta., Canada, Mr. Smith said that the dry-cleaning plant is equally efficient with coal from 1 in. to 2 in. as it is with smaller coal, but it is absolutely necessary to have enough of any one size to bed the table properly.

The chairman of the meeting, Colonel Warren R. Roberts, declared that these tables at the Crane Creek mine would handle 240 tons an hour and Mr. Smith

said that he believed the plant could be run at that capacity and give efficient service. The tonnage produced in the past year, namely 192,000 tons, passed through the plant in 170 working days of eight hours.

L. E. Woods, president, American Coal Cleaning Corporation, said that there were two pneumatic coal-cleaning plants in West Virginia, a small one in the far West, one in New Mexico, two tables at Niagara Falls cleaning coke and four tables soon will be working in England. All told there are more than thirty tables in operation with an annual capacity of a million tons.

R. W. Arms, of the Roberts & Schaeffer Co., said that air cleaning required more careful sizing than water. Nevertheless it is not absolutely necessary to provide for eight or ten sizes at every cleaning plant. It has been shown that it is possible to select one extremely dirty size and by cleaning that size alone to make an effective reduction in the ash content of the coal. The cleaning of coal involves a shrinkage in the quantity of coal delivered to the market. Each operator should select for himself what shrinkage he is willing to effect in cleaning his coal. He must drive out the dirt with air or wash it away till he strikes a happy medium.

DOES NOT PAY TO OVERCLEAN

Coal men had explained to him that the public does not really want an extremely low-ash coal and that if the ash in coal could be reduced till only the inherent ash were left, the coal would not be a good fuel under ordinary conditions as they now exist. Whether or not that is true is a matter for each man to decide, but it is certain that a product having a uniform percentage of ash is more to be desired than one that has an extremely low but variable percentage. It is found that the air-cleaning system produces a uniform ash, which really is a tangible asset.

E. W. Park of the Interstate Coal Operators' Association, desired to know if the same blast of air is used for all

the seven different sizes in the Crane Creek installation. Mr. Smith said that each table has its own air pressure. The blast with the larger size of coal is heavier than that with the smaller sizes. It is heavier for the 1 to $1\frac{1}{2}$ in. than for the coal larger than $\frac{1}{8}$ in. and under $\frac{1}{2}$ in. The four tables which clean the larger sizes take twice as much air as the tables which clean the smaller sizes. After the air is once adjusted to get the needed suspension the air delivery need not be changed for a month or even months at a time.

Mr. Smith in answer to Mr. Woods said that he did not believe that \$15 had been spent on repairs since the tables had been installed. There is nothing to get out of order. A motor bearing on one of the tables heated and it had to be rebabbitted and one of the original decks that came with the tables is still in use. A small hole about 1 in. square had to be repaired where the refuse left the table by which the largest size was cleaned.

However, the air delivered to the tables should be as clean as can be obtained. Otherwise the small perforations will clog, and the decks will have to be removed so that they can be cleaned from the underside. At the Crane Creek plant the air is obtained from intake pipes running perhaps 50 ft. beyond the building. These pipes are 36 in. in diameter. In this manner clean air is provided.

George Delamater, of the W. S. Tyler Co., said that an 8x5-ft. screen would handle 100 to 120 tons per hour when screening $\frac{1}{8}$ -in. coal. An 8x5-ft. screen requires 1 hp. to operate. A $\frac{3}{4}$ -in. screen with 20-sq.ft. of screen surface will need one horsepower to drive it and will handle 180 tons an hour. Wet coal can be screened satisfactorily down to $\frac{1}{8}$ -in. Below that it will give some trouble. In every instance the vibrator must be given enough vibration to handle the maximum load.

How Should Coal Be Screened And Into How Many Sizes?

Salesmen too often take contracts which compel a reconstruction of the tippel, causing not only much unprofitable expenditure but destroying the whole design to such an extent that the coal is prepared and loaded with excessive degradation, said G. F. Osler, general manager of the Pittsburgh Terminal Coal Co., in the second half of the session on coal preparation in the afternoon of May 13. Hugh Shirkie, president, Shirkie Coal Co., was not present to discuss the relative claims of preparation in the tippel and preparation by secondary equipment in a separate structure.

In Pennsylvania, said Mr. Osler, picking tables did not become general till the year 1917. In the Pittsburgh district only four sizes are being made—slack, nut, stove or egg and lump coal. For this reason Mr. Osler did not consider a Pennsylvania operator competent to judge whether an Illinois producer should do all his sizing under one roof or erect a secondary building in which to do the rest of the work nor where a line should be drawn between the two.

Scenes at the Crane Creek Mines, American Coal Co. of Allegany County, McComas, W. Va.

Fig. 1—Tippie and dry-cleaning plant. Tippie, boom house and dump in front, dry-cleaning plant in rear. A large inclined elevator takes raw coal under 1-in. diameter up to cleaning plant from tippie. Fig. 2—Rear view of dry-cleaning plant. Note the five-track yard for mine cars feeding to dump house, the two large dust collectors and fans taking dust from the screens and cleaning tables. Fig. 3—Vibrating screens set in two batteries. View shows three 8-ft. screens having two vibrators for each screen. The plant has twenty screen units with thirty-six vibrating sections. Coal passing over and through these screens goes in bins over the cleaning table floor.

Fig. 4—Cleaning table floor with eight tables. Starting at front, first table at right treats 1½- to 2-in. coal, first table at left 1- to 1½-in. coal, second table to right ¾- to 1-in. coal; second table to left ¾- to 1-in. coal, third table, right and left, ¾- to 1-in. coal, fourth table, right and left, ¾- to 1-in. coal. Big hoods over each table with large air pipes take air and dust off tables to fans located outside the building. The discharge from the tables includes three separate products—clean coal, middlings which are run over the tables a second time and refuse. Chutes take this refuse to conveyors under the table floor. Fig. 5—Rear of cleaning table showing

fresh-air intake pipe to fan built in table. The valve permits the intake pipe to be closed thus allowing the attendant to control the quantity of air supplied to the table deck. Note that the eccentric drive for oscillating the deck of the table has cone pulleys for varying the number of strokes per minute. Fig. 6—Back view of cleaning table showing discharge from table deck. Movable flights allow changing cut between clean coal, middlings and refuse. Note the hood for the dust collector above the table. The chute above the table leading from the steel bin makes it possible to bypass coal whenever a table needs repairs, thus enabling plant to run.

In his view the principal need was to handle the coal as few times as possible, for every time it was handled the coal suffered from degradation. "The salesman and customer," said Mr. Osler, "are against the operator because the salesman will promise the customer almost anything he asks. He often asks us for a separation of sizes for which we are not equipped." The engineer in designing the tipples builds it to satisfy the requirements of the operator as

weigh basket without degradation. Some of the coal is passed over shaking screens but some still is sized on gravity screens, though that is regarded today as antiquated practice. Most of the operators, engineers and tipples builders do not seem to realize that mine-run coal will break. Where shaker screens are used, the shape of the screens determines in large degree how much slack they will make and how much slack they will remove.

Fig. 2—Interior of a Bituminous Tipples

At many mines four sizes of coal are prepared. Two and sometimes three of these are hand picked on travelling apron or pan conveyors. The two larger sizes also are usually lowered carefully into railroad cars by means of either loading booms such as that here shown or by shaking chutes. Either of these devices may be lifted clear of the car when not in use loading coal.

they have been detailed to him. No sooner is the structure completed—even before it is completed—than the operator finds he wants "to do some stunt with the coal."

The salesman has been busy trying to get the operator to accept a contract having a freak specification. The operator has assented and has cavalierly remarked "We'll fix that. Our engineers will work it out." They do—by dropping the coal some 7 or 8 feet. If operators would take a moment to consider the breakage of coal after screening they would not ask the engineers to handle the coal in so many ways without the use of conveyors. The tendency is to make the primary screening of the coal the only operation.

Coal should always be slidden and not dropped. All chutes should be covered from the screens to the point where they discharge into the car, as the quantity of dust which is blown from the chutes is worthy of consideration. Around a tipples where the chute is not covered by a housing, slack can be found covering everything with a thick coat. The immense quantity of dust in the air is far from healthful for the men working on the picking tables.

In the Pittsburgh district little attention is paid to getting coal into the

In a recent investigation Mr. Osler found that of the nine tipples of the Pittsburgh Terminal Coal Co. equipped with shaking screens, hardly two screens, though they were all of the same type, would screen the coal alike. Wet coal would stick to nearly every type of screen. The best screening medium for wet coal was a screen having a step 6 in. long with a 2 in. rise and not a long sloping screen. He found that the 12-in. steps would become wedged with small pieces of coal and that the wet coal would ride over them. He also found that some of the screens had been so arranged that the coal became worn in passing over them, thus increasing the percentage of slack.

Warren R. Roberts, the chairman, said that in Illinois, where seven sizes of coal are made and the operator desires to put in only a four-track tipples, it is necessary to erect a resizing plant to handle those sizes that cannot be separated in the tipples. This question presents itself: What sizes should be handled in the rescreen plant and which on the main screens? Some plants have been designed so that only the lump and egg were loaded directly under the tipples. No coal should be rehandled that can be sized in the main building.

Frank E. Young, of New Mexico, said that in that state five sizes were made

at the tipples, but he thought that if a sixth size were made it should be taken out by a different separation. The smallest size prepared (1½-in. to ¾-in.) is made at the tipples and is loaded out there. The lump, egg and nut are loaded by booms but the pea coal, which is 1½ in. to ¾ in., is loaded out by a curved chute crosswise of the car. Mr. Young said that lump coal sold for \$4, No. 1 nut and egg for about \$3.25, pea coal for \$2.75 and slack for \$2.25, so there was large saving wherever coal was not degraded.

Mr. Roberts said that Illinois was preparing altogether too many sizes of coal and that he had always endeavored to oppose the installation of machinery for such excessive preparation. He agreed with Mr. Osler that the distant salesman often reported that he had sold a quality of coal that the plant was not designed to deliver and that the engineer was asked to redesign a plant which had been working successfully. This rearrangement ruined the tipples as far as the handling of the coal over the primary screens was concerned. If a company has a plant that satisfies 95 per cent of the orders, it should not be ruined to please the other 5 per cent. The operator should let some other fellow cater to that small percentage. Suppose seven or eight sizes are made and there is a market for only five or six, what is going to be done with the other two? It would be well for operators to reduce the number of standard sizes.

Mr. Tracy remarked that on Jan. 26 in a certain district of Illinois of unbilled cars there were eight of lump, nineteen of egg, forty-six of nut and 192 of slack. The operator is certainly in difficulties when he has only eight cars of lump left to 192 cars of slack. How can he operate profitably, manufacturing such a large quantity of distress coal?

Mr. Smith said that at some portions of the year conditions would be reversed. The demand for sizes was changing owing to the installation of different kinds of boilers. For a while the old-fashioned boilers that could not burn the finer sizes were still in use, but of late years as these boilers played out they were replaced by others that had grates that could burn the finest sizes. Furthermore, all the entirely new installations were of that character. The tendency was toward buying finer sizes of coal.

Industrial Co-operation Lunch

On Thursday, May 15, the American Mining Congress canvassed the subject "Industrial Co-operation" with Harry N. Taylor, president, U. S. Distributing Corporation and Sheridan-Wyoming Coal Co., presiding, and F. W. Smith, F. P. Wright, Lee Lang and Carl Scholz as speakers. The latter showed a cube of oak wood, a cube of coal and a stick of gum, all of which sold for a cent. The cube of oak measured 2½ in. each way, that of coal 6½ in. The coal weighed over 10 lb. and had locked up in it the power of producing 174,000 B.t.u. Mr. Scholz remarked that no wonder the Wrigley Building based on the gum industry was one of the finest in Chicago.

Congress Wants to Do What Is Right But Is Looking for Counsel

Callbreath, Brydon, Parker, Gandy and Moorshead Discuss Present Position of Coal Industry—Congress Not Wrongly Purposed but Often Ill Advised

THE "Get-together" dinner on the second night of the Congress and the night before the National Coal Association began its convention was something more than fried chicken and a succession of funny stories and high-sounding but hollow phrases about co-operation. Some earnest words were spoken in an effort to convince the whole coal industry that there is real necessity for it to get together.

It must get together to combat the rising tide of socialism that is leading toward too much government control over business, J. F. Callbreath, secretary of the Congress, declared. He warned, after his long experience in Washington, that the pressure for legislative supremacy over the judicial is powerful and that real effort must be exerted to stop it.

As for Congress, whose action with regard to coal has long been viewed with alarm by the coal man, he declared that although our national legislative body has been strongly condemned from many sources, yet it is truly representative of the best thought of the nation and that many of its mistakes have been due to inability to get the right viewpoint on the matter in hand. It only needs to have a just cause properly presented in order to do the right thing, Mr. Callbreath thinks.

It is the right thing for the coal industry to adopt an attitude of "sensible selfishness," he said, and to campaign for the things to which it is justly entitled that it may exercise the great American privilege of working out its own destiny. If it gets that, it will prosper and the public will benefit.

The way for the industry to get together and pull itself out of the muck is not by legislation nor yet by consolidation of finances or salesmanship, said J. C. Brydon, president of the National Coal Association, but by a consolidation of thought and effort.

DAY OF SHARP PRACTICE ENDS

"The time has passed," he said, "when sharp practice or mere shrewdness will win any man permanent advantage over the rest of the industry. The most we can hope for now is to raise the general average benefit and enable it to flow to all."

He took the customary crack at the work of the U. S. Coal Commission, inviting anyone to point out a single commission remedy for the ills of coal. He said that the National has been making some use of part of the great mass of information gathered during the time of the commission's life, however, and that some benefit is being derived therefrom. It has aided the National in its successful efforts at Washington to prevent the passage of a mass of foolish legislation.

The battle of prevention goes on day by day against both friends and enemies, he said, reciting his experience with a friend¹ Senator to illus-

trate the point. He dissuaded this Senator from introducing a coal bill even though the Senator honestly wanted to benefit the industry.

"If that's what you want," said Mr. Brydon, "then don't propose it. The best thing for the industry is to be let alone. Whenever it has had the opportunity to operate unhampered it has furnished the public coal when and where it was needed and at a price lower than that of the product of any other industry."

"But," said the Senator, "if something like this isn't passed, the bolsheviks will pass something worse."

"Then let them pass it," replied Brydon. "If they have that much strength, then your bill, even if enacted, wouldn't last long on the statute books. The thought of this country is revolving in such swift cycles nowadays that if bolshevik coal legislation becomes law it will wear itself out in four or five years anyhow, and we will be through with it. So the best thing to do is withhold your bill."

It was withheld.

Mr. Brydon was optimistic about coal even though the industry is at a low point. The fact that Cincinnati had drawn together the greatest assemblage of coal men the industry had ever marshalled in one place at one time made

him think that "in spite of our condition, the spirit to do is with us."

E. W. Parker, director of the Anthracite Bureau of Information, humorously met Mr. Brydon's challenge to "point out a single commission remedy." He said that the commission plainly recommended on one page that the bituminous-coal industry eliminate brutal competition as the anthracite industry had done, and on another page, recommended that the anthracite industry go back to it again. In serious vein, Mr. Parker said that the coal industry must educate the people, difficult though that task seems. The anthracite industry is getting real results in its present campaign to show the public how to burn hard coal more economically.

The sound message of Harry L. Gandy, secretary of the National, was this: Coal problems will certainly be solved in the coming years. They will not be solved by legislation or by the appearance of some Moses of coal but in the everyday life of the men in the mines and the men in the business offices of the industry. His message was heard by an audience that listened to every word and applauded him heartily.

A. J. Moorshead, veteran Illinois operator and president of the Madison Coal Corporation, made an appeal for stronger organization among operators even in regions where conditions seem widely variant. In such cases, as in his own state, he urged that at least the officers of all the groups be associated so that the producing regions of the country could be bound into as strong associations as possible.

How to Get Lump Coal in Place of Slack

Adams Tries Union Co-operation and Instruction—Allais Wants Miner Paid on Similar Basis to Operator—Hatfield Relates a Return to Lump Scale and 6 per Cent Reduction of Screenings

AT THE close of the dinner on Tuesday a session was held to discuss the methods of blasting coal which would afford the largest percentage of lump coal. N. S. Greensfelder, presiding, read a paper written by H. C. Adams, of Chicago, president of the Peerless Coal Co., operating in the Springfield district of Illinois. At the Congress a year ago Mr. Adams led discussions on this same problem, and since then has attempted to carry out some of the ideas that he formulated at that meeting.

The Adams paper described the campaign of education that has been carried on by the Peerless company to get shotfirers to do their work properly. It has been productive of only meager results but still enough to convince Mr. Adams that such an effort is well worth while. It will be carried further.

He first sounded out the union labor officials and found that they were willing to back him up in enforcing that clause in the labor contract requiring the men to shoot the coal in such a way as to produce the lowest proportion of screenings. Then he chose some of his best men to instruct the others, and attempted to follow it up. A few miners were discharged for failure to

Not All the Slack Is Mine Made

Long conveyors often add to degradation. The handling at the tippie, however, frequently without conveyors, is far more harmful than any such transportation. The work of eliminating slack should start at the face and be followed painstakingly to the railroad car—a trip any superintendent might make with advantage, visualizing on the way the tribulations of a lump of coal.

Car of Straight Creek Coal from Bell County, Kentucky

This product is evidently screened coal. There is no really large coal among it but what of that? Large lumps have to be broken to smaller size by the consumer and he thus gets slack which he has paid for as lump.

co-operate. But on the whole the benefit was only temporary.

The overshooting of coal, he thinks, is the operators' fault for previous failure to enforce the contract and to give miners proper instruction. Education is the only way out. He blames solid-shooting operators for not making careful studies of their coal structure so as to determine best shooting methods.

Some concentrated effort in the East is being made to improve shooting methods. It was described by J. E. Crawshaw and C. W. Nelson, of the Bureau of Mines. Exhaustive experiments were made at the Naomi mine of the Hillman Coal & Coke Co. all winter as a co-operative effort between the Carnegie Institute of Technology, the Bureau and the Hillman company. It was shown conclusively that the percentage of lump passing over 1½-in. bar screens in that seam could be raised as much as 7½ per cent and powder consumption reduced 30 per cent. The tests will be described fully in *Coal Age*.

In the discussion of blasting that followed, A. L. Allais, president of the Columbus Mining Co., operating in Indiana and Kentucky, said that while education of miners of course would help a little, it still would be human nature for them to shoot coal down in the way that would reduce their own labor most, and therefore something further is necessary. He believes scales of pay should be changed so that lump shall be loaded out at one rate and screenings at a lower rate.

"That," said he, "is precisely the way the public pays the operator. What is good for the operator ought to be good for the miner."

J. S. Hatfield, of Cincinnati, interested his hearers by telling of a mine

in a non-union field that had actually gone back to a straight lump basis of pay a short time ago. The result at once was that 1½-in. screenings dropped from 40 to 34 per cent.

Shooting for machine loading was discussed briefly by W. J. Whaley, of the Myers-Whaley Co., of Knoxville, Tenn. For machine loading the whole face should be shot down at once so as

Pocahontas Coal on Deck of Ship at Lambert's Point Pier

This coal, like most low-volatile fuel, is friable though not as much so as is other low-volatile coal. As it is used for stokers its fineness is no fault. However there is plenty of larger-size material should it be desired to use it as a substitute for anthracite.

to give the machine as few movements from place to place as possible. Of course, this means a disadvantage as compared to hand-loaded mines where one end of the face can be shot down first and loaded out, leaving an open end which reduces the percentage of screenings for the next shot. To overcome this, he suggested the use of an air snubbing wedge with which the snub cut could be made without making much "bug dust." He proposed that the machine loader mine be organized so that all drilling and snubbing be done by two men working ahead of each machine. It always pays, he said, to delegate such work to a specified pair of men so that they may be held responsible for it.

Gas Proves to Be an Active Rival of Anthracite

By W. M. CARPENTER

Engineer, Empire State Gas & Electric Association

Anthracite is steadily increasing in price and at the same time declining in quality. Following long years of steady prices, where domestic coal continuously sold around \$5 at the New York harbor piers and the average price at the mines was under \$4 a ton, the upward climb began in 1916 at an average increase of 18 per cent each year, so that now the price of domestic coal stands above \$9 at the mines and retails at New York in the neighborhood of \$15.

SHOWS LARGE RATE OF INCREASE

Of all the multitude of articles listed by the U. S. Department of Labor no other commodity in this country has shown such a continuous and extravagant rate of increase as have domestic sizes of anthracite, and the end is not yet apparent. Coincident with these strides in the cost of hard coal a similar increase has been manifested in the use of manufactured gas for heating. The curves of the retail price of anthracite and the domestic consumption of gas show a parallel which is little short of uncanny.

In 1910 the per capita use of anthracite in New York State was 1.75 tons a year and the consumption of gas 6,500 cu.ft. In 1923 there was a 94 per cent rise in the price of coal over 1910 and a 95 per cent increase in the use of gas. The annual per capita use of anthracite has now dropped below 1.50 tons where gas consumption per capita has risen to over 10,000 cu.ft. It has been estimated that the 75c. added to the retail price of hard coal because of the "settlement" of last September's strike will automatically sell—without any effort whatsoever on the part of the gas companies—over 7½ billion cu.ft. of manufactured gas in New York State alone.

Abstract of address delivered at the Binghamton meeting, the Empire State Gas & Electric Association.

What the Mechanical Loader Can Do and How It Has Been Brought to Its Present Perfection

Loading Machine No Longer Experimental—All Machines Succeed Only in a Mine Slightly Changed to Accommodate Them—Record of Pocahontas Fuel Co.—Dangers of a Premature Scale—Sizing and Cleaning Problems

Record of Advance in Mechanical Loading

"COAL companies," said Howard N. Eavenson, chairman of the meeting to discuss "Correlation of Mechanical Loading with Haulage and Mining Systems," "seem to think that the inventor of loading machines should develop equipment that would step into the coal mines and do its work without making any change whatever in the methods and organization hitherto in use." Mr. Eavenson estimated that there were about twenty different kinds of loading machines that had been used at some time or other and which had reached various stages of development. Three, at least, of these have been used on a commercial scale.

Mr. Eavenson recalled how difficult it was to introduce the electric locomotive. The roads were built for mule haulage, and operators thought the electric locomotive should be able to use the same weight of rails, the same size ties, the same roadbed, and roadways as crooked as were customary with mule haulage. But in this they soon were disappointed. The new transportation machine had first to revolutionize tracks and roadways. He said that in his opinion the loading machine was about as well-developed as was the shortwall undercutter some twelve or fifteen years ago. The mechanical loader was ready to do its work, but the mine had not yet been adapted to its operation.

D. J. Carroll, chief engineer, Chicago, Wilmington & Franklin Coal Co., said that the history of coal-loading ma-

chines dates back to about 1905, when Mr. Hamilton of Columbus, Ohio brought out the first elevator conveyor type of loader. At that time J. Elwood Jones was working on a loader which is still operating.

In 1908, the Myers-Whaley Co. introduced its machine which loaded out coal successfully. The coal-mining fraternity was not at that time ready for a loader; a contractor wanted to muck tunnel rock and observing the loader in operation, he introduced it into the contracting business. Since then these loaders have been used extensively in connection with big tunnel work.

In 1912 the Jeffrey Manufacturing Co. brought out the entry-driving machine. Its first application, as far as Mr. Carroll knew, was in Old Ben No. 9 Mine in the southern Illinois field. It operated there only a month, and owing to mechanical defects it was not altogether successful. In 1918 it was used in Valier, Ill. and was found quite satisfactory, but had to be abandoned owing to trouble with the Union. No satisfactory rate could be obtained for its operation. Carl Scholz used the machine later in West Virginia with more success.

In 1920 the Chicago, Wilmington & Franklin Coal Co. bought a Joy shovel but held it a year till Orient No. 2 came into service, fear of labor difficulties making it advisable not to introduce it in Orient No. 1. Several more Joy machines and three Myers-Whaley shovels were purchased later, and they have been in operation loading each day 1,200 tons of entry coal in eight hours.

The records of the company are not

as yet satisfactory, for the machines cannot be worked more than 50 per cent of the time owing to switching delays, lack of track facilities and time lost waiting for shots. Nine Joy and four Myers-Whaley loaders are now in operation. Though the machines have not exhibited how much they can load, they have been extremely valuable, for with them 100 per cent more entry has been driven than could have been done with hand loading.

In response to W. L. Robinson of Cleveland, Ohio, Mr. Carroll said that no labor scale had been established. The scale in Illinois is based on the rate paid in 1913 when the Jeffrey entry-driving machine was introduced into the Old Ben Mine, which is \$8.54 a day. The rate is being discussed with the United Mine Workers and it is expected that a scale ultimately will be fixed. No tonnage rate has been set. All men operating the machines are paid by the day.

J. F. Joy, on being interrogated, said that there were 200 Joy loaders in use, 16 in Illinois, 30 in Indiana, 20 to 25 in west Kentucky and the rest located in the prairie country. None are in Tennessee or Alabama, but they are working in the Rocky Mountain Coal Fields, in Pennsylvania, western Kentucky and Ohio. Mr. Whaley said that the Myers-Whaley company had about 40 machines in the coal mines. Asked as to the saving effected by the operation of his machines, Mr. Joy said that the only knowledge he had was from an operator in West Virginia who claimed that he could load with his Joy

Fig. 3—A Large Shovel at Work

Shoveling machines will do much to increase the size of mine cars as it takes no longer to shift a big car than a small one. Best work will be done by a mining machine when a whole trip can be loaded without uncoupling a car of the locomotive. Room and pillar mines may be so laid out as to accomplish this result. This permits the machine to work a large percentage of the time and secures large output from a small area.

loader at about 30c. per ton less than by hand loading. This was based, he believed, on the 1920 wage scale.

W. J. German said that the Pocahontas Fuel Co. had 23 coal-loading machines and last year loaded 998,000 tons by machine. At Big Branch the company has three machines which among them loaded 1,100 tons every day. It is having less trouble with its loading machines than with its main-line and gathering locomotives, which speaks well for the construction of the machines. The company's figures show they have less accidents per 1,000 tons loaded by machines than they have with hand loading. At the mine mentioned there are no miners, all the work being done by machine.

For the last two months they have had machines at work that are only 44 in. above the rail. The mine is run by room-and-pillar, one car being loaded at a time. The machine used is the "Coloder," made by the Coloder Manufacturing Co., Columbus, Ohio. The only coal company using them is the Pocahontas Fuel Co. It mines the Pocahontas No. 3 seam which runs at this plant from 6 to 7 ft. thick and has the usual parting which has to be removed.

Drawslate Does Not Prohibit

There is also a drawslate running from 3 to 10 in. thick. This has to be brought down and removed before the machine begins to load. Fortunately it is not found everywhere in these workings. In most places it comes down with the coal when shot. Success has been obtained largely because the company is determined to make the machines successful. Mr. German added: "The company must be sold on the idea before the machine will be a success."

R. A. Walter, consulting engineer of New York City, said that a series of observations on these machines showed a daily average of 585 tons for one machine, the test extending over several months. Mr. German added that Mr.

Jones had said to him that anyone who wanted one of his machines could have it by paying for it. The company has been working for fifteen years developing this machine and they believe it is still far from its ultimate development. They are building now solely for their own use, but anyone who wants one can purchase it.

Only One Man Has Been Injured

Mr. Eavenson said that he had been informed that up to about a year ago only one man had been injured when at work at the machines since they had been installed. He added that the company had been getting more and better coal from the pillars with the machines than by hand. They were able to do this because they excavated the coal more rapidly than could be done by manual methods. This, Mr. Eavenson believed, was true of all machine loading because a machine can do in an hour as much as two men in a whole shift. In consequence when in a dangerous place the coal can be withdrawn so fast that the roof breaks where it does not endanger the men and timbering does not have to be done so frequently.

Mr. Smith, of the Illinois Coal Corporation, indorsed Mr. German's insistence on the importance of having the coal company back of the machine. He hoped, however, that in their anxiety to get the mechanical loaders working satisfactorily, the officials of the coal companies would not make unfavorable working conditions that could not be broken throughout the life of the industry. Years ago the meager performances of the earlier mining machines set the rate for those which followed. The shortwall undercutter has been introduced since then and so have arcwall machines. However, they have never achieved as much for the industry as they might have done, for their production has been restricted to the performance of the earlier breast machine.

Where Loading Machines May Defeat Their Purpose

SEVERAL loading machines are idle, said Thomas F. Downing, Jr., general manager of the Logan County Coal Corporation, because the operator forgot that he would have to clean his coal and would have to obtain salable sizes, and the loading machine prevented him from doing this effectually. The fault is not with the machine but with the operator who failed to give proper consideration to this problem and chose the wrong machine for the particular seam he had to market.

One may save 20c. in the cost of loading, but the advantage thus gained must be obtained without losing that 20c. by decreasing the percentage of lump and egg which is produced for the market. The relative percentage of large sizes may readily be decreased 10 or 15 per cent, and if that occurs the operator has lost in one way what he has gained in another. Preparation begins at the face where the coal is shot down and even with the undercutter that precedes the shot.

Many operators have laminated beds of coal and cut in different parts of the seam. They may cut right under the lamination and pry the lamination loose and then load the upper bench. If they are going to use a loading machine they will have to satisfy themselves that they can find one that will load out the coal as it is loaded out by hand before they invest in such a machine, or they may find that they are unable to keep the impurities out of their product. Mr. Downing said he knew of no machine on the market that would do that satisfactorily.

When loading machines are used the operator must shoot down the whole seam. When he does that he is in dire trouble. Some manufacturers declare that with their machines the coal can be cleaned inside the mine. Perhaps some picking can be done underground, but most of it will have to be done above ground, and it will be necessary to provide the equipment to haul the impurities to the surface, separate them on the tippie and dispose of them when they have been separated.

Before deciding whether you can afford to load the refuse you have in the mine with the coal, pick out four or five places in the mine, have them shot in the same way they will be shot for machine loading, bring the coal out in the cars with the impurity it will contain when so loaded, run it over the tippie, have extra hands to pick it and wash it. Then you will be able to tell whether it is practicable for you to use machinery for loading your coal. Your tippie may be run intermittently and by storing your coal and running the picking tables slowly you may be able to clean the coal without new equipment or more men.

Some have said that if you break up the coal loading it mechanically, prepare more sizes, but one of the curses of the anthracite field is the number of sizes. I don't think the bituminous field should make the mistake of introducing such meticulous sizing into its market, which in most parts of the country is still free from it.

What Will It Cost and What Must Be Done to Keep Coal Mines Free from Dust Explosions?

Bright Claims Five Tons of Dust Should Be Distributed per Mile—Deike Says 1.8 Tons Will Serve After Roads Have Been Once Treated—Fear's Shale Costs \$3.70 per Ton

THE Friday afternoon session of the Cincinnati Exposition meeting, which George S. Rice termed "the first national gathering entirely devoted to rock dusting," was attended by about 150 men. John E. Jones, safety engineer of the Old Ben Coal Corporation, as chairman of the meeting, had suggested that the discussion of all papers be saved until last.

J. W. Paul was unable to be present, but he presented a paper on "Occurrence, Characteristics and Behavior of Coal Dust," which was read by Graham Bright. John E. Jones read an address entitled "Actual Experiences with and Tried Methods of Applying Rock Dust."

George Deike, president of the Mine Safety Appliances Co., read a paper on "Methods of Procedure," by John T. Ryan who was not able to attend because of sickness developed while aiding in the exploration work in the Benwood mine. A comparison of the inefficiency of water and the effectiveness of rock dust as means to prevent the propagation of coal dust explosions was made by Edward Steidle, supervisor of the Co-operative Mining Department, Carnegie Institute of Technology, in a paper on "Rock Dust vs. Water." Finally George S. Rice wound up the presentation of the problem by talking on the "Co-operation of the U. S. Bureau of Mines," in which he reviewed the past work of the Bureau and suggested what might be expected of it in the future.

BRITAIN'S MINES ARE DRIER

Mr. Rice pointed out the differences between the mines of this country and those of Great Britain, which influenced the latter country to go to rock dusting. Generally speaking the English mines are drier than ours, for which reason much water was required to hold down the dust. The application of water in large amounts to roof and ribs of the English mines caused spawling, with the result that the mines were rendered dangerous.

He advises every operator to experiment with rock dust to determine the best procedures to follow and to find out the relative cost as compared with that of sprinkling or humidification. Mr. Rice believes that in practically every case rock dusting will cost less than thorough watering.

Mr. Rice sees in mechanical loading the elimination of one of the biggest factors in the origin of coal dust. Mine cars loaded mechanically will not be cribbed high above the sides, to cause the spillage of coal by irregularities in the track or in the movement of a trip. Rock dusting does not remove entirely the necessity for the use of water, for

the latter should be used as an added safety measure in sprinkling trips and wetting down that part of a face in contact with the cutter bar of a cutting machine.

The U. S. Bureau of Mines has co-operated in the past by assisting individual companies, notably the Old Ben Coal Corporation, in testing and analyzing samples of coal dust and offering its experiences otherwise in the solution of problems relative to rock dusting. The Bureau is ready to aid any or all companies in applying rock dust and requests that its advice and service be sought.

L. P. Tracy announced that the Illinois Geological Survey is getting out a bulletin on the location of limestone measures in that state. This bulletin will be ready for distribution in a month or two; all those desiring a copy should write to the experimental station at Urbana, Ill.

WETTING IS MORE EXPENSIVE

Graham Bright took issue with some of the figures contained in John T. Ryan's paper. For instance, he said that Mr. Ryan appeared to be entirely too optimistic in saying that limestone dust in small quantities can be produced at \$1 per ton. The cost given for applying the rock dust also seems low and therefore the total cost of 0.44c. per ton of coal mined is hardly sufficient, according to the remarks of Mr. Bright, who based his remarks on conjecture alone. He is satisfied that if the cost of producing and applying rock dust is not more than 1c. per ton of coal mined, operators will be willing to adopt rock dusting. Certainly the average cost of wetting and humidification is greater.

The quantity of rock dust to be distributed, 1.8 tons per mile, as suggested by Mr. Ryan, did not meet with the approval of Graham Bright, who said that John E. Jones recommends 2 lb. of rock dust per linear foot of entry, or about 5 tons per mile. Mr. Bright closed his remarks by hoping that compensation rates will be reduced for all mines using rock dust. A reduction of this sort would be an impetus favoring the adoption of rock dusting in other mines.

George Deike answered several of the questions raised by Graham Bright. He said that the charge of \$1 per ton for crushing limestone to dust is based on the employment of no extra labor aside from that expended on a part time basis by regular outside company men. The quantity of 1.8 tons per mile represents the average quantity of rock dust required in each application when dusting is done systematically and at regular intervals.

Thomas Fear, general superintendent of the Inland Collieries Co., briefly stated his experiences with rock dusting extending over a period of three months. The Indianola mine has a capacity of 3,000 tons of coal per day. Entries and crosscuts total about 64 lineal miles. The usual rule is to apply 2 lb. of rock dust per lin.ft. of entry. Two men can apply about 4,000 lb. of dust per hour or 14 tons per shift, over a distance of 14,000 lin.ft. Shale taken from the roof of his mine is crushed on the job at a cost of \$3.70 per ton (not \$1 as given by Mr. Ryan). Mr. Fear believes that the total cost of applying rock dust per ton of coal mined will be no more than 4c. He expects to get credit for rock dusting in his compensation rates.

Experiments in the application of rock dust in the Indianola mine proved to Mr. Fear that with the particular types of distributing machines used (two kinds, fan and compressor types) the end of the nozzle should be held from 20 to 36 in. from the surface to be coated with rock dust. There is a definite relation between the characteristics of the distributor and the distance that the nozzle is held from the surface to be coated. An experienced nozzle man can apply a coat of rock dust to roof and ribs as much as $\frac{3}{4}$ to $\frac{5}{8}$ in. thick.

The desirability of heavily coating the ribs and roof was pointed out by Mr. Fear. He said that the floor represented approximately only one-fourth of the periphery of an entry. Though most of the rock dust tends to settle on the floor, an attempt should be made to coat the ribs and roof heavily, where it is undisturbed by the movement of haulage.

ROCK DUST IN STEMMING HELPS

Rock dust used in the stemming of shots adds safety to the blasting of coal. The rock dust is so fine that little of it is loaded out with the coal. It mingles with the coal dust. About 10 lb. of rock-dust stemming is used in each 6-ft. cut.

George Rice asked if the coating formed by rock dust on ribs and roof would retard the rate of weathering or spawling. Mr. Fear believes that it will have this effect. In his Indianola mine he expects to have less trouble with the roof which is bad, by the substitution of rock dust for water, and he is certain the cost of the former is considerably less than the latter.

Chairman Jones checked Mr. Fear's estimate that 4c. per ton of coal mined will cover the cost of applying rock dust. He said that is the actual cost for applying rock dust along 122,270 lin.ft. of entry in one of the Old Ben mines.

National Coal Association Elects S. P. Hutchinson President at Cincinnati Convention

In Quiet but Heavily Attended "Town Meeting" Sessions
It O. K.'s Mellon Plan of Tax Reduction, Pats Coolidge
on Back, and Hears Many "Outsiders" on Coal Problems

A "TOWN MEETING" style convention of National Coal Association in Cincinnati, Ohio, May 14-16, gave that body of bituminous coal operators a chance to speak its mind. Not much was said but the association did register, on the one hand, its approval of the Mellon plan for tax reduction and of President Coolidge's veto of the bonus and pension bills, and on the other hand, its disapproval of governmental interference in business, of the proposed plan for publicity of tax returns, the proposed surtax on undistributed corporation profits, and of the Coal Commission's suggested scheme for changing the basis of mine-car ratings.

The convention was not filled with big issues or fighting points. Main interest centered about the election of S. Pemberton Hutchinson, of Philadelphia, as president to succeed J. C. Brydon, who retired amid plaudits of the operators for the services he has rendered during the past year for the association and as chairman of the Bituminous Operators Special Committee.

The only contest for official position came on the floor of the convention when F. S. Love, of Pittsburgh, Pa., was nominated as a fifth candidate for the four directorships at large. The four nominated by a committee for the purpose and later elected were W. H. Cunningham, E. L. Douglass, Phil Penna and P. J. Quealy. In the voting the first three of these received almost the unanimous vote of the membership, while Mr. Quealy got 750 and Mr. Love 362. However, in a later session, Mr. Love was chosen a Pennsylvania director to succeed Mr. Brydon, who, as retiring president, automatically became a director ex-officio, thus leaving an unexpired term.

Association Sound Financially

The association was able to show that it had done a good deal of work during the past year at a minimum of cost, and assurance was given that no special assessments over the regular one mill assessment are contemplated during the coming year. The financial report showed the association to be in sound condition and the membership report indicated that had it not been for the recent withdrawal of the entire Southwestern Interstate Coal Operators' Association with its 125 member votes, the total membership would have been enlarged over the previous year.

Registration was heavier than it ever had been at any previous convention, a fact that must be credited in part to the presence in Cincinnati of the American Mining Congress meeting and machinery show, which ran simultaneously. The programs of both were arranged so as not to conflict. They touched at

one or two points, such as the "get together" dinner on the night of May 13 and at a luncheon of the Congress May 15, at which H. N. Taylor and W. H. Wright spoke.

There were many good words during the convention for Harry L. Gandy, executive secretary for the association, who has finished his first year with the organization and was re-elected with a spontaneous show of approval.

"LEAVE CAR RATINGS ALONE" SAYS NATIONAL

The National Coal Association, at its convention in Cincinnati last week, took a stand against any change in the present system of rating mines to receive cars, stating that the association "was opposed in principle to the use of a commercial factor in the rating of coal mines" as the U. S. Coal Commission suggested.

The resolutions committee had brought in a resolution favoring tax reduction without naming the Mellon plan. But T. W. Guthrie, of the committee, rose to insist that it be named. H. N. Taylor, also of the committee, and C. E. Bockus, chairman, explained that while probably all the members of the committee believed in the Mellon plan and could well campaign for it as individuals, yet it might be impolitic for the association, as such, to single out any one bill aiming at the desirable object of lower taxes. It might cause needless irritation in certain quarters in Washington.

The amendment was adopted by a vote of 16 to 12 and the resolution was passed.

In the opening session the morning of May 14 President Brydon, after a year of service, delivered a report without specific recommendations except suggestions that the association keep up the work it has been carrying on, to study labor conditions continuously, to compile facts about coal regularly, keep up the public educational campaign, and be prepared for any contingency that may arise. His recommendation last year that the presidency be put upon a full-time salary basis was not adopted by the directors last autumn because it was felt that expenditures should be kept at a minimum and because the executive secretary was able to assume many of the duties that might have devolved upon the president.

Mr. Brydon reviewed the work of the Bituminous Operators' Special Committee which served during the time of the U. S. Coal Commission's life. It submitted to the commission no less than sixty briefs setting forth the coal

industry's case. He spoke also of the plan worked out by the association last summer for emergency distribution of bituminous coal—a plan which can be put into effect whenever the necessity arises. He reported that the publicity efforts of the association had resulted in the sending out of 429,000 copies of briefs submitted to the Coal Commission and of Commission reports.

Incidentally he announced that the association is about ready to issue an annotated edition of all the reports of the commission—two 1,000-page volumes.

Harry L. Gandy, executive secretary, in his report spoke of the retrenchment program of the association and of its determination to give the members a maximum of service at a minimum of cost. The association maintains no continuing counsel, he said, yet the employment of counsel in such matters as the defense against Federal Trade Commission demands saved the operators of the country more than the defence cost.

Although various further reductions in expenditures will be made, he said it is necessary to keep up most of the statistical work of the association in order to meet the frequently arising need for exact and satisfying data on coal that is requested from so many sources and which has been used so effectively during the past year in the country-wide campaign of education.

He recommended that the association conduct systematic researches to place before the industry and the public approve modern methods of combustion and proper combustion appliances. Mentioning the publicity work he said *Coal Review*, the association's magazine, has lost money but that it has served a purpose and has saved the cost of issuing bulletins that otherwise would have been necessary.

The association is still operated on its ordinary 1-mill assessment and he gave assurance that no special assessments are in prospect. Increased revenue, if any, he said would come from increased membership.

The foreign trade committee reported with pleasure that Section 28 of the Merchant Marine Act will not take effect next month, as originally ordered. On May 8 the U. S. Shipping Board withdrew its certification from the Interstate Commerce Commission and that commission will cancel its order to the railroads. This leaves Section 28 under suspension indefinitely. This section provided that in order to get the benefit of the export rail rate to tidewater, goods exported had to move from the port in an American ship.

W. H. Cunningham reported for his committee on government relations,

mentioning its watchfulness over the legislative matters at Washington, which included scanning 227 bills of interest to coal and active participation in hearings on two. The May 7 hearings before the Mines and Mining Committee in the House on the general question of mine safety moved the committee to say this: "Opinions from the field indicate that while keenly appreciative of the necessity for carrying on mine safety work and education, yet local conditions should and do govern safety orders, and that it is hardly probable general orders could be issued from Washington or any other central point that would properly apply to the entire country, even if it be established that such a centralization of authority would be legal."

Publicity work for the year was of two classes, according to the report of C. E. Bockus, chairman of the committee on publicity. It covered publicity for the Bituminous Operators' Special Committee and regular association publicity. The first cost \$80,000, including \$22,000 for the speakers' bureau.

A brisk and interesting address on the service of trade associations was delivered by R. S. Kellogg, of New York, secretary of the News Print Service Bureau. He said such associations are needed keenly in an industry like that of coal, where there are so many small units and such diversity of interests among operators. A trade association is of service both by setting standards of commodities and practices and by gathering and setting forth facts to guide legislation and public thought in the best interests of the industry and the country.

At a final meeting and luncheon of directors, Charles W. Connor, of the Northeast Kentucky Coal Operators' Association, was chosen from that district to succeed E. L. Douglass. There was no Wednesday afternoon session so as to avoid conflict with the American Mining Congress meetings afternoons all week, but that evening Secretary Gandy delivered an address to the public on coal, its comparative inex-

haustibility and service to the people.

A good deal of outside viewpoint on coal was brought to the convention in the Thursday morning session, when speeches were made by President Samuel B. Crowell of the National Retail Coal Merchants Association; John Lee Mahin, head of a New York advertising agency; Melville E. Stone, president of the Associated Press, and George H. Cushing.

After 38 years in the coal business, not only as a retailer in Philadelphia but also as an operator and wholesaler, Mr. Crowell, speaking on "Our Customers," said they are really the employers of both producers and retailers and that both should join in thought and energy to hold the good will of those consumers.

From the retailer's standpoint he urged that as an economy measure the number of sizes of bituminous coal marketed be reduced. He appealed to the operators to devise some system of labor relations so that the supply of coal to the public will not be shut off every time there is a disagreement between miner and mine owner.

He advanced once more his idea for a "coal institute" backed by all the factions of the industry to better educate the public in matters relating to coal and to improve the economics and the methods of the industry.

Marketing of coal ought to be regarded with more foresight by the coal industry, according to Mr. Mahin, who is president of the Federal Advertising Agency. The industry may be too prone to listen to the opinions of men who consume coal directly. Instead, it should look beyond to the people who make use of the energy which is in the coal. It is the user of the railroad—the one who actually profits by the energy in the coal which the railroad consumes—who makes the coal market. Therefore, the coal industry should look broadly to him and cultivate him in order to merchandise properly the fuel it produces.

The head of the Associated Press, one of the world's greatest agencies for

collecting and disseminating news, contended for better co-operative effort between employer and miner.

Both operators and miners ought to recognize that they hold a trusteeship for the public. They have no right to exercise monopolistic control of the coal this country needs, and neither of them should be monopolistic in their own division of the work of the industry. He believes in competition, in the labor of coal digging, and in the selling of coal just as he does in the gathering and handling of news.

The complete list of new officers and the list of directors chosen to fill this year's expiring terms follow:

President, S. Pemberton Hutchinson, president of the Westmoreland Coal Co., Philadelphia, Pa.; vice-presidents, Ira Clemens, president, Clemens Coal Co., Pittsburg, Kan.; Michael Gallagher, general manager, M. A. Hanna Co., Cleveland, O.; George B. Harrington, president, Chicago, Wilmington & Franklin Coal Co., Chicago, Ill.; Walter Barnum, treasurer, Pacific Coast Co., New York, N. Y.; treasurer, C. E. Bockus, New York, N. Y.; executive secretary, Harry L. Gandy, Washington, D. C.

Directors-at-large: E. L. Douglass, Cincinnati, vice president, First Creek Mining Co., Kentucky; Philip H. Penna, Terre Haute, Ind., secretary, Indiana Bituminous Operators Association; Walter H. Cunningham, Huntington, W. Va., secretary, West Virginia Coal Operators Association; P. J. Quealy, Kennermer, Wyo., president, Gunn-Quealy Coal Co.

The following district directors were chosen: George B. Harrington, Chicago; L. C. Madiera, 3d, Philadelphia; George H. Tytus, Columbus; Walter Barnum, for Washington State; C. E. Bockus, New York City; Ira Clemens, Pittsburg, Kan.; M. L. Gould, Indianapolis; T. W. Guthrie, Pittsburgh, Pa.; W. H. Huff, Denver; W. F. McGeath, Omaha; T. F. Farrell, New York City; J. G. Puterbaugh, McAlester, Okla.; C. W. Taylor, Greenville, Ky., and S. L. Yerks, Birmingham, Ala.

Walter Barnum

Director of National Coal Association, Resident of New York and Seattle, Connected with Pacific Coast Coal Co.

S. Pemberton Hutchinson

Newly Elected President, National Coal Association, and President, Westmoreland Coal Co., Philadelphia, Pa.

Harry L. Gandy

Re-elected Executive Secretary, National Coal Association, Former Representative in Congress of South Dakota

New Equipment Shown at Cincinnati Convention

Many New Devices Making Mining Safer or Cheaper Exhibited—Pumps, Car Greasers, Track Equipment, Locomotives, Cars and Car Dumps Among Major Items—"Side Show" Attracts Much Attention

BY FRANK H. KNEELAND
Associate Editor, *Coal Age*
New York City

IN ORDER to enter the Convention Hall at Cincinnati, it was necessary for the delegates to pass into the Machinery Exposition. Here the booths of the exhibitors were arranged upon either side of three long aisles, with breakthroughs between them at suitable intervals, so that it was unnecessary for the visitor to pass to the end of an aisle in order to gain admission to another.

Although a vast amount of equipment and machinery useful to the coal producer was on display, no attempt will be made in these pages to describe or even enumerate all of the exhibits. Volumes might be written on such a subject without exhausting the possibilities of the show. It will be rather the intention here to take up briefly those pieces of equipment and devices that are new to the coal industry and which, therefore, are of particular interest to coal mining men. We will, accordingly, pass along the booths in approximately the order in which they were numbered, noting the various items or new equipment and apparatus as found.

In space 3, which was shared by the Roberts & Schaefer Co. and the American Coal Cleaning Co., G. R. Delamater had on exhibit what is known as the Delatester. This is an apparatus invented by the exhibitor who devised it as a ready means for quickly and

simply applying the float and sink test to coal. It is shown in Fig. 1. In this apparatus a complete separation of free pieces of coal from free pieces of slate or other impurities can be made by means of a solution that will float the coal but allow the impurities to sink.

The float and sink test is made by mixing a sufficient amount of granular commercial zinc chloride with water so that the resulting solution will have a specific gravity of, say, 1.60 and then depositing in this solution a sample of the coal to be tested and thoroughly stirring. Particles having a specific gravity of less than 1.60 will float, while those of a greater

Fig. 2—Gathering Pump

The vitreous china cylinder of this pump is proof against the attack of acid. Other parts of this machine coming in contact with the water are of bronze or other acid resisting material.

Fig. 1—Delatester Assembled

By use of this machine the float and sink test may be readily applied to a mixture of coal and slate to determine the possible advantages that may be derived from concentration, washing or other means for bettering quality.

Fig. 3—Lincoln Car Greasing Machine

By means of this machine a measured charge of grease is forced into each car bearing. On test one man has greased the four wheels of a car in one minute.

specific gravity will sink. The percentage of material that floats may then be determined and this material analyzed for ash, sulphur, etc., in the ordinary way. The sink may be treated in a like manner.

Similarly tests may be made on coal samples using a liquid of any desired sepecific gravity down to, say, 1.30. Ordinarily, as the specific gravity of the liquid is decreased, the percentage of material that will float in it will also be decreased, as well as the ash content of that portion of the material which floats. The float and sink test may be employed for preliminary investigations to determine the extent of improvement possible through concentration methods, or for the control of coal cleaning plants in general. As may be seen, the Delatester is a simple apparatus that may be readily operated by

Fig. 4—Coal Drill at Work

The post mounting of this drill is little heavier than that necessary for a hand auger yet allows the drill to be operated at any height above the floor and at almost any angle, thus assuring correct placing of the shots.

ground to size inside with the ends faced off in a like manner. This is held in place by three long bolts extending between the front and rear cylinder heads. They not only hold the rear head in place, but clamp the entire cylinder to the pump frame. The two cylinder heads are joined to the valve chest by their upper flanges. The removal of five nuts (two from the bolts joining the rear cylinder head to the valve chest and the three from the tie bolts) permits the cylinder to be withdrawn. The piston is normally packed with square flax packing. The valves are of rubber working on bronze seats.

Although bronze was used in the metal parts of the pump on exhibition, for handling water of medium acidity cast iron parts might be employed. Specific advantages claimed for this pump by the manufacturers are: That the china cylinder being entirely immune to the action of acid, undergoes no deterioration in use

Fig. 5—Five Oxygen Cylinder Manifold

Although this manifold weighs only a few pounds and when taken apart may be packed in the regular tool kit, by making available the oxygen contained in five cylinders it permits the completion of a fair sized job without interruption.

almost any one after a little practice.

In space 10, the Deming Co. exhibited a mine gathering pump fitted with a vitreous china cylinder. This pump is intended for handling extremely acidulous water and is shown in Fig. 2. It is provided with a bronze valve chest, and in every other way made as nearly acid proof as possible. The cylinder or barrel is a plain straight cylinder or short tube of hard unglazed vitreous china,

except that arising from the friction of the piston. The china resists abrasion from grit in the water far better than would bronze, it being so hard that a fragment will readily scratch glass. No relining of the pump is necessary, and inasmuch as the cylinder may be turned in any desired position all of its inner surface may be worn away evenly.

The Lincoln Steel & Forge Co., occupying booths 15, 16 and 17, among other equipment showed its new car-greasing machine. This consists of two grease tanks of about 500 lb. capacity each, one of which may be used while the other is being filled or both may be used simultaneously. Two grease pumps are employed, both of which draw from either tank. A measured charge of grease is drawn into one of the pumps, the hose nozzle from this pump is inserted into the grease chamber of a car bearing and the grease cock opened. A measured charge of grease is thus forced, under pressure, into the bearings, after which a warning signal sounds and the grease cock is cut off. The machine is then ready for the next bearing without any appreciable wait.

The size of grease charge administered to each bearing is readily adjustable by moving a collar on the vertical piston rod. This adjustment takes but an instant to make and the charge may be varied between about $\frac{1}{2}$ and 2 lb. On test, a car (four wheels) has been greased by one man in less than one minute. The entire machine is mounted on a regular-gage car truck and may be taken anywhere, where mine track is available for its transportation.

The total weight of this machine with the tanks empty is about 1,400 lb., or approximately 2,400 lb. with both tanks full of grease. A single-tank machine is

This frog is made from a tough alloy steel intended to withstand over long periods the rough usage to which all mine track equipment is subject.

also made. The double-tank type, however, permits the greasing of cars from both sides of the track simultaneously, or the filling of one tank while the other is being emptied. An air compressor may be supplied on the machine, or air may be drawn from the mine air system if available.

In booth 38, the Chicago Pneumatic Tool Co. had on exhibition its Little Giant coal drill fitted with a portable post mounting. This machine is shown in Fig. 4.

Fig. 7—Hoist Indicator

This is an overwind preventor and speed governor as well as a position indicator. Attachment to the hoist drum may be made upon either side.

change of augers in drilling the deepest shot-holes. It is unnecessary to remove the feed bar in order to change augers, as a split nut enables this bar to be slipped through it to its rearmost position. This saves much time both in setting up the drill and in changing augers.

The Oxweld Acetylene Co., occupying booth 40, among other useful devices had on exhibition its five-cylinder, portable oxygen manifold. This manifold is small and of light weight, designed especially for work in the field. By its use five oxygen cylinders can be connected together, thus supplying a sufficient amount of oxygen for a considerable job. This device weighs only 10 lb. and when taken apart may be carried in the tool kit.

In detail, this manifold consists of a hexagonal brass block with six connections, five for the cylinder and one for the regulator. Four of the five cylinder con-

The mounting here employed is especially designed for use with Little Giant drills. It is light in weight and can be readily set up by one man as quickly as a post for a hand auger. When in operation the weight of the drill itself is borne by the mounting, thus permitting the proper placing of top holes in high coal. The feed bar is 5 ft. long, which necessitates only one

This clamp holds the guard rail securely in position without the use of either bolts or spikes.

nections are at the ends of flexible, double-coil copper tubes, while the fifth is short and rigid and connects the block directly to the valve of the cylinder, thus serving as a support for the entire manifold. The oxygen regulator is coupled directly opposite this rigid connection. When less than five cylinders are employed, the extra connections are closed by means of caps attached to the block by chains. A manifold of this kind is particularly useful in small shops that do not handle a sufficient volume of work to warrant a 10-, 20- or 30-cylinder manifold. This device is shown in Fig. 5.

In booth 57, the Cincinnati Frog & Switch Co., among other exhibits, showed its cast steel mine frog. This is illustrated in Fig. 6. The chief point of excellence of this frog is the alloyed steel of which it is made. This is an extremely tough metal intended to endure indefinitely the pounding and rough usage to which all track appliances in the mines are inevitably subjected.

In booth 65 the Duro Metal Products Co. had on exhibition several of its speed indicators for hoist engines, one of which is shown in Fig. 7. As may be seen, this is an extremely simple device, thoroughly protected from dust and dirt. The governor in this indicator is dampened by an oil dash pot, so that sudden changes of speed or jerks will not cause it to become operative and shut down the hoist prematurely. As may be seen in the figure, the drive shaft is available for connection to the hoist upon either side. The side chosen should be the one where best protection is secured and where it will be out of the way of workmen. As a rule, this controller must be positively driven in a proper ratio from the hoisting drum shaft. Steel roller chain and cut steel sprockets are employed for this purpose. The standard drive speed is 130 r.p.m. and the gears employed are arranged to afford a maximum amount of dial movement for the full travel of the cage.

Booth 71 was occupied by the Rail Welding & Bonding Co. The bonds used by this firm instead of being

Fig. 8—Brazing a Bond to the Rail

First the terminal is gripped in a mold which is fastened in proper position. Next the electrode is fed down until the mold is full of molten metal. This is allowed to cool before the mold is removed. In this way the bond is effectively brazed to the rail and a good electrical contact made.

welded, steel to steel, on the rail are attached by what practically amounts to a brazing process. As may be seen in Fig. 8, the ends of the bonds are clamped in a suitable mold after which a metal electrode of the proper composition is applied until the mold is full of molten metal. This adheres to the bond terminal and likewise to the rail. The contact area between bond terminal and rail secured by this means is from four to six times the cross-sectional area of the bond cable. This furnishes a large factor of safety and is an excellent electrical connection because the copper bond head is welded or rather brazed direct to the steel rail.

In booths 74 and 75, the Weir Frog Co. showed its Titan guard-rail clamp intended for light rails. This clamp is shown in Fig. 9. It consists of a yoke of heavy forged steel shaped to fit the rails and a steel key tapered where it fits the yoke. When this key is driven up tight, there is no chance of the guard rail rolling or tilting out of position. No spikes, bolts or rail braces are necessary with this clamp. It is now manufactured in sizes to fit rails weighing from 25 to

Fig. 10—Acid-Resisting Valve

All parts of this valve coming in contact with the water are made of wood or rubber. Extremely acidulous water accordingly may be handled by it without injury.

45 lb. per yd., and is especially adapted to tracks where motor haulage is employed.

A decidedly unique device designed to contend with extremely acidulous water in mine drainage was shown by Bennett & Meyer in booth 85. This consisted of a line of valves, all parts of which coming in contact with acid water were composed of wood. A valve of this kind is shown in Fig. 10.

These valves which may be made in the angle straightaway globe and check types, may be fitted for connection to screwed or flanged metal pipe or to the ordinary wood stave pipe employed under extremely acidulous conditions. The valves are so built that a wooden disk bears on a wooden seat. As a variation of this construction, a rubber seat may also be employed.

In booth 56 the General Automatic Scale Co. had on exhibition its Weightograph. This is practically

an automatic scale wherein the weight indicated is projected onto a ground glass in front of the observer. The figures showing the weight are engraved on a small quadrant within the machine behind which an electric light is placed in such a manner as to project the

figures before the eyes of the weighman. When a load is placed on the scale, it is balanced and indicated promptly and automatically by one moving member. As the scale is depressed by the weight of the load, the light flashes on and the chart revolves into position, showing the weight on the reading screen in large illuminated figures and graduations. This gives a clear plain reading that can be seen from any angle and almost any distance. This device at a mine renders it necessary only for the weighman to record the weight indicated. It is shown in Fig. 11.

In booths 91, 92 and 93, the Enterprise Wheel & Car Co., along with other equipment, showed a new car of interesting design and large size. This is shown in Fig. 12. This car is especially adapted to machine loading, as it stands only 36 in. above the rail. The car box is 10 ft. long inside, 6 ft. 8 in. wide and is 24 in. deep. The length over the bumpers is 12 ft. and the weight 4,300 lb. It is a solid body car intended for use in connection with rotary dumps.

At the end of the right-hand aisle in the Exhibition Hall, in a space which might have been designated as 96-A, the Davies Mine Switch Lock Co., Inc., showed a model of its solid and automatic mine switch locks.

Fig. 11—The Weightograph

The weight on the scale platform is shown in illuminated figures. The weighman accordingly need only record the figures shown by the machine. No shifting of beam weights is necessary.

Fig. 12—Large Car Intended for Machine Loading

This view is looking almost directly down into the car box. Only by getting alongside this car can its unusual size be appreciated adequately.

Fig. 13—A Switch Lock Installed

This lock not only forms a bed plate supporting the switch point but when the point is thrown and the tongue folded down the switch is locked in position.

One of these is shown in Fig. 13. This device is intended to lock the switch latches of rails weighing from 25 to 40 lb. per yd. It consists of a chair or plate upon which the rail rests, and to which is fastened a tongue, which when the switch is thrown may be folded over securely locking the switch point in position.

This device is simple in construction and may be readily and easily installed. It can be adjusted to fit any size of lock or switch point and its use will eliminate, so it is claimed by the maker, the numerous difficulties encountered in present-day operation such as spreading of the track gage, tilting of the rails, lowering of the latch point below the rail level, or the springing open of the latch. It will also obviate the use of wood either to support the latch or to hold it in position, likewise the holding of the latch in position by hand when a trip is approaching, or the accidental disengagement of the latch through the stubbing of the toe by either a man or mule, and the slewing or pushing of cars to make them take a switch.

Alongside of this space, or in what might have been called booth 96-B, the General Mine Equipment Co., of Birmingham, Ala., showed moving pictures of a new gravity-operated rotary dump. This device is the invention of William R. Coleman, of Birmingham, and is intended for use with solid body cars. It is particularly applicable at slope mines, although it may be installed at any operation suited to any rotary dump.

This dump is so designed and constructed that a trip of cars coming out of the slope may be hauled through it and then lowered back by gravity, the dump automatically discharging one car at a time. As may be seen in Fig. 14, only one man, the weighman, is located in its vicinity. The operation of the device is entirely automatic, except that when a car of slate or of rock is to be discharged the weighman throws a lever whereby this material is dumped into a separate bin from that receiving the coal. The advantages claimed for this device are as follows: It uses solid body cars; there is no wastage of coal on the slope; it requires no switching, spragging or uncoupling of cars and dumps continuously; the cars feed and spot themselves automatically, while the oil-cylinder con-

trol of this machine prevents shock or vibration; it entails minimum degradation of coal and no power other than the force of gravity is required for its operation; the machine is entirely automatic and will discharge a minimum of five cars per minute; only one man, the weighman, is required. The construction necessary for its installation is decidedly simple; it may be built to accommodate any size or type of car.

In booths 104 and 105, the Irontron Engine Co. had on exhibit its storage battery locomotive, type WLS, especially designed for low coal. This machine stands only 25 in. above the rail, yet has a storage capacity of from 30 to 40 kw.-hr., depending on

the type of battery used. The effective length when rounding curves is 10 ft. 6 in., while the width is made equal to that of the cars employed. The total weight of this machine is from 5 to 6 tons, varying with the type of battery. It is fitted with band brakes on the drive shaft and a worm drive. In appearance this machine seems to be extremely rugged while it is also convenient in operation. All control devices are so located as to be readily within the reach of the locomotive driver, even when because of low coal he must lie on his side on the bottom plate of the machine.

In booth 100, the Cincinnati Electrical Tool Co. showed various electrical devices particularly applicable to mines and mine shops, among others was this company's one-man electric coal drill for boring shotholes. This machine is intended to make holes from 1½ to 1¾ in. in diameter and is wound for 250 volts, direct current. It weighs only 22 lb., and is said to be the lightest machine of this capacity at present on the market. This machine has been tried out in both anthracite and bituminous coal and after six months of operation is said to work satisfactorily in every way.

Booth 112 was shared by the Flexible Steel Lacing Co. and the McKinlay Mining & Loading Machine Co. The latter firm exhibited a model of a new mining machine intended to drive an oval or elliptical heading. This machine consisted of two cutter-heads revolving in opposite directions and a cutter chain which removed or cut away the triangular segment left by them. Although the idea of the revolving cutter-head is by no

Fig. 14—Gravity Operated Rotary Dump

This dump needs no power for operation other than the force of gravity. It automatically feeds, spots, dumps and releases the cars. A trip need not be uncoupled during the dumping process thus saving much delay.

means new, several unique features have been added to this machine. Thus lump coal is produced by what might be termed revolving weights, working in the slots made by the cutters on the revolving heads. The coal cut down is delivered to a belt conveyor of adjustable length and is eventually loaded into cars on the heading. The machine is forced forward to its work by means of hydraulic jacks. While apparently heavy and cumbrous, it is in reality extremely simple and cuts an almost ideal heading in the coal.

In booth 81, among other exhibits, the Watt Mining Car Wheel Co.

showed model cars equipped with a device known as the Bulldog automatic coupler. This device is shown in Fig. 16. The construction of this coupler, as may be judged from the accompanying photographs, is decidedly simple and few parts are employed. The coupler will operate upon straight track or upon any curve found in the mines. Lost motion between cars is practically eliminated and the labor entailed in coupling and uncoupling is saved. It is estimated that about 6 per cent of mine accidents occur in the operation of coupling cars and the makers of this device claim that its installation will eliminate this danger entirely.

One of the reasons for making the present hitchings of mine cars long, allowing considerable play between adjacent car bumpers is the fact that an uneven track causes a decided relative vertical movement between the car ends. This automatic coupling is so arranged as to provide for this movement without possibility of the cars becoming detached from each other.

Booth 45 was shared jointly by the Timken Roller Bearing Co. and the Dodge Manufacturing Corp. This latter firm had on exhibition its Timken-equipped shaft hanger intended for use on line shafts of all kinds. This device is applicable to any type of hanger using a four- or two-point suspension. The bearings proper are manufactured by Timken and marketed by the Dodge company. The saving in power effected by this use over that entailed by ordinary plain bearings is 10 to 50 per cent, depending upon conditions.

The bearing proper consists of two Timken roller bearings mounted on a ground steel tube and fitted with an accurately machined cast-iron housing. Grease seals are provided and two clamping collars are mounted on the threaded ends of the steel tube. This tube is slotted at either end, and is held to the shaft by the two collars which are also used to obtain accurate

Fig. 15—Low Storage-Battery Locomotive

This machine is so low that it could pass under a table. It is fitted with band brakes and it is claimed that the motorman can slip the drivers by the pull of one finger on the brake lever.

adjustment of the bearings on the steel tube. This adjustment is made at the factory and need not be altered by the user. Housings of this kind are adapted for use in practically any type of hanger. The mounting of the tapered roller bearing as described insures full utilization of the bearing for both radial and thrust loads. It also provides a bearing of great ruggedness and is of particular value in resisting the side weave of heavy driving belts.

The method of fastening the bearing sleeve to the shaft permits its use on ordinary commercial shafting which may vary slightly in diameter. The sleeve is fastened to the shaft by setting up the set screws in each of the clamping collars. Space between the housing and sleeve is filled with grease which supplies lubrication over a long period.

The foregoing are a few of the "high-spots" in the equipment exhibited. As stated in the beginning, volumes might be written on the show as a whole without exhausting its possibilities. It would hardly be just, however, to conclude any description of the exhibition at Cincinnati without mentioning what might be termed "the side-show." This was a tent in rear of the Exhibition Hall, in which two loading machines were shown at work. The operation of rail bonding was also exemplified. Almost everyone who visited the Exhibition Hall also paid a visit to this tent in the rear, where those inexperienced in the use of loaders gained a clear idea of how these machines were operated and acquired a reasonably accurate conception of their possibilities in actual use underground.

Taken all in all, the exhibition of machinery at this convention was a decided success. Upon all sides one heard the opinion voiced that the convention of 1924 was the most successful meeting of its kind ever held by coal men anywhere.

Fig. 16—Automatic Car Coupling and Its Parts

This coupling will operate upon any curve and its component parts are few and strong. Vertical movement between the car ends does not disengage the drawheads. Lifting one of the hooks uncouples the car.

News Of the Industry

Farrington Dominates on All Issues At Illinois Miners' Convention

Two-to-One Majority Sustains Peace with Lewis—Illinois President
Threatened with Howat's Fate—Deposed Kansas Leader
Says He Was Not Expelled from Union

(Special Dispatch to Coal Age)

Peoria, Ill., May 19—Frank Farrington, district president, tonight still held the whip hand over the biennial convention of the Illinois Miners' Union, supported by a two to one majority on all issues. His "peace" with International President Lewis was approved, as also was his "desertion" of Alexander Howat, deposed Kansas president, whom he charged in an address with joining W. Z. Foster and the communists at a Pittsburgh (Pa.) conference.

Farrington told the convention that Lewis had also threatened him with Howat's fate. Howat also spoke, saying he had been informed by Secretary Green two weeks ago that he had never been expelled. He said he had returned to work in the Kansas mines and wanted nothing but readmission to the union. He said he desired no back pay, nor anything but justice. He asked Illinois miners for "moral support." Decision was deferred. It is probable that the convention will adopt Farrington's proposal to investigate the feasibility of giant power plants.

Would Amend State Mining Law

Resolutions adopted by the convention included the following:

Demanding amendments to the Illinois state mining law, as follows: (1) Prohibiting mine examiners from carrying an open light into the mine, and compelling operators to provide an electric safety light for them.

(2) Requiring that there shall be an attendant at any and all doors in coal mines in the State of Illinois, to replace the present provision which is "that in any or all mines where doors are constructed in such a manner as to open and close automatically, attendants and places for shelter shall not be required." Such an amendment, the resolution says, if strictly complied with, would prevent "75 per cent of mine explosions," by preventing dangerous accumulations of gases, resulting from drafts caused by open doors. Automatic doors are unsafe, the convention was told, for the reason that chunks of coal get in the way, and sometimes the mechanism fails to act.

(3) Limiting the speed of mine locomotives or motors.

(4) Prohibiting coal companies from

turning a current of electricity into any coal mine until the mine has been examined for gas in all parts of the mine where wires are located.

(5) Requiring that all rooms in a mine, except those sealed up, both in old and new works, shall be examined by a mine examiner four hours preceding the day shift or night shift.

(6) Requiring coal companies to arrange separate compartments in wash houses, whereby miners could have their mining clothes in one compartment and their clean clothes in another, and so arranged that coal dust, grease and other dirt could not soil the clean clothes.

(7) Prohibiting miners from carrying into mines in their pockets detonating explosives, caps and detonators.

(8) Requiring two men on moving motors and mining machines.

(9) Requiring every mine to have its own shotfirers, thus abolishing the system in some places which requires each individual miner to shoot his own shots.

Considerable debate was occasioned by a resolution which demanded that "it shall become a part of our agreement, after April 1, 1924, that all operators must be bonded for all payrolls, and also compensation bills where they are not protected by some reliable insurance company."

President Farrington addressed the convention regarding this proposal. He said the only thing that could be done with it was to refer it to the scale committee which meets the operators three years from now. He said the only recourse miners have against operators who fail to pay their employees wages before closing down is to forbid them reopening until all back wages are paid.

Dan Harrington Leaves Bureau of Mines

Dan Harrington, Bureau of Mines engineer for years in the Rocky Mountain region, joins the Utah Fuel Co. and the United States Fuel Co., both of Salt Lake City, July 1 as consulting engineer in safety. His place in the West for the Bureau will be taken by Albert A. Munch, of the Pittsburgh, (Pa.) experiment station.

Hardwood Men to Compile Trade Data Soon Again?

The compiling of statistical information may soon be resumed by the American Hardwood Institute, one of the leading participants in the fight for trade statistics. At Louisville, Ky., May 9, the Institute gave its board of directors permission to re-establish the statistical program whenever the board feels that it can do so safely. The Hardwood people stopped compiling statistics some years ago as a result of interference from Washington, re-established the department, and again stopped it in January of this year, when the then Attorney General Daugherty wrote an unfavorable letter to Secretary Hoover.

Miner Plotters Confess

It was reported from Madisonville, Ky., on May 10, that Sam Coffman, of Madisonville, and Tom Richardson, formerly of William County, Ill., had been arrested and were in jail at Madisonville, charged with "confederating and banding together" in connection with an alleged plot to dynamite a plant of the Hart Coal Corporation, last February. Richardson confessed the plot and implicated Coffman, and also a member of the United Mine Workers office at Madisonville, who couldn't be apprehended at the time of the other arrests. A written confession was made by Richardson to County Attorney Franklin. The Hart Corporation has had some trouble in camp for months past as a result of going non-union.

Shipping Board Bids Fall Within Narrow Range

Bids received by the U. S. Shipping Board at New York on May 16 for furnishing and delivering alongside vessels operated by the Board in New York harbor of 1,430 gross tons of bituminous coal containing a minimum of 14,500 B.t.u. resulted in prices ranging from \$5.17 to \$5.48 per gross ton, or from about \$1.92 to \$2.09 per net ton f.o.b. mine. There were four bidders: Imperial Coal Corporation, \$5.17; H. B. W. Haff, \$5.39; W. A. Marshall & Co., \$5.20, and Seiler Coal Co., \$5.48. These prices compare with about \$1.92 to \$2.77 net ton f.o.b. mine in the bids opened by the Shipping Board on May 12, when 18 bids were received for furnishing and delivering alongside upward of 216,000 gross tons.

British House of Commons Rejects Labor Measure to Nationalize Coal Mines

The mines nationalization bill was rejected by the British House of Commons May 16 by a vote of 264 to 168. The bill was introduced by George Henry Hall, Labor member, a Welsh colliery checkweighman, who said that nationalization had been demanded by the miners for a generation.

While agreeing with the principles of the bill, the Labor government took a cautious position, it being stated on behalf of the Cabinet that the Ministry disapproved of certain clauses, and consequently the bill was allowed to stand on its own feet as a private member's proposal.

Mr. Lloyd George declared the bill was the first concrete example of the new socialism which was to be put into effect as soon as the Labor Party got a majority. He declared that in addition to giving the miners the right to strike, the bill gave the same right to officials of the Mining Council, which meant that they could participate in a strike against a decision of the council, of which they were members.

Calls It Gigantic Trust

He stressed the fact that so much attention was paid in the bill providing for losses, the money for which was to come out of the public funds, while if profits were made they were to go back into the industry. This was not nationalization, he insisted, but a gigantic coal trust in the interests of one section of the community.

Mr. Lloyd George agreed that mining conditions were unsatisfactory, but he reminded the House that the Labor Party had rejected the government's ameliorative proposals of 1919. At the same time he was sure the House would not examine in a niggardly or partisan spirit any broadminded proposals to improve the miners' lot.

Emanuel Shinwell, Parliamentary Secretary of the Department of Mines, explained that while the government recognized that no mandate had been obtained from the electors to pursue a policy of nationalization, they heartily accepted the vital principle embodied in the measure. There was, he said, no solution of the problem confronting the mining industry, whether regarding production, distribution or utilization of the commodity, other than was to be found in national ownership. Sooner or later the principle would be accepted by the nation as a whole.

Sir Douglas Hogg said the present bill would be unjust to the miners, dishonest to the state and wholly inequitable to the interests of the consumer, and was deliberately devised to carry class warfare, not of one class against another but of one class against the community.

Mr. Smillie said it was the duty of the government to carry the bill into law. It was not only the miners but the whole trade union movement which was pledged to it.

Some Miners Manage to Keep Wolf from Door

Net income tax returns of \$9,100 each for the year 1923 have been filed by two employees of the Soper-Mitchell Coal Co., of Morgantown, W. Va. Both men are coal cutters. Another miner employed at the same plant filed a return for \$6,500 with an apology for its size, stating he did not have steady employment. Another man reported \$2,700, claiming \$7,300 exemption for his wife and 12 children.

More Pennsylvania Companies Revert to 1917 Scale

Following the lead of the Keystone Coal & Coke Co., the Hillman Coal & Coke Co. has made a wage reduction of 20 per cent at its Edna mines, Westmoreland County, Pennsylvania. The men at Edna No. 2 mine accepted and are working 100 per cent, but those at Edna No. 1 mine refused to accept the cut and are idle. This is in the Irwin gas coal basin.

In the same field, the Whyel Coal & Coke Co., whose two plants have been idle for several months, attempted to resume operations May 1 at a 10 per cent wage reduction, but the men objected and these mines are still idle.

In Somerset County all the companies (including the Consolidation Coal Co. and the Hillman Coal & Coke Co.) except the Berwind-White Coal Mining Co. reduced wages to about the 1917 scale and are working part time without any trouble. Union mines in the Pittsburgh and adjoining districts are getting slim picking, where they are working at all.

Connellsville Coke Operation Cuts Wages 20 per Cent

The Lincoln Coal & Coke Co., Scottsdale, Pa., a merchant coke operator in Lower Connellsville with 300 ovens, on May 1, reduced wages 20 per cent from the Frick scale, outside day labor being cut from \$5.40 to \$4.32 and common day labor from \$3.60 to \$2.88. The company then had 200 ovens in operation. No business was forthcoming, however, and the 200 ovens have since been blown out. The men accepted the cut without question and work continued long enough to show that the reduced wages were actually in force.

Other coke operators are considering wage reductions, as this was the first reduction at a regular Connellsville coke plant. The prediction now is that before long many independent operators will reduce, and that then the Frick company may follow.

One More Illinois Merger

The expected consolidation of Big Creek Coals, Inc., and the Harrisburg Colliery Co., both in southern Illinois, has taken effect. The new name of the company holding and operating the several Big Creek mines and the one 4,000-ton Harco mine is the Saline County Coal Corporation, headed by Charles I. Pierce, of Chicago, former president of Big Creek Coals, Inc., which only two months ago bought the Harco mine. The corporation controls 28,500 acres of land in Saline and Fulton counties, 8,565 acres of which is owned in fee and the balance held on long-term leases, principally from a subsidiary of the Big Four railroad. The total capacity of the group of mines is rated at 15,000 tons per day. The corporation is issuing \$2,500,000 of 6½-per cent 20-year bonds.

Courtesy U. S. Distributing Corp.

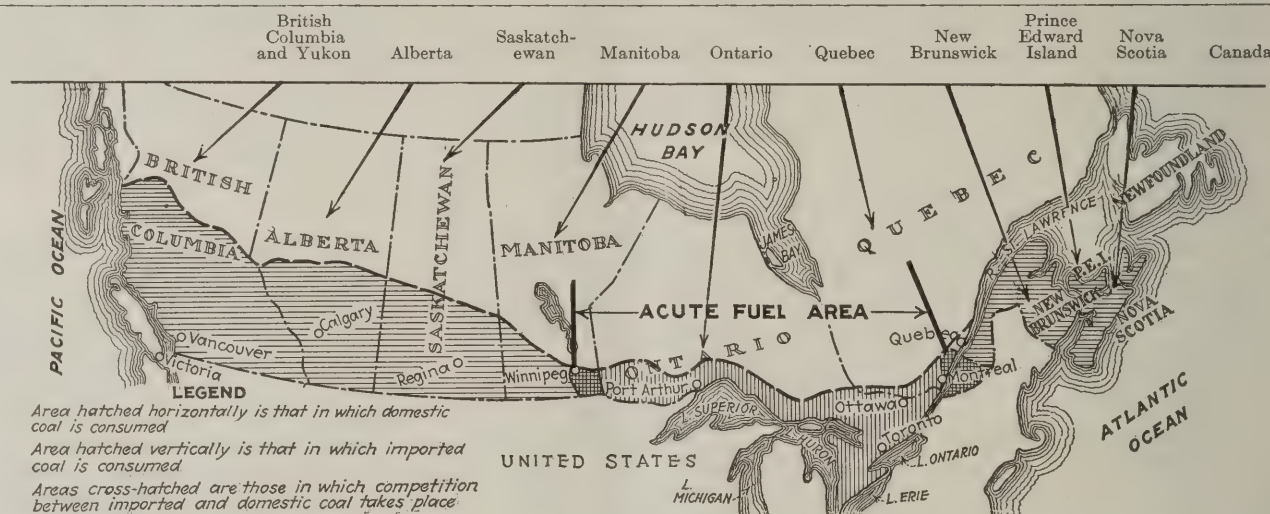

Loading Coal Into Barges on the Hudson River

At Edgewater, N. J., one of the upper ports of New York Harbor. Most of the principal Eastern railroads have coal terminals on the New Jersey side of the river, where coal destined for New York is dumped into barges for shipment across the river. In the distance some of the buildings on the west side of midtown Manhattan are discernible.

Coal Output, Exports, Imports and Consumption By Canada in 1923

(Preliminary figures, in Net Tons)

	British Columbia and Yukon	Alberta	Saskatch- ewan	Manitoba	Ontario	Quebec	New Brunswick	Prince Edward Island	Nova Scotia	Canada
Output.....	2,823,317	6,848,538	439,892	785,314	80,755	1,540,283	276,603	80,916	6,595,672	16,984,022
Received from.....	108,676	18,054	1,249,549	877	3	561,258	32,112	2,175,220	4,424,805	4,424,805
Shipped to.....	62,151	1,933,144	222,178	8,213	17,212,768	4,976,898	115,364	679,771	1,654,406	1,654,406
Exports (1).....	838,063	605	11,510	167,990	17,292,646	6,517,178	192,625	5,566	106,036	22,687,320
Imports (2).....	20,429	1,110	3,898	945,091	17,292,646	6,517,178	883,010	86,482	3,846,717	38,016,936
Consumption (4).....	2,052,208	4,933,953 (3)	1,459,651	17.8	99.8	76.4	21.8	6.4	2.7	60
Foreign imports in per cent of consumption.....	0.01	0.03	17.8	99.8	76.4	21.8	6.4	2.7	60
Coal equivalent of developed water power (annual) (5)....	3,318,000	298,000	1,458,000	13,009,000	10,058,000	401,000	20,200	492,000	29,554,000

(1) Statistics give exports by port of exit, not by province of production. For instance, the bulk of that exported from Alberta is shipped via Fernie and Cranbrook, B. C.

(2) Total imports were 22,687,000 tons, of which 530,000 or 2.3 per cent, were from Great Britain.

(3) Over 2,000,000 tons supplied to railroads for traffic east and west.

(4) Production plus imports and minus exports.

(5) On basis of 9 tons per installed turbine horsepower per annum.

Big Coal Development at Cape Breton Island

The Atlantic Coast Collieries, Ltd., has been incorporated with a Nova Scotia charter and will immediately develop coal areas located at Mabou, on the west coast of Cape Breton Island.

The company will own a large amount of land at or adjoining the mine property, on which will be located a power plant, bank head and other surface equipment together with railway yards, sidings and $7\frac{1}{2}$ miles of standard-gauge railway connecting the mining property with the Canadian National Rys. at Mabou Station. The company also will hold under lease from the provincial government an area of 17 square miles, partly on land and partly submarine, all in the neighborhood of Mabou. This property contains four workable seams of coal of proven thickness and quality, viz: 7 ft., 8 ft., 15 ft. and 5 ft., in the order named. There also are three other known seams, viz: 11 ft., 4 ft. and 3 ft., which have not been proven and are not taken into consideration.

The report of A. J. Tonge, chief engineer and superintendent of mining operation, states that the amount of coal in the property is estimated at 400,000,000 tons, but partly owing to the uncertainty as to the depth of the seams may

attain seaward and partly owing to the possible inaccessibility of a portion of the area, particularly on the south side, it is estimated that within two miles seaward of the slope mouth and within reasonable working distance from the slope there are approximately 150,000,000 tons of coal.

The board of directors are as follows: President, Charles Fergie, president and managing director of the Intercolonial Coal Co. and vice-president of W. A. MacKenzie & Co.; A. H. Whitman, managing director of Robin, Jones & Whitman, Ltd.; A. J. Tonge, chief engineer and superintendent of mining operations; J. McG. Stewart, solicitor, of Henry, Harris, Rogers & Stewart; James Stewart, colliery owner, and George Ross, president of Ross & MacDonald, Inc.

An offering of \$4,000,000 7-per cent 20-year bonds of the company is to be made soon.

Rock Dust Expert Tours West

J. E. Jones, safety engineer for the Old Ben Coal Corporation in Illinois, is now on a special tour of the Rocky Mountain region preaching the doctrine of mine safety by rock dusting under direction of the Bureau of Mines. Mr. Jones, after years of study and experimentation in rock dusting in the Old Ben mines of southern Illinois, is recognized as one of the country's experts in the subject.

New Freight Rates Benefit Southwestern Field

The one element in the coal situation which is heartening to the coal producers of the Southwest Interstate region, comprising Kansas, Oklahoma, Arkansas and Missouri, who recently signed up for three years at practically the old contract with the union, is the new set of lowered freight rates from mines to principal markets. The rates help the operators to meet stiff Illinois and far western competition in the Missouri Valley territory, and take effect June 5 by railroad initiative although they were ordered for July 10 by the Interstate Commerce Commission. The following table tells the story:

	Present Rate		Rate Ordered	
	Lump	Slack	Lump	Slack
To Kansas City				
From				
Rich Hill.....	\$1.46	\$1.22	\$1.45	\$1.05
Pittsburgh.....	1.70	1.34	1.65	1.25
Arkansas-Oklahoma	3.28	2.31	2.65	2.25
Spadra.....	3.40	2.31	2.90	2.25

New National Coal Association President Well Known to Official Washington

Was Active in Capital as Member of Wilson Industrial Conference and Industrial Rights League—Record Notable for Fair Dealing with Consumer—Is Authority on Labor Relations

BY PAUL WOOTON
Washington Correspondent of *Coal Age*

Selection of S. Pemberton Hutchinson as the new president of the National Coal Association has aroused much interest in various official quarters in Washington. Those officials whose duties bring them in contact with the coal industry are acquainted with Mr. Hutchinson, who has been a frequent visitor to the capital. He spent much of his time in Washington during the war, when he was connected with the Railroad Administration. Later he attracted official attention because of the part he played as a member of President Wilson's industrial conference. His duties as chairman of the League for Industrial Rights, which formerly had its headquarters in the capital, also brought him in contact with administrative officials and members of Congress.

Official Washington is interested particularly because it attaches deep significance to the National Coal Association. Most officials regard it as an essential organization. Without a national association, the coal industry could not speak its mind. In turn the government would be unable to deal with the industry if it were not for some such body.

Association Judged by Leader

In the public mind an organization is judged to a considerable extent by its president. This is particularly true when the body is composed of such scattered and diverse interests as those composing the National Coal Association.

Washington was quick to recognize in the selection of the new president a promise to accentuate more than ever the need of faithful dealing with the consumer. The Westmoreland Coal Co., of which Mr. Hutchinson is president, has a long and honorable record of service to its customers. It produces a coal of exceptional quality in the Irwin gas district and is the mainstay of many gas utilities in New England and in the Middle Atlantic States. The company frequently is cited by coal specialists in Washington as an example in pointing out the benefits of good performance on contracts. The type of business that Mr. Hutchinson represents in dealing with consumers always is ready to sacrifice any immediate advantage in the spot market and maintain its contract deliveries.

Valuing trade associations as it does, Washington may wish that Mr. Hutchinson were more versed in the details of association work. He comes from a district in which there is no local operators' association of the ordinary type. He long has been a director in the National Association, however, and has learned much of the detail of the National's business recently through his

duties as its treasurer. He has not, however, had that day-to-day contact with the statistical and traffic services of a vigorous local association such as those of Indiana and southern West Virginia. There is no reason to think, however, that he will look unsympathetically on the service functions of the National. One of the hopes most frequently expressed in connection with the change of administration has been that it would be marked by building up the National's bureau of coal economics and the traffic service to the point where it ought to be built.

On one phase of the association's interest Mr. Hutchinson brings definite experience. He is an authority on the problems of labor relations. It is true that the National is eschewed from direct dealing with labor matters, yet its course and its activities are so closely related to them that a president with such experience cannot but be in a better position to assume leadership.

Foe of Growing Union Power

Until a year ago Mr. Hutchinson was chairman of the League for Industrial Rights. This organization long has been associated in the public mind with that group of American employers who are seeking by legal means to check the power of trade unions. Mr. Hutchinson and the League not only believe that employers have a right to operate their plants without dealing with their men collectively but that it is feasible and expedient to do so. They believe that through legislation and through litigation it is possible to maintain the complete freedom and independence of the employer. Their experience has gone far to justify this belief. Mr. Hutchinson's own company and own district long have been non-union. Though the district was partly shut down by the 1922 strike, it emerged from that struggle without having surrendered any of the independence it seeks to retain.

The League has won some notable legal victories, one of which was the Danbury Hatters case, and another was the Bucks Stove & Range Co. case. It has been termed the liberal wing of the employers' movement. It is a storehouse and a clearing house for all information relating to the legal and constitutional phases of the labor problem. Mr. Hutchinson is clearly representative of the attitude of no compromise with the labor unions and a determination to exercise to the full the constitutional rights of employers. The public will see in his election the probability of a development of a labor policy in the National Coal Association. It also is admitted that his election will strengthen the belief that the associa-

Will Miners Take Up Polo And Mah Jong Next?

Frank Hodges, Civil Lord of the Admiralty in the British labor government and formerly secretary of the Miners' Federation of Great Britain, partnered by Evan Williams, president of the federation, defeated the Duke of York and his partner, Captain Basil Brooke, 2 and 1, in a foursome golf match at Ton Petre, South Wales, May 17. The match was the outcome of a challenge by Mr. Hodges at a dinner a year ago, which was immediately accepted by the Duke.

It was played on the miners' course of nine holes, which was laid out by the miners themselves on waste land. All of the contestants are members of the Council of the Industrial Welfare Society.

tion is getting away from its original determination not to deal with labor matters and is becoming more and more the spokesman of the non-union branch of the industry.

Says Vancouver Coal Reserve Has Been Overestimated

Coal mining on Vancouver Island was discussed recently by Charles Graham, mine manager of the Canadian Collieries (D), Ltd., before the Board of Trade of Vancouver, when he declared incidentally that the coal supply of the Vancouver district had been overestimated. Earlier surveys had placed the resources tentatively in the neighborhood of 4,733,000,000 tons of coal, while that made by the late Major J. D. Mackenzie shortly before his death two years ago, reduced this total to approximately 800,000,000 tons. While this is only an estimate over a large area, it is impossible to recover that tonnage, he said, while actual mining operations often proved that only a small percentage of an estimated tonnage could be produced.

In one mine at South Wellington only 10 per cent of the estimated tonnage had been recovered. By strange coincidence three out of four diamond drills sunk over an extensive area had struck small deposits. Subsequent mining operations proved the great bulk of the property to be absolutely barren of coal. Faults are frequent in Vancouver Island mines, necessitating considerable expenditures of an unproductive character to pass these in search of additional measures.

Mr. Graham declared that mining operations were conducted as economically as possible in all the Vancouver Island mines. Owing to the frequent faults and geological formations it often is impossible to mine by machinery. The increased use of fuel oil in Vancouver industries has caused a heavy marketing loss to the mines of the Island. At Cumberland the mines average only about three days' work each week. Other mines also are either working short time or are producing less coal than formerly, employing fewer men. Little if any development work is being undertaken, he declared.

Who's Who in the National

The following list of members and voting strength in the National Coal Association formed the roll call at the 1924 convention in Cincinnati, Ohio, May 14-16:

Wuxtry! Howat at Work!

Alexander Howat, once president of the Kansas district of the United Mine Workers, but two years ago booted out for not taking orders from Indianapolis, is at work with a pick. He has tried every other way to get back in the union and failed, so now he is riding out from Pittsburg, Kan., in his automobile and going down in a mine of the Debut Coal Co. while his application for membership in Local 5517 at Skidmore, Kan., awaits action.

All he has to do now is answer certain charges still held against him before the International board of the union. Then perhaps he will be back in again and can continue his rebellious actions against the Lewis administration from within instead of from without. Hearl Maxwell and James McIlwrath, former district board members, who were expelled with him, also have gone back to work, and August Dorchy, his former vice-president, and John Fleming, one time board member, will soon follow.

Railroads Speed Up Freight Movement in March

Freight cars were handled faster by class 1 railroads in March, 1924, than during any March on record, according to the Bureau of Railway Economics, the average daily movement per freight car for the month being 27.3 miles per day. This exceeded by 0.3 mile the average for March, 1923, and by 3.3 miles the average for March, 1920.

The average load per freight car in March was 26.6 tons, a decrease of 1.3 tons compared with March last year, and one and one-half tons under the average for the same month in 1920.

Freight traffic in March amounted to 36,420,962,000 net ton miles, a decrease of 2,800,772,000 net ton miles, or 7.1 per cent, compared with March, 1923. Compared with the same month in 1920, it was a decrease of 1,431,090,000 net ton miles, or 3.8 per cent. For the first three months this year, freight traffic amounted to 106,884,737,000 net ton miles, a decrease of 2.4 per cent from the corresponding period last year, when the greatest volume of traffic for any corresponding period on record was handled by the railroads.

Washington Hopes to Beat Last Year's Record

Coal production of the State of Washington for the first quarter, January, February and March, 1924, according to Wm. R. Reese, chief state mine inspector, was 794,504 short tons.

By maintaining this ratio of production for the balance of the year the industry will show an increase of production of nearly a quarter million tons over that of the previous year (1923).

Present indications are that this will be realized. Fuel oil in the California fields is at the peak, if not on the decline, and prices inclining upward, which must reflect on the coal industry advantageously.

Lumbering also is showing a decided slowing down, which will decrease the supply of hog fuel and other lumbering wastes now competing with our coal.

Imports from foreign countries are also on the decline compared with the past few years. In fact, the present outlook carries with it much encouragement for the coal producers of this state.

West Virginians Re-elect

The entire staff of officers for the West Virginia Coal Association, composed of the various associations of that state, was re-elected May 14 at Cincinnati in a meeting held during the National Coal Association convention. The officers are: President, J. G. Bradley of Dundon; vice-presidents, Everett Drennen, of Elkins, and G. H. Caperton, of Charleston; secretary, W. H. Cunningham, of Huntington; treasurer, C. C. Dickinson, of Charleston; assistant secretary, James E. Hart, of Huntington. The association urged the nomination of T. F. Farrell for director of the National from the smokeless field and Mr. Cunningham for director-at-large.

Coal Awaiting Transportation by Barge

These trains are lined up in one of the big railroad yards on the New Jersey side of the Hudson River opposite New York preparatory to dumping in barges for shipment to the metropolis.

Practical Pointers For Electrical And Mechanical Men

Permissible Equipment for Underground Coal Loading Machines

Mining Will Be Made Safer By Use of More Permissible Electric
Equipment — Loaders Must Not Endanger
Lives or Mines

CHARLES M. MEANS
Consulting Engineer,
Pittsburgh, Pa.

UNDERGROUND coal loading machines are destined in the very near future to come into general use in the production of coal. The application of loading machines will follow in the wake of undercutting machines and electric locomotives. Just what particular type of machine will survive cannot be determined. Neither is it possible to forecast mining methods that will best fit the changed system of loading.

Electricity has thoroughly established its adaptability for operating mechanical equipment of various kinds used in coal mining. When electricity was first introduced in mines, it

created a certain hazard because the sparks and open arcs will ignite gas or coal dust. However, increased knowledge of the behavior of electricity has made it possible to so design and operate equipment that this difficulty has practically disappeared insofar as mining machines and storage-battery locomotives are concerned.

Electrically operated mining machines of various types, storage-battery locomotives and certain other devices have been perfected so that they are

Loading Machines Must Be Safe from Fire and Explosion

The capital investment in a loading machine is high; therefore every provision must be made to keep it in operation as much as possible. It must also be safe so that all hazards of destruction will be practically eliminated.

An Old-Fashioned Way to Load Coal

The need of a mechanical loading machine probably came from such a suggestion as this. The demand grew from the desire to get the coal out quickly at low cost per ton.

now passed as permissible by the U. S. Bureau of Mines. Equipment so designed as to be passed as permissible does not mean that it is supposed to be operated where there is explosive gas or coal dust, but does mean that should such a condition be encountered the possibility of explosion is practically eliminated if the equipment has been properly maintained. It is now generally recognized that any device of this character used near the face of any mine where such conditions exist should be of the permissible type.

When we consider coal-loading machines we are dealing with a class of equipment that should be surrounded with all the safeguards that are used for other equipment under similar conditions. A loading machine is required to work close to the face where the actual conditions can only be determined from day to day if the work is advancing. If the actual mining is retreating, danger is also present due to roof disturbance and a possible liberation of a pocket of gas. Dust is usually in suspension and may be of such quantity and character as to be a serious hazard.

Before coal loading machines can be universally applied, they too must be fitted with permissible motors, controllers, wiring, etc., if a reasonable degree of freedom from accidents is to be obtained. Such electrical equipment has not been placed on the market as yet, but when a fair degree of standardization of loading machines has been attained it will no doubt be available. The development of permissible electrical equipment suitable for operating loading machines would be along fairly well standardized lines. With requirements clearly defined, no special problem will be involved in manufacture.

Until such a time as permissible equipment is made available for loading machines, their development will be retarded and their application limited to districts where explosive gas and dust is not likely to exist. As our mines get deeper the demand for permissible equipment will increase and the time will come in the not far distant future when all electrically operated mine equipment not used in intake air must be of the permissible type.

Electric Current Explained By Ventilation Analogy

As a rule technical writers employ the usual hydraulic analogy to explain the fundamental principles of the simple electrical circuit. However, as colliery electricians and others employed in mines usually have a knowledge of ventilation, an analogy comparing similarities between electricity and mine ventilation may be more helpful. But of course, analogies should always be carefully used, as they seldom prove correct if carried beyond certain limits. The hydraulic analogy serves its purpose up to a point, and that of ventilation may do the same, but beyond these limits, reference to either is unsafe.

Potential Like Water Gage

In order to force a current of air through an airway, it is necessary that a difference of pressure exist between the inlet and the outlet. In a similar sense it is also necessary to produce a difference of electrical potential or pressure between two points in an electric circuit so that a current may be transmitted from one point to another. Let us assume downcast and upcast shafts of a mine connected by an airway. At a point between the two shafts is a door which is closed. It should be distinctly understood, however, that references are made to conditions of pressure and current only. With a fan running and the door closed, there is a difference of pressure between the two sides of the door equal to the water-gage of the fan under the particular conditions, assuming that there is no leakage.

If the door is opened a current of air begins to circulate from the downcast shaft, through the airway, to the upcast shaft. There is no longer a difference of pressure between opposite sides of the doorway, but it is transferred between the top of the downcast and the inlet to the fan on the top of the upcast.

Further, it will be noticed that, whereas with the airdoor closed no difference of pressure existed between

points on either one side or the other, now there is a definite drop of pressure between any two points in the air course. This drop in pressure is caused by the resistance offered to the current of air by the surface of the airway, and the total of all the pressure-drops between all points is equal to the water-gage pressure forcing the current through the mine. Assuming the size of the airway to remain the same, an increase of pressure would cause an increase of air with a corresponding increase of pressure drop between points, the total of which must always equal the water-gage pressure at the inlet of the fan. This fact is important, as it has a striking parallel with relation to conditions in a simple electric circuit.

Current Increases with Airway

Again, if the airway is increased in section, while the pressure is assumed to remain constant, a larger volume of air will pass while the drop in pressure from point to point remains as before the airway was increased in section.

In these instances we have conditions typical of electric circuits. (A) If the water-gage pressure is increased for a given airway the volume of air will increase, as will also the pressure drop from point to point along the airway. (B) Resistance is offered to the air-current by the rubbing surface of the airway. If the pressure is kept constant, while the section of the airway is increased, the current will increase, and if the cross-section of the airway is reduced the current of air will also be reduced.

Referring now to an ordinary electric cell, let us assume a simple circuit connected to its terminals. The circuit is open by a piece of insulation so that no current can pass along the wire. The wire represents the airway, and the insulation takes the place of the door in the ventilation analogy. There is a certain difference of electrical pressure between the two points on either side of the insulator. The distribution of pressure in the electric circuit is similar to that when the air-door was closed: there is no difference of pressure between points on the wires connected to the same terminal of the cell, but the pressure between a point on one wire and another on the other wire is the same as that between opposite ends of the insulator.

Like Opening Door in Airway

If the insulator is removed and a continuous path is provided, a current will flow through the wire from one terminal to the other. This is equivalent to opening the air-door and allowing the difference of pressure to send an air-current through the airway, the fan acting like a huge cell from which the current is taken and returned. The assumption that a flow of current takes place in an electric current is justifiable, and that it also has direction is made evident from the fact that certain kinds of measuring instruments will read backwards or forwards, depending upon the direction of the current. It is very convenient to be able to refer to an electric current as flowing in a wire, because it assists the student to grasp more easily the theory of the subject.

Assuming the insulator to be re-

moved, it is now necessary to compare the simple electric circuit with the ventilating circuit, when the door in the airway is open. As soon as the insulator is removed, and the current starts to flow, the full difference of pressure between the two ends of the insulator vanishes and is transferred to the terminals of the cell, assuming this pressure remains constant.

This is just what happened when the air-door was opened. The full difference of pressure was transferred to the top of the two shafts. Further, the wire offers resistance to the passage of current, and consequently, a drop in pressure exists between any two consecutive points in the circuit. The total drop through the wire is equal to the difference of pressure necessary to force the current through the circuit. This is the pressure between the two terminals of the cell and corresponds to the difference of pressure between the tops of the ventilation shafts when a current of air was passing. An important point is that the current is not used in the circuit in the sense of being consumed. The amount returning to the negative terminal of the cell is the same as that which leaves the positive terminal, just as in the case of the airway, where the amount of air entering the downcast shaft is equal to that leaving the upcast.

Work Done Against Resistance

A definite amount of work is done in both cases, the one in overcoming the resistance offered to the air-current by the rubbing surface of the airway, and the other in forcing a current against the resistance of the wire. The drop in pressure from point to point in both represents work being done. Finally, we have the same two principles referred to regarding the airway: (A) If the pressure is increased for a given circuit, the current through the wire will also increase, as will the pressure-drop from point to point along the wire.

(B) Resistance is offered to the electric current by the wire. Assuming the pressure to be constant, if the cross-section of the wire is increased, a larger current will flow, and if the cross-section of wire is reduced the current flowing will be less. Hence, we see that the simple ventilating theory has much in common with the electric principles.

ENGINEER.

Lubrication of Locomotive Motor Bearings

High-grade oil should be used for lubricating the sleeve bearings of locomotive motors. The common practice is to use one or two gills of oil at each oiling period, which is on the average every seven days. The best results are obtained by pouring the oil into the separate oil-well chamber so that it must feed up through the waste to the axle. By this means dirt in the oil does not get to the bearings, the waste acting as a screen or filter. If the oil is poured on top of the waste, it will tend to flood the bearing and thus be wasted. It is not economy to try to operate with too little oil as any apparent saving is more than offset by the resultant short life of the bearings.

Production And the Market

Continued Excess of Consumption Over Output Hastens Inevitable Upturn in Soft-Coal Trade

The seeming anomaly of production at a level far below consumption and with demand and prices practically at rock bottom continues to prevail in the soft-coal markets of the country. Nevertheless, the long-deferred but inevitable upturn is slowly but surely approaching. A number of brave prophets in industrial affairs say that the present slowdown is only a breathing spell preparatory to a business revival in the autumn. Some irrepressible optimists profess even now to see the first faint gleams of sunlight through the dark clouds that have enshrouded the trade for many weeks. There is no question, however, that the trade is steadily settling toward a more stable basis, that a firm foundation is being laid for a revival—regardless of the forebodings of the incurable disciples of gloom. Meanwhile buying, such as it is, is largely of a hand-to-mouth character, even those whose stockpiles are no longer big showing no alacrity about entering into fuel contracts while there is the remotest possibility of prices going lower.

Shipping Board Bids as Market Indicator

The surplus of empty cars continues to swell steadily to a yawning void that fairly seems to ache for the initiation of the reported government scheme to set a summer coal-buying plan in motion. Shipments to tide-water as well as inland are at a low ebb and the demand for lake tonnage is markedly weak. Much light is thrown on market conditions by the bids submitted May 16 to the U. S. Shipping Board for supplying and delivering alongside vessels in New York Harbor 1,430 gross tons of bituminous coal running not less than 14,500 B.t.u. Four bids were received, the prices ranging from about \$1.92 to \$2.19 per net ton f.o.b. mine, compared with \$1.92 to \$2.77 in the bids submitted May 12 on 216,000 tons.

Coal Age Index of spot prices of bituminous coal

again failed to register any change during the last week, standing at 169 on May 19, the corresponding price being \$2.05.

Dumpings at Hampton Roads for all accounts during the week ended May 15 amounted to 261,732 net tons, as compared with 293,849 tons dumped during the preceding week. Coal dumped at Lake Erie ports during the week ended May 17, according to the Ore & Coal

Exchange, were as follows: Cargo, 523,499 net tons; fuel, 35,697 tons. The totals for the previous week were 450,570 tons of cargo coal and 32,726 tons of fuel coal.

For the first time since March the production of bituminous coal passed the 7,000,000-ton mark during the week ended May 10, when, according to the Geological Survey, the output was 7,121,000 net tons. This compares with 6,832,000 tons produced during the previous week. There also was a marked increase in the output of anthracite, 1,924,000 net tons having been produced, compared with 1,616,000 tons during the week ended May 3.

Despite the upturn in anthracite production, due largely to the settlement of local labor disturbances, the hard-coal market shows no diminution in strength.

Estimates of Production

(In Net Tons)

BITUMINOUS

	1923	1924

(a) Revised from last report. (b) Subject to revision. (c) Minus one day's production to equalize number of days in the two years.

Demand for the most-wanted sizes, particularly stove, is still greater than the supply, but the most pressing demands are being taken care of when the consumer is willing to take some of the less wanted sizes along with the popular favorites.

No Life in Midwest Yet

There has been practically no activity in the Chicago market during the last week. Domestic sizes, as heretofore, have been difficult to move and steam sizes have been in medium demand only. Mines running have been doing so very largely on railroad orders. Prices appear to be attractive enough to the purchasing agent; what is holding him back is a well defined uncertainty as to the future. On this low market it is surprising that there is not more price cutting, even on the better favored coals of the producing districts. The tendency to hold prices firm probably is a natural development arising from the large consolidation of coal properties already effected and to be effected a little later on in the season. It might be explained, too, by April balance sheets, now trickling into the front offices.

Eastern coals continue their inroads on the territory of the Illinois and Indiana mines. A substantial tonnage of

smokeless coal is moving into the Middle West and more is booked to move in later on. The demand for anthracite is reasonably good. Extra activity on eastern Kentucky coal is explained by the new and favorable freight rates recently published covering shipments from eastern Kentucky mines to points in Illinois, Iowa and Minnesota.

The past week has seen just a slight movement of domestic sizes from the Williamson and Franklin County field of Illinois. It is not an early storage movement, however; it is just a case of where unseasonable weather in two or three places cleaned out the dealers. In a general way there is no change. All mines have unbilled coal of all sizes on hand, excepting No. 2 nut and the smaller sized nut and screenings. No. 2 nut is unusually scarce throughout all fields and screenings are not plentiful. In most fields the mines are crushing mine run to make screenings.

The movement of domestic coal at St. Louis is practically at a standstill. Neither high nor low grade is being bought and wagonload steam is decidedly sluggish. It is expected that the storage of coal will begin in June this year. Country domestic is unusually quiet. There is a little country demand for steam sizes, but locally outside of the demand for screenings, which is good and which exceeds the supply, there is nothing out of the ordinary.

Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines

	1924			1923
	May 19	May 12	May 5	May 21
Index	169	169	169	221
Weighted average price	\$2.05	\$2.05	\$2.05	\$2.63

This diagram shows the relative, not the actual, prices on four-teen coals, representative of nearly 90 per cent of the bituminous output of the United States weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913-1918," published by the Geological Survey and the War Industries Board.

Kentucky Full of "No Bills"

Business continues generally quiet with the coal trade of Kentucky, neither the eastern nor western fields having much business in hand, while there is considerable unsold coal reported on tracks, at mines, at marketing points, and rolling, due to a general lack of orders. Cold weather over the week has resulted in just a few orders for small lots of coal, but retailers are cleaning up yard stocks and placing very little business. Utility, industrial and lake buying are all reported slow. Railroad consumption is a little below normal.

The general outlook for the next thirty to sixty days is poor, as competition is very keen, business is being done on very narrow margins, and the trade is anything but satisfactory. Prices are unchanged. The western Kentucky strike goes ahead uneventfully with the non-union mines producing more than enough to glut the market.

The movement of coal from West Virginia was greatly retarded for a few days by swollen streams throughout the state. All grades of smokeless are in a somewhat better market position. High volatile splint lump prices are a little weaker, but mine run is in a little better position than it was. As not much coal is being prepared, slack is becoming somewhat scarce.

Northwest Quiet Too

Duluth trade is very dull. Little coal of any kind is moving in. A slight spell of cold weather has been the only bright spot for the coal men. Prices still hold in both hard and soft, but some docks are being accused of cutting from 50c. to \$1 in order to obtain a few of the large contracts.

The trouble with hard coal is that it is expected that smokeless will go big here next winter, and the spread between hard and soft is so great that it is worth the consumer's while to buy smokeless. This is the frank opinion of coal men, and those who used smokeless this winter reported fine results.

Figures of coal on Head-of-the-Lakes docks at the first of the month show in all 2,900,000 tons of soft and 145,000 tons of hard. Of the soft, 1,700,000 is free coal. Shipments for this month will show a marked falling off from those of last month. The rate on lake coal from lower lake ports to Duluth has been set at 40c. a ton. This is 5c. below last year.

The coal trade at Milwaukee is very quiet. Naturally there is little demand for anthracite at this time of the year, but there should be a better movement of soft coal to industries. Jobbers who have canvassed the interior say there are no stocks of any consequence on hand, yet consumers continue to hold off. Coal keeps coming by lake in fair volume. Thus far this season the receipts of anthracite aggregate 68,576 tons and of soft coal 175,699 tons. The movement is bound to slacken when storage becomes a problem.

Western Trade Drags

There is little activity through the Southwestern district. A substantial surplus accumulated by independents during the shutdown of mines controlled by members of the Southwestern Interstate Coal Operators' Association is increasing. A few mines with small industrial contracts have resumed operations since the signing of the new agreement. The Western Coal & Mining Co. has reopened to supply the Missouri Pacific, but most operators are waiting for a market.

Kansas lump is \$4.50; nut, \$4; mine run \$3.50 and screenings, \$2.50. Arkansas semi-anthracite lump is \$6 and mine run \$3.25@3.50. No slack is available. Henryetta (Okla.) lump is \$5.50; nut, \$3.75; mine run \$3.50; and screenings, \$2.50.

In Colorado the coal market continues to drag. Industries are buying very little and the domestic consumption has fallen off considerably. Mines worked on an average of 22 hours per mine last week. Prices are unchanged.

Utah coal mines are working about two days a week. Mine-controlled retail agencies are stocking lump, but this total is small. Some of the operators are unable to supply the demand for slack, due to the light movement on the larger sizes. Prices remain firm. Operators declare they have reached bed rock. Whether dealers will offer storage rates this year has not been decided yet. Mine prices: lump, \$3.50; domestic lump, \$3; egg, \$2.50; nut, \$2.25; screen slack, \$2; slack, \$1.50.

Trade at Cincinnati on Even Keel

Lake business at Cincinnati is swinging back to its natural channel and business generally is beginning to run on a fairly even keel. Demand for steam coal is a little better, lending a steadying influence. Large sizes are a little firmer due to the pressure, perhaps that has been put upon the price of the resultant. There has been no change in the status of the specialized coals. In smokeless the firmness is all found in the lump and egg with production lagging a little behind demand. There is no change in the retail situation. The high water has interfered a bit with the bringing down of river coal and this even with a reduced tonnage because of the Kanawha shutdown.

While there are inquiries here and there for commercial tonnage, the steam trade at Columbus is dull. Consumers are content to buy in the open market, confident that low prices will continue for some time. Operators are not inclined to contract at present figures and outside of certain small renewals there is little doing in that line. Railroad contracts have been closed and the price for Hocking mine run is around \$2. The amount of distress coal on the local market is not as large as formerly, although a fair tonnage is being picked up by utilities and other large steam users. Prices continue irregular and weak and more mines in the Hocking Valley field are closing down. Domestic trade also is quiet. In the Lake trade quite a few vessels are moving from the lower lake ports to the head of navigation. Inquiries for lake tonnage are almost entirely lacking in marked contrast with previous seasons.

The market at Cleveland shows no revival from the lethargy that has prevailed of late. Production in the east-

ern Ohio No. 8 field in the week ending May 10 increased 41,000 tons over the preceding week. The total output was 280,000 tons, or about 40 per cent of potential capacity. Despite increased output, due to lake movement, slack prices hold firm at recent levels.

Line demand continues poor in the Pittsburgh market. No extended deliveries are being inquired for and producers find it useless to attempt to negotiate such business. The market is simply one of small spot lots, which are closely contested for, but with prices down to a low level there is no general declining tendency in prices. There are reports of some lake coal being loaded on track, awaiting sales. There are no regular negotiations on lake coal.

A slight improvement was noted during the week in market conditions in central Pennsylvania, production gaining a little over April. More orders are being booked than for a number of weeks, but these are going to operators with the lower production cost. The loadings for the week ending May 10 were 11,732 car loads, against 10,864 car loads for the previous week. For the period of May to the 10th, the loadings were 16,978 cars, against 14,133 in April to the same date. Prices show little fluctuation.

The trade at Buffalo continues featureless. Slack coal, which for a time was fairly strong, is now about in line with other sizes. Considerable West Virginia and Kentucky coal is selling here the price being cut to make up for the higher freight.

Dullness Again Enshrouds New England

The market for steam coals in New England continues extremely dull. Prices have not shown the firmness expected a fortnight ago, and in many directions there is an utter lack of buying interest. The staple industries, such as shoes and textiles, are in nowise improved, and reserve stocks are still large enough to preclude purchases of more than scattering amounts.

Navy Standard Pocahontas and New River are dragging along at \$4.35@4.60 per gross ton f.o.b. vessel, with no snap to demand. A fair amount of tonnage is moving coastwise on contract, but aside from certain commitments offshore there is little doing for spot shipment. On the whole the range of prices averages 5c. to 10c. less than a week ago, while coals of pool 2 grade have eased off 20c. to 25c.

On cars Boston, Providence, and Portland there is little change; \$5.50 per gross ton appears to be the ruling figure, but occasionally there are rumors of prices 10c. to 15c. less. Practically all the factors have maximum tonnages on their wharves, and some weeks there is an extra push to move coal.

All-rail trade is practically lifeless. Within the tidewater zone there is almost nothing doing via the rail route, and prospects continue decidedly dark.

Seaboard Markets Verge on Stagnation

New York consumers continue to buy on a hand to mouth basis, apparently unmindful of the future. There are some reports, however, that inquiries are increasing and that the present condition means a much stronger market within the next few months. Inactivity prevails at present, however. Demand is hardly heard of and buyers are hard to find. The New York tidewater market is on the verge of stagnation. Prices are maintained at their present level only because of the absence of coal on demurrage and the reluctance of operators to send coal to tidewater unless

it is on order and selling indications are good. Cars at the piers average 1,100 to 1,200 daily. Activity is lacking at Philadelphia, yet confidence is felt that the turn of the tide is not far off. Industrial activity has slowed down considerably as compared with a month ago, and even then there was much complaint of dullness. Many operators are devoting much time to reshaping the wage policy in an effort to get production costs down to meet competition with non-union mines. Spot prices are fairly stable. Tide shipments remain quiet, with very little coal moving outside of some bunkering. The number of cars at tide is small, as no one is taking any kind of a chance by having coal on demurrage.

Baltimore purchasers are merely buying sufficient to keep them in emergency supplies, but there is very little contracting and practically little storing against future needs. The only consolation in this is that when a demand develops, there will undoubtedly be a need for coal by practically all large users. The export movement has shown a disappointing falling off, though inquiry from Mediterranean and South American points would seem to indicate an early resumption.

The Birmingham market continues weak with inquiry and new business at a low ebb for steam coal, consumers picking up tonnage for immediate use in the spot market, with no inclination to stock. Contracting is slow. Practically all the remaining operators who did not make wage reductions last autumn or on April 1 last put new schedules in effect May 16.

Anthracite Market Retains Strength

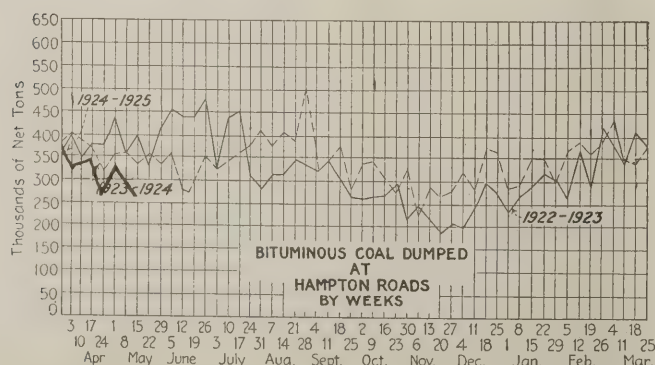

Anthracite demand at New York has not in any way decreased and consumers are just as anxious to have their bins filled as dealers are to fill them. Stove coal leads in strength. Some retail dealers refuse orders for this size alone, but will take orders when other sizes are included. Some quotations for straight independent stove are as high as \$9.75 at the mine, but when taken with other coals the quotations are about 25c. lower. There is plenty of egg and chestnut to be had. Pea coal continues in good demand, considering this market and the better grades of independent product bring full company circular. Consumption has been unusually heavy for this season because of weather conditions and dealers find themselves delivering small orders when they ought to be filling bins. Barley is the strongest of the steam coals with the better grades from independent operations bringing premiums. Buckwheat is easier, while rice maintains its strong position.

A strong demand for stove coal is a notable feature of the Philadelphia market. The situation from the producer's standpoint is better than at this time last month, but there are signs of an easing off. The yards are filling up with all sizes of coal, with most dealers having heavy stocks of nut. The opinion is general that the producing companies will add another 10c. to mine prices, but the thing that is giving the retail trade the most concern is whether their prices shall be advanced.

Output of beehive coke during the week ended May 10 was 177,000 net tons, according to the Geological Survey, compared with a production of 205,000 tons during the previous week.

Foreign Market And Export News

British Coal Market Stagnant; Miners' Wages Increased

The British coal markets are stagnant on account of the threatened strike of tipplers and trimmers, according to a radioletter to the Department of Commerce from Commercial Attaché Walter S. Tower, London, but a stoppage has been arrested by action of the Ministry of Labor. Prices are slightly firmer, reflecting the Ruhr labor trouble. The freight markets are dull and unchanged.

The recent findings of the official court of inquiry into the coal industry having been favorable to the miners, mine owners and union officials reached an agreement May 15 on higher pay.

The main point of the settlement is that the general minimum wage is to be increased from 20 per cent above the pre-war rate to 33½ per cent above. The standard of profits for owners is to be 15 per cent of the standard wage instead of 17 per cent as at present. The surplus, if any, is to be divided 88 per cent to the men and 12 per cent to the owners, instead of 83 and 17, as at present.

After the meeting A. J. Cook, general secretary of the Miners' Federation, said his Executive Committee would recommend that the men accept the agreement, though he was not satisfied it met with their full requirements.

Production by British collieries during the week ended May 3, a cable to *Coal Age* states, was 5,685,000 tons, according to the official reports. This compares with 4,049,000 tons in the week ended April 26.

Lethargy Grips Hampton Roads; Stocks Low; Prices Hold

Business at Hampton Roads is slow with foreign movement slumping and other lines of trade barely holding their own. The opening of lake shipments promised to boost coastwise trade, but little improvement has been shown. Stocks at the piers are lower than at any time in the year, and a state of

lethargy has settled down on the piers. Prices appear to hold their own, however, having reached what shippers term the rock bottom.

The tone of the market is dull. Contracts are absent, and general activity in the trade has reached a low level. Some of the dullness is attributed to seasonal conditions, and the trade is not exercised over the let-up in movement.

French Market Holds Its Own; Changes Are Insignificant

The situation in the French market is unchanged as far as French coals are concerned, except that production has declined somewhat. The demand for household fuel is practically at a standstill, consumers waiting for the summer rates before placing their orders.

With the sterling rate under 70 fr., British coals are offered at more reasonable prices. If the decline should continue, they may be within hailing distance in price to the French product and even cheaper than indemnity fuels.

Deliveries of indemnity fuels are averaging 42,700 tons daily, the total for April being estimated at 1,200,000 tons. Supplies of coke to the O.R.C.A. are at the rate of about 20,000 tons a day.

The M.I.C.U.M. agreement with the Ruhr operators was extended on April 15 to June 15, but may be terminated within that period if reparation payments are regulated before that date, according to a radio letter from Acting Commercial Attaché Donald L. Breed, Berlin. The main changes from the previous agreement include the fixing of the current coal tax at 1.50 gold marks per metric ton instead of 8 francs as previously, delivery of coal to the Régie at official German price minus 6 per cent and payment of overpaid taxes above \$15,000,000 on back coal taxes amounting to about \$2,000,000 of which \$1,000,000 is to be re-

turned at once. The current reparations coal deliveries amount to 1,650,000 tons monthly for which no payment is made, either by the Allies or by the German Government.

Ruhr Coal Output Near Normal

Coal output in the Ruhr during March is reported to have been 8,254,499 tons. This compares with 7,050,058 tons in February and 6,187,481 tons in January of this year, and 8,939,855 tons in March of 1913. Inasmuch as the output of three French "régie mines" is omitted in the figures for last March it is taken to mean that coal production in the Ruhr is now fully restored.

News Items From Field and Trade

ILLINOIS

Progress is being made on the new strip pit of the Equitable Coal & Coke Co., at Du Quoin. The H. H. Hall Construction Co., of East St. Louis, has completed the switch grade from the main line of the Illinois Central R.R. to the site of operations. It is expected that assembly of the huge electric stripping shovel will begin soon. Arthur F. Lee, chief engineer; T. S. Cousins, general superintendent, and Jas. McSherry, assistant superintendent, are the officials in charge of local operations for the company at Du Quoin.

The strip mine of the Hartshorn Coal & Mining Co., located near Elkhville, south of Du Quoin, is now operating full blast. The concern uses a 300-ton electric stripping shovel and all coal mined is put over picking tables and loading booms in a complete steel tippie.

The Jewel Coal & Mining Co., which is operated now by the Sterling-Midland Coal Co., of Chicago, is preparing to re-open its No. 2 shaft at Du Quoin. This mine has been closed for about two months. The company is moving a large coal-crushing machine from its No. 1 mine to No. 2, where it will be installed and put into use immediately. Mine No. 1 of the company has been closed and it is questioned if the mine will ever be opened again. Clarence Bean, formerly of Brazil, Ind., is now in charge of the company's affairs in Du Quoin.

All official business of the defunct Southern Gem Coal Corporation, formerly of Chicago, is now transacted at Pinckneyville, home town of Receiver W. S. Wilson. From the latest announcements, no further progress has been made in reaching a conclusive settlement for the creditors of the concern. Meanwhile, some 2,000 miners in Perry, Williamson and Franklin countries are still awaiting pay for December 1923.

The City of Moline has awarded a contract to the Moline Consumers Co. to furnish coal for the coming year at a maximum price of \$3.35 on Sherman 2-in. screenings and \$6.43 for pure seam 6-in. lump. Approximately 4,500 tons of coal will be used.

Assurance has finally been given that a complete and detailed survey will be made of the Big Muddy River regarding the possibilities of dredging it and making it navigable. According to Congressman E. E. Dennison, the Rivers and Harbors Committee of the House of Representatives recently reported a rivers and harbors omnibus bill which carries the survey as one of its items. The bill is expected to pass.

INDIANA

Contracts for the coal supply for the State of Indiana have been awarded by the State Purchasing Board. The Ogle Coal Co., Indianapolis, received a contract for 67,000 tons of mine-run deep-shaft coal on a bid of \$2.18 a ton f.o.b. mine. The same company got the contract for 20,100 tons of screenings at \$1.75 a ton. The Walter Bledsoe Coal Co., Terre Haute, was awarded contracts as follows: 12,000 tons of mine run, \$2.20; 24,900 tons of egg size, \$2.35; and 26,800 tons of screenings at \$1.75 a ton. The Bledsoe company's mine is close to the state farm and is able to ship with a low freight rate, which brought the total cost below that of competitors. Contracts for 10,000 tons for the State House and three other institutions are yet to be awarded.

W. H. Leland, of Chicago, president of the Leland Coal Co., closed a deal with Jabez Wooley, president of the Warwick Coal Co., for the Polk Patch mine near Boonville, for a consideration of \$500,000. The Leland company now owns nine mines in Indiana, Illinois and Kentucky. The Boonville mine will be opened at once as a strip mine, employing 60 men.

MASSACHUSETTS

The Island Creek Coal Co., in its report for the first quarter of 1924, showed net profits of \$998,231 after depreciation, depletion and federal taxes, equivalent after preferred dividends to \$7.76 a share earned on 118,802 outstanding shares of common stock, par \$1. This compares with \$738,276, or \$5.58 a share earned, in the corresponding period of 1923.

NORTH DAKOTA

Construction work on the new \$125,000 plant to be erected by the Lignite Coal & By-Products Corporation at Richardton, will begin soon, it has been announced by the company. Rev. P. Hoenerback, abbot of St. Mary's monastery at Richardton, is the president of the company.

OHIO

Ohio mines produced 40,726,215 tons of coal in 1923, according to a preliminary report by the division of labor statistics of the Ohio Industrial Commission. The report covers all of the coal-producing counties of the state and is a forerunner of a more complete report to be issued in a few weeks. Of the total output, 2,056,918 tons was pro-

duced by pick mining; 35,830,921 tons by machine mining and 2,878,376 by stripping. Belmont county, as in former years, was the largest producer with 13,272,618 tons by machine mining and 1,368 tons by stripping. Jefferson County was next with 5,239,582 tons by machine mining and 985,653 tons by stripping and Athens County is third with 4,403,932 tons by machine mining and none by stripping.

The Ohio Coal & Iron Co. recently increased its capital stock from \$50,000 to \$75,000, at a meeting at the offices of the company in Dayton. W. F. Grimes is president and E. H. Jaeger is secretary of the concern.

Col. Tom Morgan, former president of the Cincinnati Coal Exchange and until recently in charge of the jobbing department of the Webb Fuel Co., has been appointed by Clinton De Witt, president of the Chesapeake & Virginia Coal Co., as its Western manager. This was the position held by George W. Hill, Jr., until his death recently in Asheville, N. C. E. Makin Jones will be retained as his assistant.

A news item in these columns April 24 stated that the Pittsburgh & Bessemer Coal Co. had been appointed exclusive agent in Ohio and northern territory for the product of the Boone County Coal Corporation, of West Virginia. This was in part incorrect, for while the P. & B. company has been named as agent for the latter concern, it has not been made exclusive agent.

A meeting of idle miners in the Nelsonville section of the Hocking Valley was held at Nelsonville, Ohio, May 15 in protest against the operation of certain mines in that region on a co-operative basis. Most of the miners are out of work and are opposing their more fortunate neighbors who have organized co-operative concerns to operate a few of the smaller mines. The meeting was not called by the miners' officials and therefore did not represent the entire district.

PENNSYLVANIA

The Schuylkill County commissioners have decided to advertise the sale of Schuylkill County coal lands for non-payment of taxes. Ordinarily these advertisements are published only in the country newspapers, but the commissioners intend advertising these lands in New York, Philadelphia, Boston and Chicago papers. Attorneys for the coal companies say the proposed sale is a farce and predict there will be no bidders because the legality of the sale is questioned.

An outlaw strike, affecting all but one of the Lehigh Valley Coal Co. collieries in the Pittston region and throwing 11,200 mine workers idle, went into effect on Friday morning last. The strike order was issued by the general grievance committee. The cause for the strike was said to be the alleged refusal of Thomas Thomas, general manager of the company, to meet with International Board Member Alexander Campbell and District Board Member John Ruane, of the United Mine Workers, to adjust a strike of 800 men at the William A. colliery. Eleven collieries were idle because of the strike.

Harry M. Walker, who for the past eight years has been employed by H. M. Kanarr, mining engineer, Punxsutawney, has resigned his position and purchased the interests of Ned McCartney and will carry on a general engineering practice with headquarters in the offices formerly occupied by Mr. McCartney, rooms 9 and 10, Spirit Building, Punxsutawney.

The Lehigh Valley Coal Co. has established the position of efficiency expert in its mining organization and has assigned Sheldon Jones, formerly superintendent of the company's Lackawanna Division, to the post. He will make his headquarters at Wilkes-Barre. William Reutelhuber succeeds Mr. Jones as division superintendent.

Students taking the course in coal mining engineering at West Virginia University, numbering around twenty, will form a party which will visit the anthracite field during the second week in June. The students will see the mining and preparation of anthracite with all modern improvements used in its preparation. A detailed tour has been outlined which will include Hazleton, Wilkes-Barre, Scranton and Carbondale.

Directors of the Glen Alden Coal Co. on May 13 declared a dividend of \$3 a share on the capital stock of the company, payable June 20 to stockholders of record May 31. In December the company declared a dividend of \$2.50 a share, payable on the 20th of that month, while a year ago the company paid a \$2 dividend.

Edward Lloyd, Sr., 67, of Edwardsville, the oldest employee of the Kings-ton Coal Co. in point of service, has just retired after 57 years in the anthracite mines.

The Wyoming Valley Water Supply Co., which supplies the town and colliery at Centralia as well as the Mt. Carmel mines with water, has extensive improvements under way. The pumping house is being rebuilt and centrifugal pumps will replace the old plunger type.

Seward Button, former chief of the Department of Mines and part owner of the Beaver Valley Coal Co. operations in Scotch Valley, is negotiating for the purchase of the Tip Top Coal Co., controlled by Colonel Henwood, of Scranton. The mines practically adjoin the Beaver Valley colliery. The Henwood interests have been closed down for some time.

There were 151 fatal accidents in the industries of Pennsylvania during April, according to the Department of Labor and Industry Records. Of this total, 57 occurred in the mines. Schuylkill County led with twelve deaths and Lackawanna, also in the anthracite region, had nine. In the bituminous region, Westmoreland County led the list with six deaths, but Fayette and Washington each had five. Other mine fatalities occurred as follows: Anthracite—Luzerne, 5; Northumberland, 1; Carbon, 1; Dauphin, 1. Bituminous—Allegheny, 3; Cambria, 1; Clearfield, 1; Greene, 1; Indiana, 4; Jefferson, 1; Somerset, 1.

William Littlejohn

Elected president of the Rocky Mountain Coal Mining Institute at its last annual meeting. He was born in Scotland, emigrating to the United States in 1907. He became fireboss with the Utah Fuel Co. in 1910, and, after holding several other positions, became general superintendent of the Utah division of that company in 1919, which post he still occupies.

Incessant rains which caused all small streams in Cambria and Clearfield counties to overflow, have flooded many of the mines in the northern Cambria and Philipsburg regions. Approximately half the mines in the district are drift mines and most of these are flooded. Considerable damage will result.

State charters have been issued at Harrisburg to the following coal companies: Tip Top Coal Mining Co., Wilkes-Barre; capital stock, \$101,500; treasurer, Nat D. Stevens, 800 East Main street, Nanticoke; incorporators, Nat D. Stevens, L. M. Chapin, Brookline, Mass., and Philip V. Mattes, Scranton. Gledhill Coal Co., Lykens, \$15,000; treasurer, James H. Gledhill, Lykens; incorporators, James H. Gledhill and Mabel M. Gledhill, Lykens, and Raymond L. Filbert, Lebanon. Hazel Yough Coal Co., Pittsburgh, \$10,000; treasurer, Ralph D. McKee, Bellevue; incorporators, William H. McNaugher and Frederick E. Milligan, Pittsburgh, and Ralph D. McKee, Bellevue. Tunnel Hill Coal Co., Butler, \$30,000; treasurer, J. A. Roberts, 714 West Penn street, Butler; incorporators, A. F. Myers, 542

Mifflin street, Butler; J. A. Roberts, Butler, and Chester C. Martin, Slippery Rock.

VIRGINIA

The Virginia Smokeless Coal Co.'s office at Norfolk will be closed as of May 15, according to an announcement by its manager, T. M. Bailey. Mr. Bailey has resigned the presidency of the Hampton Roads Coal Club.

WASHINGTON

T. F. Kennedy, of Seattle, has been elected president of the Morton Coal & Coke Co., of Centralia, and J. M. Bell was made secretary at the recent stockholders' meeting. It is probable that the company's mine at Centralia will be operated on a lease instead of by the company.

Briquets from the new Amalgam Coal Co.'s Trent process plant now building in Spokane may be offered on the market as early as the middle of July. The plant, built on the unit system for future enlargement, is to be 166x30 ft. on the ground and will be capable of treating between 400 and 500 tons of coal a day. Washed coal from the Corbin mine of the Corbin Coal Co. Inc., in the Crow's Nest Pass field of British Columbia, will be used. George W. Evans is the engineer in charge of construction.

WEST VIRGINIA

The Roderfield Pocahontas Coal Co. has been organized to develop a 600-acre lease at the mouth of Spice Creek, near Roderfield. Officers of the new company are J. W. Strickler, of Welch, president and general manager; O. E. Linkous, of War, vice-president, and R. L. Page of Berwind, secretary-treasurer. This company is capitalized at \$150,000. There are four seams in the acreage, three of which are above water level, the coal ranging from 4½ to 6 ft. thick.

The Tompkins Fuel Co., of Charleston was organized May 5, the charter having been obtained by Harold F. Tompkins, Wm. G. Conley and Clyde B. Johnson, of Charleston; Roger W. Tompkins, of Cedar Grove, and Grant E. Tompkins, of Hughston. The company has taken over a mine at Cedar Grove operating in a 6-ft. seam of Kanawha Splint Coal and also has started work in the by-product mine on the property which has not yet been fully installed. Shaker screen tipples and picking tables will be installed at an early date and the mine will be electrified throughout, and modern machinery installed. The Tompkins interests own the land in fee.

Harold F. Tompkins of Charleston; Roger W. Tompkins, of Cedar Grove, and Grant E. Tompkins, of Hughston, who have been connected with the operation of mines in the Kanawha field for some time, have organized the Tompkins Fuel Co., capitalized at \$100,000. The company will take over a going mine at Cedar Grove, operating a 6 ft. seam of splint coal and also will open a byproduct plant. The property is owned in fee by the new company. It

is proposed to erect a tippie equipped with shaker screen and picking tables and also to electrify the mine throughout and equip it with the most modern machinery.

The Brady-Warner Coal Co. has put its Monon No. 1 mine, in the Monongalia County field, on an open-shop basis, with the 1917 wage scale in effect. Monon No. 1 mine is in the Pittsburgh vein. The new order does not affect the mine at the same place which taps the Sewickley vein, as that mine has not been operated for some time. The company also owns a mine at Osage, where both the Pittsburgh and the Sewickley seams are mined, but no announcement has been made with reference to the latter mines, which have been shut down since the first of the year.

The Elkhorn-Piney Coal Co. has closed its Huntington office and dispensed with the services of the entire force connected with the office there. This company owns mines in Raleigh and Logan counties, W. Va., and at Weeksbarrie, Ky. All mining superintendents in the future will report direct to D. T. MacLeod, vice-president in charge of operation at Milwaukee, Wis.

Development work is now under way on the Faraday tract, formerly the Frick holdings in McDowell County, W. Va., and Tazewell County, Va. The tract comprises about 30,000 acres. Under the direction of Col. James Elwood Jones, vice-president and general manager of the company, two plants are being installed on Dry Fork of Tug River, four miles above Hartwell. About 400 houses are under construction. The mines will be well equipped mechanically throughout so as to eliminate human labor as much as possible.

The Sardinia Coal Co., of Charleston, has been organized to operate on a small scale on Coal River. It is capitalized at \$25,000. Principally interested in the new company are Toney Mamca, Peter Mascele, Toney Dadola, Joe Piredda, John Morria, all of Olcott.

J. C. Pack, of Freeman, was recently elected president and general manager of the Smith Pocahontas Coal Co. Mr. Pack is well known in the Pocahontas and Winding Gulf districts having been connected for several years with the Iroquois Coal Mining Co., operating at Iroquois.

CANADA

The price of American anthracite in Montreal has been reduced from \$17 a ton to \$15.25. A fight for the Montreal market has begun between merchants handling Welsh and Scottish coal and those selling the United States product. It is stated that British interests will this year lay down 300,000 tons of coal, which is half of the city's supplies.

Excellent prospects for Canadian coal mining are foreseen by Charles Fergie, president of the Atlantic Coast Collieries, Ltd. His company recently acquired 17 square miles of coal fields on the west coast of Cape Breton.

The British Empire Steel Corporation is conducting extensive investigations with a view of improving the Sydney Mines coal field, instead of planning to close it out. All coal-mining operations have been curtailed for the present because of the limited demand. Because of the high cost of production the Jubilee mine is temporarily closed. Vice-president J. E. McLurg states that the only mining the corporation can at present do is for shipping, and by closing down the

Clearfield Bituminous Corporation Building, Indiana, Pa.

This company is building a new tippie at Sample Run, about eight miles from Indiana.

Jubilee the Princess and Florence collieries can be operated full time. A survey of the field has been ordered and extensive drilling operations will be begun shortly with a view to lowering the cost at the Jubilee and possibly opening new pits.

A report of the Dominion Bureau of Statistics for January just made public shows an output of coal in Canada of 1,490,000 tons, an increase of 16 per cent over the January average for the preceding five years. There was an increase of 330,000 tons in Alberta; 28,000 tons in British Columbia and 6,000 tons in New Brunswick, but a decrease of 150,000 tons in Nova Scotia and 3,000 tons in Saskatchewan. Imports of coal in January were 1,233,000 tons, a decrease of 343,000 tons compared with December and a decrease of 5 per cent over the five-year average for January.

The National Coal Co., Ltd., has been incorporated by B. E. Bull, James C. Shaw, John A. Shaw and others with a capital of \$50,000 and head office at Toronto.

Some of the smaller collieries of Pictou County, N. S., are obtaining electric power from the hydro-electric power development of Sheet Harbor 60 miles distant and anticipate a considerable decrease in operating costs. New collieries opening up will in future look to this source of power supply.

The Piron process of low-temperature coal distillation, for which big savings in fuel economy are promised, is now installed at the new furnaces of the Ford Motor Co. of Canada, Ltd., Walkerville, Ont. Completion of a 400-ton a day plant there has been made by the Piron Systems' engineers. They are also at work on an installation with an ultimate capacity of 12,000 tons daily, at the River Rouge plant of the Ford company, to be completed during the year. The Ford furnaces are the first commercial adaptation of the process.

Coal Service of Canada, Ltd., has been incorporated with a capital of \$300,000 and head office at Montreal, by Daniel P. Gillmor, Wallace R. Henry and Jean P. Cosselte.

McMaster Coal & Transportation Co., Ltd., of Montreal, capitalized at \$500,000 has recently been incorporated.

Anglo-American Fuel Supply Co., Ltd., of Toronto, has been incorporated with \$50,000 capital, by Roland O. Daly, Charles E. L. Babcock and Harold E. Manning.

Trade Literature

The Treatment of Boiler Feed Water for Highly Overloaded Boilers, David Henderson, of the Dravo-Doyle Co., Pittsburgh, Pa. Distributed by the H. S. B. W. Cochran Corp., Philadelphia, Pa. Pub. No. 1195. Pp. 8; 6x9 in.; illustrated. Contributory causes of priming and foaming are described, together with a statement outlining in what respect water treated at boiling point is best adapted for use in overloaded boilers.

The Osgood Co., Marion, Ohio, has issued the following four-page illustrated circulars: No. 237, covering the use of steam shovel equipment and highway construction; No. 242, the use of steam shovels for sewer and trench excavating work; No. 243 describing the use of steam shovels when converted to clamshell and dragline outfits.

Fumes Encountered in Mining Operations and in the Handling of Explosives, by J. Barab, Hercules Powder Co., Wilmington, Del. Pp. 38; 8x10 in. Copies of this book may be obtained by writing to the advertising department of the above company.

Fourth Standardization Bulletin, by the Standardization Division of the American Mining Congress, Washington, D. C. Pp. 328; 6x9 in.; tables. Proceedings of the fourth national standardization conference held in connection with the twenty-sixth annual convention of the American Mining Congress.

Condulets for Switch and Plug Receptacle Outlets, Crouse-Hinds Co., Syracuse, N. Y. Four-page folder No. 8, covering condulets for various uses.

Twenty-fifth and Twenty-sixth Annual Reports of the Bureau of Labor and Industrial Statistics of Virginia. Part I covers period from Oct. 1, 1921, to Sept. 30, 1922, and Part II from Oct. 1, 1922, to Sept. 30, 1923. Pp. 224; 6x9 in.; tables.

Frogs and Switches, Helmich Foundry-Machine Co., Fairmont, W. Va. Pp. 21; 5x8 in.; illustrated. Catalog No. 5. Describes standard spring split switch, riveted plate frog, switch connections and throws, standard split switch, light rail turnout, etc.

Analyses of Samples of Delivered Coal, by Ned H. Snyder, Bureau of Mines, Washington, D. C. Bulletin 230. Pp. 174; 6x9 in.; tables. Covers samples collected from July 1, 1915, to Jan. 1, 1922, and contains a chapter on Tidewater Pool Classifications.

Production and Briquetting of Carbonized Lignite, by E. J. Babcock and W. W. Odell, Bureau of Mines, Washington, D. C. Bulletin 221. Pp. 82; 6x9 in.; illustrated.

Walter A. Zelnicker Supply Co., St. Louis, Mo., two-page bulletin No. 315 covering locomotives, cars, rails, pilings and tanks.

Traffic News

Provides for Taking Control of Road from Coal Company

After a rehearing the Interstate Commerce Commission has issued a conditional finding that public convenience and necessity will require the construction and operation by the Jefferson & Southwestern of a railroad from Mr. Vernon to Nason, Ill., at which a coal mine is being developed, and for about three miles westerly to a connection with the C. B. & Q., if and when a valid arrangement has been made and approved by the commission under which the connecting railroads will be afforded an opportunity, at any time within five years, jointly or severally to assume control of the new railroad company by purchase of stock or by lease. On March 14, 1923, the commission denied the company a certificate, but with the approval of the Illinois Commerce Commission it has built the line from Mt. Vernon to Nason and is operating as an intrastate carrier.

Must Restore Allowance for Boarding Car Doors

By decision of the U. S. Supreme Court, May 5, dismissing an appeal for want of jurisdiction, the order of the Public Utilities Commission of Colorado directing the Denver & Salt Lake Railroad Co. to resume in its coal tariffs an allowance of 50c. per car to shippers who board the doors of box or stock cars loaded with coal will stand. The company discontinued the allowance and the Bear River Coal Co., the Hayden Bros. Coal Corporation and others appealed to the Public Utilities Commission, which directed that the allowance be continued. The State Supreme Court sustained the order and the railroad appealed to the U. S. Supreme Court. This court found no federal question involved. The evidence showed that in Colorado at times box or stock cars are supplied for coal shipments and that the shippers board the inside of the doors to protect the doors.

Obituary

William Quinn, long identified with the coal industry, died suddenly at Harrisburg, Pa., May 14. With Mrs. Quinn he was driving through to Philadelphia and was stricken with pneumonia. Mr. Quinn was 35 years of age and for several years was sales manager for the Winifrede Coal Co., Cincinnati. During the war he started the General Coal Co., at Huntington, W. Va., but due to heavy taxation by the government and a disastrous lawsuit, this went out of existence about three years ago. He then was identified with the Merrimac Fuel Co. but retired from it prior to its failure and was engaged in the tax-adjustment business at the time of his death.

J. C. Brooks, who because of his 360 lb. was known as "the biggest man in the coal trade," died on May 9 at Greenville, S. C., where he was located as sales agent for the Southern Coal & Coke Co. with selling headquarters in Cincinnati. The body was brought to his old home in Lexington, Ky., where the funeral was held on the 10th. E. C. Mahan, director of the National Coal Association and Nolan Mahan, of Cincinnati, attended the funeral.

James P. Hickey, of Springfield, Ill., died May 8 of heart disease, after one month's illness. He was 45 years old and in 1919, helped organize the Central Illinois Mining Co., of which he became president, and of the Pontiac Coal Mining Co. He also became president of the Prairie State Coal Co., which post he held at the time of his death. Before becoming identified with mining in Illinois he was a member of the sales organization of the Pittsburgh Coal Co.

William L. Kingman, at one time general coal agent of the New York Central R.R., died at his home at Yonkers, N. Y., May 8, in his 83d year. In the early 80's Mr. Kingman became divisional freight agent of that road at Rochester, but with the rapid expansion of the coal trade he was made general coal agent with headquarters in New York City. On his retirement from active service, in 1908, he was industrial agent for the Central.

Coming Meetings

International Railway Fuel Association. Sixteenth annual convention, May 26-29, Chicago, Ill. Secretary-Treasurer, J. B. Hutchinson, 600 Michigan Ave., Chicago, Ill.

The American Society of Mechanical Engineers. Spring meeting May 26-29, Cleveland, Ohio. Secretary, Calvin W. Rice, 29 West 39th St., New York City.

American Wholesale Coal Association. Annual convention, White Sulphur Springs, W. Va., June 3-4. Secretary, G. H. Merryweather, Chicago Temple Bldg., Chicago, Ill.

West Virginia Coal Mining Institute. Annual meeting June 3 and 4, Elkins, W. Va. Secretary, R. E. Sherwood, Box 1026, Charleston, W. Va.

The National Foreign Trade Convention. June 4-6, Boston, Mass. Secretary, O. K. Davis, 1 Hanover Square, New York City.

National Retail Coal Merchants' Association. Annual meeting, Hotel Virginian, Bluefield, W. Va., June 4-6. Secretary, Walter D. Rogers, Transportation Building, Washington, D. C.

Southwestern Interstate Coal Operators Association. Annual meeting June 10, Kansas City, Mo. General Commissioner, W. L. A. Johnson, Keith & Perry Bldg., Kansas City, Mo.

Illinois & Wisconsin Retail Coal Dealers Association. Annual meeting, June 10-12, Delavan, Wis. Secretary, I. L. Runyan, Great Northern Bldg., Chicago, Ill.

Illinois Mining Institute. Annual meeting, June 12-14 from St. Louis via boat down the river. Secretary, Martin Bolt, Springfield, Ill.

Midwest Retail Coal Association. St. Louis, Mo., June 17-18. Secretary F. A. Parker, St. Louis, Mo.

American Society for Testing Materials; annual meeting, Chalfonte Hotel, Atlantic City, N. J., June 23-27. Secretary, Edgar Marburg, University of Pennsylvania, Philadelphia, Pa.

American Institute of Electrical Engineers, annual convention, June 23-27, Edgewater Beach, Chicago, Ill. Secretary, F. L. Hutchinson, 29 West 39th St., New York City.

First International Management Congress, Prague, Czechoslovakia, July 21-24.

World Power Conference, Wembley, London, England, June 30-July 12. O. C. Merrill, Federal Power Commission, Washington, D. C.

New Equipment

Metal-Spray Gun Prevents All Corrosion

Originally conceived as a means of coating iron and steel with lead to provide protection against atmospheric corrosion, the Schoop metal coating process is now claimed to be perfected so that any of the commercial metals, either in wire or dust form, may be applied to nearly all materials.

It is rapidly becoming an important factor in several industries, and many are taking advantage of its possibilities. Coatings of molten metal may be attached to all or any part of a surface, regardless of its character, size, position or location. Coatings also may be applied to work either before or after fabrication and to any reasonable thickness desired, either for decoration, protection from corrosion and chemical action, for increasing dimension or weight, for altering shapes or for repairing defects in surfaces. Successive coatings of different metals, regardless of their melting temperatures, may readily be applied.

The gun shown in the illustration weighs 3½ lb., is connected to standard acetylene and oxygen cylinders and a supply of compressed air at 50 lb. pressure. In normal operation it consumes approximately 15 cu.ft. of acetylene per hour, 15 cu.ft. of oxygen per hour and 50 cu.ft. of air per min. Metal in the form of standard gage wire is automatically pulled from a reel into the rear of a gear case and fed uniformly and continuously at a rate of from 12 to 24 ft. per min. to the muzzle of the barrel, where it enters a continuous reducing flame zone developed from the gases and air. Here it is melted and blown at a velocity of about 3,000 ft. per sec. in a very fine spray onto the surface being coated.

The mechanism within the gear case consists of an air-driven turbine operating a wire-feeding and straightening device for leading the metal into the

Gun Applies Protective Metal Covering to Surfaces

This device makes its own ammunition from wire. It bombards the surface which is to be coated with minute particles of molten metal. It is especially adapted for shop or field use on any material regardless of its size, character, shape or position.

Nozzle of Metal Gun

The wire, W, is automatically fed into the reducing flame zone Z, at such a speed that the position of the end of the wire is stationary. G is the cone of fine metallic particles which are deposited by impact.

barrel. The wire remains cold and unaltered until it emerges from the muzzle, melting and undergoing transformation into spray at a point of $\frac{3}{4}$ in. from it.

The muzzle is held 3 to 4 in. from the surface to be coated. Its temperature is raised but slightly, making it possible to apply coatings to the most delicate objects.

The spray is essentially an air brush which applies molten metal. The Metals Coating Co. of America, 495 N. Third St. Philadelphia, Pa., are manufacturers of the equipment.

Tram Bucket Dumps Itself At Any Point Desired

Dumping refuse at a distant point from the coal tippie long ago became a serious problem with the Tierney Mining Co. of Stone, Ky. All the available space around the tippie had been filled and the nearest additional dumping ground was a hollow approximately 1,200 ft. away. The company last winter installed a new type of self-dumping bucket tramway made by the Roderick & Bascom Rope Co. which appears to have met all the demands.

The striking feature about the tramway is the provision for automatically dumping the 55-cu.ft., front-door discharge bucket. As shown in the illustration, this bucket is equipped with a set of reducing gears engaging, at one

Bucket for Dumping Mine Rock

At the Tierney Mining Co's plant near Stone, Ky., a two-bucket installation handles 40 tons an hour of mine refuse a distance of 1,150 ft.

end of the train, the shaft of one of the track wheels. The other end of the train, by a worm, operates a perpendicular threaded shaft. The revolution of this shaft moves a trip block up and down. At the outbound end of the bucket's travel this block pushes down the trip lever which opens the bucket door. When the bucket is made to travel in the opposite direction the trip block runs up the shaft again, permitting the bucket door to close and latch for the next load. This trip can be adjusted so that it discharges the bucket at any predetermined location.

According to General Manager G. C. Wood, of the Tierney Mining Co. this mechanical arrangement operates without causing a shock like that received by the bucket when it is tripped by a clamp on the rope. It makes it unnecessary for a man to make the perilous trip out in the bucket to adjust such a block or to re-track a bucket that has jarred off. With the front-door discharge the load in the bucket is released a little more gradually than with a drop bottom, thus reducing the recoil.

The Tierney installation is a two-bucket tramway operating at a speed of 600 ft. per minute and capable of handling 40 tons per hour. One man operates it from the loading point.

Improved Steel Stair Tread Prevents Dizziness

One of the greatest objections to the use of open-grating stair treads has been the fact that men walking down the stairs, especially if they are carrying a load, find it difficult to tell just where the edge of each tread is and in some cases become dizzy. Consequently, heretofore, many designing engineers who could use open-grating treads to great advantage have been forced to use the flat solid type.

To meet just such conditions, the Mitchell-Tappen Co., 15 John St., New York, have developed a tread which has a clearly defined nosing. With this new tread it is not necessary to paint the outer edge or adopt any other makeshift change. The edge is made up of a nosing bar which is bent backward under the edge at an angle of approximately 45 deg. The bending of this nosing bar in no manner tends to clog the openings in the tread as it sheds both dirt and water just as the body of the tread itself does. The effect of this improvement is to produce the appearance of a solid line sharply defining the outer edge of each tread, and therefore lessening the chance of confusion.

Open Grating Tread With Outer Edge Well Defined

To prevent the steps from causing dizziness and to locate definitely the edge of each stair tread, this new step has a wide sloping nose bar.

Cross-section of Tread

The outer bar is bent to an angle of 45 deg., thus defining the edge of the tread and at the same time permitting the use of open-grating design.

Coal-company engineers will find this new tread suitable for tipples, breakers and washeries, especially in buildings where material and water are likely to lie on the steps and make ascent or descent particularly dangerous.

Metal Cutting Torch

A new cutting tip designed by the Alexander Milburn Co., of Baltimore, Md., marks another advance in the development of the oxyacetylene apparatus.

This tip, according to the manufacturers, has all the advantages of standard tips and many other distinctive features highly desirable for metal cut-

New Gas-Cutting Nozzle

The renewable seat makes it an easy matter to equip the torch with a new tip. This new tip mixes the gases much more efficiently and shortens the time ordinarily required to make a cut.

ting. A better method for mixing the gases and preheating the cutting oxygen, as well as giving added velocity and penetration to the preheating and cutting tip are some of the advantages claimed for it. The tip is provided with a renewable seat which can be replaced at very low cost, making it unnecessary to remachine or throw away the whole outfit. Aside from this, the renewable seat facilitates cleaning and maintenance. It is possible to reface a standard tip in a high speed lathe, but frequently such a lathe is not available where the torch must be used. It is claimed that the savings in time, oxygen, and acetylene effected by this new tip are approximately 18 per cent of the former cost of operation.

When the Wrench Fell

A STORY has gone the rounds to the effect that an employee of Henry Ford was seeking a job and, being asked why he left his previous place, said he had been "fired." "You see," said he, "I had to perform operation No. 4,560 on every car as it passed. My stunt was to screw a nut on a bolt in the few seconds available. One morning my wrench slipped. I stooped down to pick it up and by the time I had reached it three hundred cars had passed. I had tied up the whole plant, and the foreman fired me."

With all its exaggeration, this story is illustrative of a division of labor such as makes every man dependent on his co-worker in an extremely intimate manner. Not all division of labor works in just that way. The prop cutter, for instance, cuts his timber in the winter and delivers the props for use in the summer. He hauls his load when the snow affords good sledding. He cuts and sleds his product when he has nothing else to do. If he takes a week's holiday the mine is not delayed. It may take six months to realize the effect of the delay and perhaps no inconvenience will be experienced even then.

Similarly, the roadman may be off a few days, without direct effect on the mine operation. But most of the men are so immediately dependent on other men's labors that an idle man is a source of inefficiency throughout the plant. If the machine cutter fails to cut, several loaders are idle, the motorman gets fewer cars to haul, the dumper less cars to dump, the picking-table man less coal to clean, the trimmer less railroad coal to load and trim, and efficiency is destroyed. In consequence, the company may find the cost of coal greatly increased.

Some adjustments may be made, but they are effected on the spur of the moment, and any arrangement made thus speedily usually is both unsatisfactory in operation and slow in execution. Storage of coal may help, but only in a degree, and in most cases no storage is provided. Uncertainty, discouragement and inefficiency destroy all morale. A man who does a poor day's work becomes indifferent and sets his gait to suit the lower output and becomes a relatively unproductive unit even when conditions favor maximum output.

This argument might be used to advocate the steady reporting for duty of every man employed whose health and home conditions permit, and undoubtedly much depends on the reliability of the workman. Present conditions favor such responsibility. But to emphasize that consideration is not the purpose of this editorial.

Equally important is it that the cutting machine shall cut its anticipated quota of coal, that the shot shall be successful and bring down the appropriate tonnage, that the roof shall not be allowed to fall and close a room, that the locomotive shall pull all the coal as soon as loaded, and that the tipples shall always be ready for effective operation, to mention only a few of the links in the chain of production.

Reliability in machines is one of the keys to steady and profitable operation and no mine can succeed that has any uncertainty in the operation of its equipment. Much mine disability never finds its way to reports of the U. S. Geological Survey but does find place, not yearly or weekly but daily and hourly, in cost sheets.

Consequently, machines should be kept in perfect order, if anything in the world can be labeled perfect. To assure this, mere repair will not serve. The repairman should be set to work at inspection. He must know that the mechanical equipment is always in good condition so that slow work and shutdowns may be avoided and every man may do what is expected of him. That is why inspection is displacing repair and the trouble finder is being superseded by the man who forestalls trouble by prompt inspection and early adjustment.

Graham Bright, at the Cincinnati convention, said that steel and electric railway men spent twice as much on inspection as on repair, for in that way the most important item in economical operation is assured. J. F. MacWilliams states that inspection has lightened the work of the repairman and the machine shop. His repairmen were being detailed to inspection duties. No one safely can neglect this moral. Most men are busy correcting what greater wisdom and intelligence would have foreseen and forestalled.

Is It Absurd?

DOWN in Louisiana, or rather extending from Louisiana into Texas, the Magnolia Gas Co., is building a 16-in. steel pipe line to transmit natural gas from Shreveport to Beaumont. When completed this line will be 210 miles long and will carry gas at high pressure. Autogenously welded joints between pipe lengths will assure that the line will be absolutely tight.

Aside from all interest in this undertaking engendered by the difficulties encountered and the means taken to surmount them, this pipe line may quite possibly hold a valuable suggestion for the coal industry. It has long been considered commercially feasible to coke coal in byproduct ovens only at or near centers of population or in the immediate proximity of industrial plants that furnish a ready market for the gas evolved.

May not large high-pressure transmission lines solve the difficulties, heretofore considered at least formidable if not even insurmountable, and permit coal to be coked in byproduct ovens at the mine mouth, the gas to be sold in some distant center of population, coke to be marketed as a high-grade domestic fuel, while the other byproducts which run a long gamut of usefulness be sold at prices which will largely defray the cost of the mining and coking processes?

Take the coal fields of southern Illinois as an example. These lie within about 100 miles of St. Louis and less than 300 miles as the crow flies from Chicago. Burned raw the coals of this region, except when fired in furnaces that are specially constructed, are unusually smoky. Although the smokeless combustion of these

coals is entirely possible, the furnaces employed are practicable only to the industrial user. The domestic consumer, on the other hand, who must content himself with the ordinary stove or house furnace cannot obviate the emission of smoke when burning these high-volatile fuels.

In view of the construction of such pipe lines as that now being built in the Southland, is it any violent stretch of the imagination, any absurd flight of fancy, to picture Chicago within a comparatively short time as a smokeless city, even though it has long been famed as the smokiest locality in the country with the possible exception of Pittsburgh.

The advantages of byproduct coke as a domestic fuel have only recently become known to the average user. Already, however, coke has become a somewhat formidable rival for anthracite and other so-called smokeless domestic fuels. Gas, on the other hand, has long been considered as a most convenient fuel for stationary heating appliances. Manufacturing both of these products from a natural material at best but ill adapted to perfect combustion, and simultaneously releasing a vast variety of useful byproducts ranging all the way from drugs to fertilizers and motor fuel, may at no remote date react not only to the financial advantage of the coal producer, but to the general benefit and convenience of the entire country.

Guiding the Public's Choice

IF YOU find you cannot readily meet a specification, try to have it changed. If you can meet it but don't find it profitable to do so use the same recipe. Of course, it is sometimes well to give the public that for which it clamors, but when the public is not justified in its clamor a little propaganda is excusable.

The anthracite operators found that the public wanted too much large coal. So much indeed that the companies could not sell their fine sizes. The operators tried with some success to give the public what it wanted. They eliminated much needless degradation. They put in chutes that could be kept continuously full. They introduced conveyors and spiral troughs. They arranged in transporting coal to bed lumps on finer coal so as to reduce breakage. They removed the preferable sizes and fine sizes when crushing the larger so that no coal of salable dimensions should be passed through the rolls.

Unfortunately, they still had too much fine coal, and then there were the mountains of undersize coal that had accumulated in the earlier years when no one could burn anything but coarse sizes.

Consequently, do what they would, they could not sell the fine sizes in sufficient volume. Did they fill the valleys with their fruitless lamentations? For a while, it must be confessed that is just what they did. At last, finding that their regrets were vain, they decided none too soon to educate the public to use fine coal. Realizing that those using anthracite for steam purposes were headed uncompromisingly, and with some show of justification, toward bituminous coal and oil, they sought to convert the domestic consumer.

They combined their efforts and started economy shows. Little may have been done to cause people to dispense with equipment already in use, but this, at least, has been accomplished: When new houses are built, or when new furnaces are installed in place of old and worn out equipment, many persons successfully have been induced to put in arrangements for burning

finer sizes. Just how much has been accomplished remains to be seen, but evidence points to the attempt being successful.

Let the Illinois operators take the hint. They may succeed in advancing the day when steam plants and locomotives, even domestic furnaces, will be equipped for burning small sizes and one of their difficulties will be at an end. Why do they not combine to speed that happy day? Why leave it to salesmen who see only the easier way and sell what the consumer is ready to buy, leaving the operator's problems unsolved? Meanwhile every effort should be made to reduce degradation from the face to the railroad car.

Closing Down Mines

WHEN for any reason it is necessary to close down a mine it is likely to prove profitable to do it thoroughly, suspending pumping and ventilation as well as operation. That will mean lifting track and removing wire wherever rising water may reach the one or the other. Pump rooms and underground substations may have to be vacated. Such a complete abandonment will not be safe if rising water might work havoc on neighboring mines.

It seems sometimes that operators are disposed to believe that a mine thus shut down will be greatly injured. But it is well to remember that the mine will never contain more than a certain quantity of water. By ceasing to pump, a back pressure will be placed on the water which will probably reach a certain height and then cease to rise. The water pressure will attain a balance, after which no more water will come in. Consequently the operator who pumps during a shutdown may pump more than the operator who leaves his pumping till resumption.

As for the mine itself it will be preserved rather than destroyed by flooding. It is remarkable how mines, flooded thirty or forty years ago, retain the condition in which they were left. Falls are few partly because the timber is preserved and partly because the water keeps the condition of the roof, as to moisture, constant; it does not become alternately wet and dry. The pressure of the water helps to sustain the drawslate. The mine is watersealed and deterioration ceases.

The only disadvantages are that reopening is slow, that the copper will be restrung with difficulty and may be injured in withdrawing, and there is an expense in withdrawing rail, copper and other equipment. A company which thus proclaims itself out of the market for an extended period may make its creditors nervous. It may be at a disadvantage in defending some action in court, for the creditors may be able to impress some judge or jury that such an action is prejudicial to their interests. But on the whole the total abandonment of a mine is not so harmful as it is generally feared and not as costly as a steady run of pumping and ventilating.

Care must be taken in reopening as gas may collect under pressure, and if it cannot escape by the return as the waters are lowered, it may spread into the intake with unfortunate results. The air in these pockets may be so mixed with carbon dioxide and nitrogen as to be unflammable but if it escapes into the air of the ventilated portion the carbon dioxide and nitrogen may become so diluted by good air that the firedamp will become flammable and an explosion result from an open lamp or an electric spark. However, precautions can be taken against such an untoward event.

Early Coal Stripping Full of Heartbreak—I

The Art Was "Born" at Danville, Ill., Where Hand Work Began in 1866 Followed by the "Land Dredge," Dragline, Shovel-Conveyor and Other Strange and Wondrous Things

BY GRANT HOLMES
Danville, Ill.

IT IS a far cry from today's 300-ton giant electric shovel stripping 60 ft. of cover from a coal seam, back to the primitive hand stripping of 1866 in Danville, Ill. But it is interesting to look back through those years, for modern practice in coal stripping was "born" in Danville, so to speak, and most of the developments that have led from the hand shovel to the 300-tonner have taken place right in Danville territory.

If your mind has any pictorial tendencies you can see the first coal stripping of history—a man shoveling a little rotten coal from an exposed and weathered bed into a wagon. As the coal seam was followed back into the hillside the job of removing the earth from it grew too heavy for the man. So he made a horse do the work with a slip scraper. Then came the wheeled scraper for heavier operations.

At about this stage, coal stripping started in the Danville region in 1866. Kirkland, Blankeney & Graves opened a little pit on Grape Creek. Then followed a few years of slow expansion in the business. Michael Kelley, in 1875 was the next outstanding stripper. He began in Hungry Hollow and in the next decade was the principal operator of the region, with both strip pits and underground operations.

When a man opened a team-and-scraper stripping, he expected to lose money in the summertime and make it back in the winter, as the surface could be stripped only when the ground was not frozen. The truth of the matter is, many lost money and few got it back.

The usual method of exposing the coal was in long pits; first an oblong section along one edge of the field was plowed up, and then the scrapers took off the loose dirt. The piece was plowed again. Thus by alternate plowing and scraping, the bed finally was reached; the overburden being piled in a long mound overlooking the pit. Teams and wagons hauled out the coal during the winter, and the next summer a new block parallel to that just taken out, was stripped, the waste being dumped into the abandoned cut.

Considering the enormous quantity of material to be removed from an acre of coal under 10 to 15 ft. of overburden, small wonder was it that men came to the conclusion that team-and-scraper stripping had no commercial value. Nevertheless, it is of interest that this method is still in use, though only for local coal.

Another firm engaged in this primitive method of stripping was that of J. N. Hodges and A. J. Armil,

who in 1876 and 1877 loaded a lot of coal near Pittsburg, Kansas. Mr. Hodges had been engaged in railroad-track laying and ballasting in Ohio, during the two years previous, and had used a steam shovel in this track work for loading gravel. After a short experience in coal-stripping with teams and scrapers Mr. Hodges and his partner decided that the steam shovel could do the work far better.

In 1877, an Ohio contracting company rented these two men an Otis steam shovel. Unfortunately there are no pictures or description of this machine available—the first machine on record at least in the bituminous-coal stripping business. However, we know that Mr. Otis invented the steam shovel in 1839, and was killed in trying to operate the first one made.

Concerning the work of this pioneer machine, Mr. Hodges says—"We oper-

ated this shovel for about one year very successfully when I sold my interest to engage in other business, but the shovel was operated for about three years when it was returned to the owners. We had land with from 8 ft. to 12 ft. overburden.

"This, with good management, could be handled profitably, but coal at this depth was limited and the boom of this shovel was too short to do deeper work and waste the overburden far enough away to uncover a pit of coal of sufficient width to be handled economically." He also says that this experience proved to him that a larger shovel would be successful, but the manufacturers told him that it was not practical to build such a shovel.

The second stripping outfit which has come to my notice was merely a furtherance of Mr. Hodges' idea. The Consolidated Coal Co. of St. Louis, Mo., extensive land owners, had a strip-coal area which lay in a river bottom, known as Missionfield, near Danville, Ill. Here, the overburden ran up to 35 ft., but in many places, was only 10 ft. to 15 ft. deep. The bed of coal was 6 ft. thick. Contrast this with the lightly buried seam stripped in Kansas by Hodges and Armil! However, the seam they stripped was only 3 ft. thick.

The first requirement to produce coal in the Missionfield was to find some one with sufficient nerve to attempt stripping by contract. Wright & Wallace of LaFayette, Ind., drainage contractors and dredgers, were induced to accept an "ironclad" agreement to uncover a given quantity of coal daily for the Consoli-

THIS IS AN EYE-WITNESS HISTORY

SINCE 1875 Grant Holmes, of Danville, has had his hand and mind on coal stripping. Half a century of it successively as mechanic, boss, operator, advisor to and rescuer of failing strip companies, and finally as an investor and director in many stripping companies in Illinois, Indiana, Kentucky, Ohio and Pennsylvania have given him a background in stripping such as few men have. Probably no one is as well qualified as he to tell the story of coal stripping from its beginnings. So this is his story, although he credits his old-time friend and fellow-stripper, the late Alec Swanberg, with much of the inspiration for it.

dated Co., under the supervision of J. L. Swanberg and their mining engineer, Louis Stockett.

As Hodges and Armil had found, steam shovels had not been developed to a size suitable for stripping economically, for there had been no call for shovels larger than those for railroad excavations, but because dipper dredges were called upon to dig in deep water, they had been developed for longer digging ranges. Being experienced dredgemen, Wright & Wallace relied on the size of the dredge to carry out this contract for stripping, and in 1885 they purchased from the Marion Steam Shovel Co. of Marion, Ohio, a dredge minus the hull.

PUT DREDGE ON WHEELS AND STRIP WITH IT

The owners erected this machine on a wood frame supported by wheels, and a dry-land dredge or stripping machine was the result. Wood was the construction material used throughout in this excavator, even on the boom which was 50 ft. long. A single-cylinder, vertical steam engine furnished power to hoist the $\frac{3}{4}$ -yd. dipper and to swing the boom. Speed and power as measured today were not virtues with this machine, as one small engine took care of all operations.

Four hundred cubic yards of overburden moved in a day was a great record. One should remember in connection with this "astounding" feat, that those were the good old days when mine labor worked ten hours for \$1.50. There was no means of propelling this dredge except by block and tackle; hence, moving the outfit was a slow process, especially on curves, as all wheels were fastened rigidly to the frame.

Because their shovel could dig forward only, a circular path of operation was adopted by Wright & Wallace, as the only means of keeping the machine constantly at work. The whole plan of operation resembled

a flat coil spring—each cut decreased the diameter of the island of unstripped coal around which the machine worked. At one point in each revolution of the field, the shovel left, as best it could, a gap in the waste banks for the haulage way.

The initial circle, or thorough-cut, surrounded about thirty acres, which was one-third of the entire field. Many months were occupied in making this and each succeeding circle, for, although the circumference grew smaller, the curves became sharper, and proportionately hard to turn. When the circles became small, jacks were used to skid the land dredge around the sharp corners.

The widest cut the shovel was able to make in this overburden was only about 20 ft. Limited dumping range prevented placing the wastebanks far enough away to keep the dirt from covering up the face of the coal, and because of this burial of the face, entry cutting was necessary before the miners could load out the coal, all of which was removed from each cut as fast as the strippers uncovered it. One can readily see that if a long time was occupied by the dredge shovel in completing each circle, the face of the coal around the "island" would be exposed to the weather the same length of time, resulting in a heavy percentage of rusty, rotten coal in the output.

The slowness of this shovel, the narrowness of the cut, and the annual flooding of the field by the neighboring river, induced the stripping contractors to place a second shovel in the mine in order to keep their agreement with the Consolidated Coal Co. A general enlargement of the first design, including a $1\frac{1}{4}$ -yd. dipper, characterized this second machine. Naturally, its plan of operation was the same. A short time later, a third stripping machine was purchased, having a $1\frac{1}{2}$ yd. dipper, a 65-ft. boom and two vertical steam

The Great Dry-Land Dredge, the Precursor but Hardly the Progenitor of the Modern Stripping Shovel

Though this machine was the second put into operation by Wright & Wallace, contractors, in the Missionfield at Danville, it was the same type as the first which started work in 1885. It had a 50-ft. boom and a $1\frac{1}{4}$ -yd. dipper both operated by a single-cylinder, vertical steam engine. The great, cumbersome machine rode on wheels fastened rigidly to the underframe. It was moved by block and tackle and could cut only in a wide circular path which determined the method of stripping. It took months to make one cut around a 30-acre tract.

Butler Bros. 1890 Dragline

Machines of this type, originally developed for trenching in Kansas, worked in pairs from the edge of the cut. One uncovered the coal and the other loaded it into railroad cars run directly into the pit. This latter was the first mechanical contrivance for loading stripped coal. The stripping draglines made parallel cuts about 20-ft. wide in the coal and of any length.

engines. Both the stripping and coal ends of the business had now assumed quite respectable proportions with the three dredges operating.

In about three years, however, a snag was struck which seemed to lead on to the many failures that occurred in after years. The coal miners struck in 1888, shutting down the producing part of the operations.

No arrangements had been made in the contract between the strippers and the coal company to take care of such a contingency, therefore, Wright & Wallace continued to operate their machines during the strike. The mine owners were powerless to stop them, and in time, affairs reached such a stage that each shovel had made a complete circle in its respective working. Starting on the next cut, the machines began to cover up the coal stripped on the preceding round. To stop the ruinous work, the coal company had to buy the dredges and the contract from the strippers.

The strikers and the coal men at last settled their difficulties, and work was again resumed. For two years the new owners operated the three machines, but at the end of that time they were greatly discouraged as no money had been made owing to heavy expense and the slow rate of stripping. Hard work had almost worn out the machines, which were not made to stand such strenuous digging, and about 1890, after many fruitless efforts at repairing, the dredges were abandoned.

BUTLER BROS. INSTALL DRAGLINE EXCAVATOR

In Kansas and Missouri, where gravel is scarce, but gumbo, a kind of stiff clay is plentiful, a process called ballast burning had developed. A trench about 8 ft. deep, 100 ft. wide and a quarter of a mile long, was dug in the mud bed. In this, alternate vertical layers of coal and clay were built and the coal was burned, thus baking the clay. Butler Bros., Englishmen, had draglines for doing the ditching in this process. They burned ballast for the Rock Island R.R.

The Consolidated Coal Co., having heard of these dragline machines and their excellent work, started an investigation to determine the adaptability of the drag-

line to stripping. This inquiry ended by Butler Bros. accepting the contract to complete the job of stripping the Consolidated property at Missionfield.

The year 1890 marked a new era in the stripping industry. Butler Bros.—Henry A. and William—started work in Missionfield with three draglines. Each machine was of different bucket capacity, $\frac{3}{4}$ yd., $\frac{1}{2}$ yd. and 1 yd. respectively.

HORIZONTAL BOOM WAS ABOUT 80 FT. LONG

These drag or scraper buckets were simply steel boxes with an open end which had teeth on the bottom edge. A cable, traveling through a sheave wheel on the top of the drag, was an adjustable trolley which not only raised or lowered the bucket, but also provided a guide for its travel. Ropes fastened to each end governed the forward and reverse motions. A fourth cable was a means to trip a latch which let the drag swing, open and down, to dump its load. These various cables were strung through a horizontal boom, some 80 ft. long.

Wire ropes suspended from a vertical frame or gantry held the lower boom in position. Two upright boilers supplied power for a two-cylinder engine geared to three drums. Clutches controlled the starting, stopping and speed of these drums, each of which governed a bucket cable. Gearing from the engine to the truck axles gave the machine self-propulsion in either direction.

Instead of being down in the pit, the drag line worked on top of a bank from one edge, the horizontal boom extending over the cut. When the engineer wished to dig, he either let the bucket run out half the length of the boom, on the incline formed by hoisting the trolley rope high in the air, or he pulled it out by means of the reversing cable. Releasing the trolley, he then "dropped" the bucket into the pit.

The bucket was dragged up the side of the bank on which the machine stood, until full of material. Picking up the load with the trolley, and letting it travel to the end of the boom, the engineer tripped the latch. This allowed the bucket to be dumped. Now, with the exception of pulling the drag half way back, the operation was ready to be repeated. The accuracy and speed

Loading Strip-Pit Coal

The Butler Bros. dragline was the first mechanical contrivance for loading stripped coal. All the draglines, whether for coal or overburden, operated buckets like the one in the illustration on cables from 80-ft. booms. The scraper buckets for removing overburden or loading coal were simply steel boxes with an open end which had teeth on the lower edge. The capacities of these boxes varied from $\frac{3}{4}$ yd. to 1 yd. By their aid skilled operators would load coal into cars at the rate of three buckets per minute.

attained by an experienced engineer was truly remarkable—three complete operations a minute was not unusual.

As the boom did not swing, the whole machine had to be moved frequently to keep the "scraper" supplied with digging material. This required much track laying of an expensive nature, because the soft ground let the machine sink down unless ties were laid as closely together as possible.

Dragline operations laid the coal open in rectangular cuts about 20 ft. wide and a quarter of a mile long. The length of the boom enabled the waste bank to be built far enough away from the coal face to prevent its burial. Entry driving was therefore unnecessary, the miners loading the coal from the "open face." When the end of the cut was reached, the machine was shifted back about 20 ft. from the edge of the bank. It then dug back to the opposite end of the pit, laying open a new strip of coal and depositing the spoil in the cut from which the coal had just been quarried. "Drag-lining" transformed the field into a series of parallel ridges.

The Butlers' machines were first placed at work in the upper bottom of Missionfield, where Wright & Wallace had also operated. The stripping was shallow in the center of this "bottom," and the overburden contained no hard material such as shale or soapstone, consequently the dragline operated with such ease and speed that the Consolidated Coal Co. soon was enjoying an output of over 1,000 tons of coal a day.

The available stripping in this section of the field did not last long, as a large part of the coal had been mined while Wright & Wallace were at work. Increased depth of overburden, the unlooked-for appearance of hard, blue shale above the coal, and a bad flood, forced Butler Bros. to move two of their excavators into what is known as lower Missionfield. The third machine was abandoned.

The overburden in the eastern end of this field was light, therefore, the dragline fairly made the dirt fly from about 40 acres of coal. Here, the machines were

operated in tandem—one stripping, the other loading coal into the railroad gondola cars which ran directly into the pit. This was the first machine coal mining.

However, in the center of the field, shale, soapstone and increased depth of overburden were encountered, retarding the progress of the machine greatly, and it became necessary to drill and blast the hard material so that the bucket could dig it. The profits decreased correspondingly, as Butler Bros.' contract with the coal company was to deliver the coal on board cars, at a certain price per ton. The mine workers became dissatisfied, and struck for an eight hour day and heavy increase in wages. These troubles stopped business, and brought about the abandonment of the first draglines.

Cement Gun Used for Rock Dusting Mines

RECENT experiments, says Dan Harrington, formerly of the Bureau of Mines, have been made in a New Mexico colliery with a cement gun stationed at the intake end of the main entry. It ejects a stream of dry shale dust into a strong ventilating current. The tests indicate that the shale dust was discharged at the rate of 1 ton per hour. The velocity of the air current in one test was 800 to 1,000 lin.ft. per minute at the intake and about 400 lin.ft. at a point 6,000 ft. distant. The dust cloud at this point was dense 25 minutes after the cement gun was started, and definite evidence of dust settlement was found as far as 9,000 ft. from the gun.

When the air current that passes through the entry being dusted is uniform, the quantity of deposited dust is necessarily greatest near the point where the dust is ejected. To obtain even distribution of dust through an entry, it would be necessary to shift the dusting machine from time to time. In an entry such as that described, of 98 sq.ft. cross section and 6,000 ft. long, to obtain a deposit of, say, 4 lb. per linear foot, at the rate of 1 ton (of 2,000 lb.) an hour, the mechanical distributor would have to operate for 12 hours.—Bulletin 225, Bureau of Mines.

Further Progress Made with Voice Transmission From Underground Workings to Surface

Are Wireless Tests Valuable When They Are Made Between the Mine and High-Powered Stations on the Surface?

Receiving and Sending from Locomotive

Propagation Affected by Earth Strata and Sheet Water—Experiments carried on from Mine Locomotive Successful

BY J. J. JAKOSKY
U. S. Bureau of Mines

RELATIVELY successful underground tests in wireless communication have been conducted in Illinois, Pennsylvania, Arizona, Utah, Idaho, Colorado, Michigan, Wyoming, Kentucky, New York, Connecticut, and in England, Germany, Italy and France. As a result, occasional press notices and illustrations have appeared in many papers. This may lead to the impression that radio communication in mines and tunnels is an established fact and that the method is comparatively simple. As a matter of fact, this is not so.

In practically all these tests the general procedure has been to take underground a receiving set of varying degrees of sensitivity and listen to broadcast music or speeches from high-power broadcasting stations. The results of these experiments are of real value and much interesting information is being obtained. Receiving stations have been placed on trains and communications received while they were passing through tunnels, tubes under rivers or subways. Other tests have been conducted in the Grand Canyon of the Colorado, in submerged submarines, in water wells and caissons, in the new tubes under the Hudson River, etc. Tests have been made in every conceivable part of a mining plant, from the carpeted offices of the officials to the mule barns underground.

TESTS DETERMINE TRANSMISSION FACTORS

These tests are of much interest and are useful when interpreted with reference to the conditions under which they are made, as for instance, in relation to the surface and sheet waters, the geology, mineralogy, and topography of the measures, the presence of metallic conductors, such as electric power and lighting circuits, compressed air and water piping, trolley wires, telephone lines, hoisting cables, headframes, etc.

Practically all these tests, however, have three com-

mon factors. First, reception is from broadcasting stations of a power very much greater than practical for underground sending sets. However, even one-way communication, that is, from the high-powered station on the surface to a receiving set in the mine, would be of value if the entombed miners who survive could be equipped with reliable receiving apparatus to allow them to tune in to some nearby station. The entombed men could be informed of the progress of the rescue parties and that information, though it afforded no physical aid, might prove to be a favorable psychological factor. In some cases even entombed men might be directed to parts of the mine where they could be reached by rescue parties.

NO SUCCESSFUL MINE-TO-SURFACE TESTS

Second, in most of the tests coming to the attention of the U. S. Bureau of Mines, there is no mention of successful transmission from within the mine to the surface. This transmission is of the greatest importance. If a reliable means of voice transference can be placed at the disposal of entombed men, they could inform rescue parties of their exact location, the number of men entombed and living, their names and designation number, and the condition of the air supply. Such information would greatly facilitate rescue operations.

Thirdly, in practically all tests conducted either by the Bureau of Mines or outside experimenters, the data obtained indicates that metallic conductors such as trolley wires, power and lighting circuits, car rails, compressed-air and water piping, hoisting cables, steel frame work, etc., are the controlling factors in underground communication. An early publication of the Bureau called attention to the influence of such conductors upon radio transmission, and later work has greatly emphasized the importance of this feature. Most experimenters have neglected to consider the effects of such metallic conductors or "carriers" for the high-frequency currents. In some tests, however, the apparatus, when moved to other locations within the

NOTE—Headpiece shows set connected to harp on trolley pole. Line-radio communication may be carried on while the locomotive is in operation. Very little interference resulted from sparking of the trolley wheel. All tube sockets were mounted on special cushions to minimize vibration.

mine where such conductors did not exist, gave entirely different results.

In practically every deep underground mine test it has been noted that reception is much better in one place than in another. When the apparatus is moved from one part of a room, into an adjacent working or to another entry on the same level, better signals may be received. In other cases after the change no radio communication can be received.

If the radio waves actually penetrated the earth for any appreciable distance, it does not seem probable that moving the apparatus a few feet would make such a great difference in the result. The effects of line-

present, its sheet distribution, and, to a somewhat less extent, on the type of ore or mineral.

Some formations, such as coal, shale, etc., are insulators when dry. The metals recovered from ores may be excellent conductors but such ores as they exist in the earth are not necessarily so. This is due to the fact that the metallic particles, if existing as such, are separated by the matrix which as a rule is a non-conductor. In most ores the metals do not exist as such but as chemical compounds, which must later be extracted by hydrometallurgical or pyrometallurgical processes.

Coal, which often contains as much as 95 per cent

Portable Mine Apparatus

This receiving set was connected to two short sections of mine rail and picked up signals from a line-radio transmitting set connected to the rails in another section of the mine. Oftentimes, good results can be obtained by connecting the receiving set to the rail and driving a peg in the ground.

radio or so-called "wired wireless" should be considered by experimenters when conducting such tests.

I do not intend to convey the impression that pure radio is the only system of communication. On the contrary, any reliable portable system of voice communication will be satisfactory. The point to be emphasized, however, in connection with such tests is that if line-radio played an important part in carrying the signals in or out of the mine when tests are conducted and while the mine is in good working order—and all trolley wires, power and lighting circuits, etc., are insulated from the ground and with no breaks in such metallic conductors—can the same system of communication be relied upon in cases of disaster? Fire, falls of rock and roof, explosions, mine flooding, etc., will not only ground the electrical circuits but also break the conductors in many places, causing changes in the electrical characteristics of the metallic carriers, which must all be taken into account.

So far, practically all data obtained from tests conducted by the Bureau indicate that the absorption of radio waves in penetrating the earth depends mainly upon the relative conductivity of the strata through which the waves are propagated. The conductivity of the earth depends largely upon the quantity of water

of carbon, is usually an excellent insulator. Practically none of the carbon in coal is existent in the green state but is present as a complex bituminous or pitch-like material, which acts as an insulator. Most of the eastern coals are of such close structure as to contain little free water or moisture. The "combined" water does not add to the electrical conductivity. Many seams, both horizontal and vertical, contain sheet waters and seepages between strata which prevent transmission of signals for any considerable distance. Other minerals such as hematite and certain sulphide ores are conductors even when dry.

In all cases, however, the conductivity of beds of ores and minerals is greatly increased by the presence of water. Mine waters containing relatively large quantities of dissolved salts are good electrolytes. Radio waves are greatly attenuated in penetrating such waters, and in horizontal, uniform strata with numerous sheet waters, only a short penetration of the radio waves may be expected. The thickness and number of such sheet-water formations limit the penetrating power of the radio signals.

Similar effects have been noted in numerous government tests conducted on submarine signalling. It has been found that even the comparatively high-powered

transmitting stations aboard battleships can not be relied upon for continuous communication with submarines when they have submerged to a depth approaching that of the average shallow coal mine in this country.

In mine tests conducted when receiving from surface stations, it has been found that the signal strength is not greatly affected at a short distance underground, but drops off rapidly as soon as a depth is reached approximating that of seepages and the sheet-water formations. This holds true, of course, when there are no metallic conductors present to act as carriers. In mines having electric light and power circuits, such conductors

tained indicated that the range is dependent almost entirely upon the type of conductors present, their electrical constants, etc. The transmitting range of this set in the average coal mine is only a few hundred feet when there are no conductors present, but may be several thousand feet when operating in the vicinity of power and lighting circuits, telephone lines or other metallic carriers.

In another series of tests similar effects were noted when using a loop aerial for transmission. It is not necessary that the metallic conductor be tuned or have a natural period the same as that of the wave. The

Bureau's Experimental Laboratory

This station has been licensed to use any wave length and power. From here the experimenters were kept in touch with all the portable field stations as they were moved about in the mine. Both code and voice transmitting equipment was used.

will carry the signals down from the surface—and often with but slight diminution in intensity.

The extent to which such conductors act as carriers for the high-frequency waves depends upon their electrical characteristics and the wave frequency. If the electrical circuits offer high resistances to the high-frequency currents, there will, of course, be a great loss in signal strength. However, the capacities of machine windings, parallel wiring, etc., are often of sufficient magnitude to offer a relatively low reactance bypass or shunt for the high frequencies.

In a series of recent tests a 10-watt telephone transmitting set was mounted upon an electric locomotive, and the outfit connected to the harp of the locomotive trolley pole. A portable receiving set, consisting of a detector and two steps of audio-frequency, was used on the surface and connected to a 50-ft. single-wire antenna. The mine was operated by a shaft about 400 ft. deep. There was no difficulty in picking up signals from the underground moving locomotive station as long as the receiving antenna was placed in the vicinity of any electrical conductor extending into the mine. The signals were picked up readily when the receiving antenna was near the trolley wires, power and lighting circuits, telephone lines, and hoisting cables, the relative magnitude of the signals from the different carriers being in the order named.

In a series of tests conducted to determine the transmission range underground, a portable 10-watt transmitter was mounted on a storage-battery locomotive. A short three-wire antenna mounted on the top of the locomotive was used for transmitting. The data ob-

wave is propagated or guided by such conductors which function "aperiodically."

The effects of line-radio are particularly noticeable when using a loop antenna for reception. In almost every case where the receiver is placed at a sufficient distance underground to be shielded, it has been found that the loop antenna, when near metallic carriers, functions best when placed in more than one direction regardless of the true direction of the transmitting station. Moving the set to another location in the vicinity often results in the loop pointing in a different direction. A study of near-by conductors shows the reasons for such changes in the directional properties of the loop. When using a capacity-type antenna, such as a wire stretched along the mine entry, this loss of directional properties as a rule cannot be noticed.

The variation in electrical characteristics of underground mine-power distributing systems indicates that certain optimum frequencies exist for each mine. The higher the frequency used the more efficient the radiation and the less loss in signal strength, when carrying across gaps due to metallic breaks, etc., in the conductors. On the other hand, the attenuation of the high frequencies when traveling along metallic conductors or directly through the earth is much greater than for the longer wave-lengths. The optimum frequency to be used in each case will depend upon the electrical constants of the underground metallic conductors, distances to be covered and type of communication desired.

It would, of course, be admirable if adequate provision could be made for the placing of mine communication rescue sets underground and have them ready for

Testing with Loop Aerial

Practically all metallic conductors have a tendency to warp the signals and destroy the directional properties of the loop. This portable set was used in many places in the mine to study the effects of water, pipes, rails and mine cars.

use in cases of emergency. However, the capital invested in idle equipment while waiting for something to happen offers a serious obstacle—especially as the real usefulness of the apparatus for rescue operations has not yet been determined.

A direct service for the apparatus must be found in the everyday operation of a mine. Because radio can operate effectively and efficiently when the radiated energy can be guided by metallic conductors, it may be possible to use a simple low-power portable line-radio set. The installation of a line-radio telephone set is simple, it being necessary only to lay a wire 25 to 50 ft. long on the ground or stretch it along the wall or roof and in a direction approximately parallel to carriers, or to couple the set directly to such conductors by the use of suitable capacities or inductances. As far as actual installation of apparatus is concerned, the line-radio is simpler and can be installed in shorter time than the present underground mine telephone with its connecting wires.

The line-radio apparatus itself, however, is more complicated than the present simple mine telephone. After the line-radio apparatus has been developed to the point where its use for mine communication can be safely recommended, its final adoption will depend upon the operating conditions prevailing in each mine. The line-radio apparatus alone will necessarily have a higher upkeep and maintenance expense, but to offset this will be, not only the almost total elimination of telephone line and wire maintenance, but also one less wire to be given space in the mine haulageways and entries. This holds true of course when the line-radio utilizes power or lighting circuits already in place.

It has been found that practically any conductor insulated sufficiently for the economic transmission of power or lighting current will act efficiently as a carrier for the high frequency current. The conductor acts in a double capacity, the high-frequency current being superimposed upon the low-frequency or direct-current power without any interference to the power supply and with only slight interference to the carrier-current communication if proper coupling and filtering systems are used. No interference to telephone circuits is noted

by superimposing the high-frequency carrier on the telephone line. Much recent experimental and commercial work on line-radio and carrier-current communications has established its feasibility.

If the apparatus can be made sufficiently practicable to be used as a mine communication apparatus, it will prove advantageous for the following reasons:

(1) Men would soon become acquainted with the operation and care of the apparatus. In case of a disaster such knowledge would be of far more value than any short course or training which might be given men for the operation of other rescue apparatus.

(2) Maintenance and inspection service will be justified for other reasons besides the purely humanitarian viewpoint of safety.

(3) Purchase of sets, maintenance and apparatus costs can be charged to operating rather than to safety—and there is always more money available for the former.

(4) Breaks in the metallic conductors do not completely stop communication, as with a break in the lines connecting the present mine telephones. Short breaks in the carriers such as opening of switches, etc., are not as a rule directly noticeable in operation. Severe disasters which might cause one or more breaks will not completely destroy the conductors, and communication could probably be established despite them.

A LITTLE VOLUME ON MINE VENTILATION.—To Thomas Bryson, a mining engineer and certificated colliery manager of the Mining College of Wigan, England, the industry is indebted for a book entitled "Theory and Practice of Mine Ventilation." It is a thoroughly practical publication and is especially strong on the subject of mine fans. The public is accustomed to books which lay emphasis on distribution of air; this book lays the right stress on the ventilator. It treats of main fans and boosters but does not fail to deal with the basic principles of air distribution and measurement. The book measures 4½x7½ in., has 255 pp. and is distributed in the United States by Longmans, Green & Co., 55 Fifth Ave., New York City, the price being \$3.

Using Rock Dust in Shotholes to Lessen Violence And Increase Lump Coal

Explosive Is Laid Loose in Shothole and Above It Cartridges of Rock Dust Are Placed—The Dust Is Compressed, Reducing the Violence of the Blast—Flame of the Shot Is Extinguished by Shower of Dust

BY J. H. HORLICK, JR.

A FEW expert blasters have long used "cushioned" blasting and its advantages have been rather widely recognized, if not practiced, by shotfirers. Dr. Alfred Stettbacher, of Zurich, Switzerland, has described* a special method of rock-dust stemming introduced into the coal mines of the Ruhr district of Germany since the war by which it is claimed that the percentage of lump coal has been increased as much as 50 per cent with a reduction in explosives' consumption of from 20 to 40 per cent.

The use of rock-dust stemming has been demonstrated by the experiments of the Hercules Powder Co. to increase the convenience and safety to such an extent that there seems to be no reason why this method, or some modification of it, should not be adopted generally.

Former methods of obtaining the cushioned effect by air-spacing have involved refinements in tamping the charge which are difficult to perform in actual practice. With rock dust as stemming, the maximum cushioned effect is obtained, and the tamping operation is even simpler than in present practice. The procedure, in brief, consists in placing one or more cartridges of finely-ground rock dust in the hole after the reduced explosives charge has been loaded. The explosives cartridges should not be slit or tamped, and the long cartridges of rock-dust stemming are merely shoved into the hole without tamping.

DUST STEMMING QUENCHES FLAME

It was found in the Ruhr mines that the explosion compresses the rock dust and wedges it tightly in the mouth of the hole so that none of the gases can escape until they have done their work in bringing down the coal. If, by any chance, a blownout shot occurs, the rock-dust stemming helps to quench the flame. It is, therefore, a safety precaution, whereas coal dust frequently used for stemming is a real danger, and clay, though not a menace, has no flame-quenching properties. The compression of the rock-dust stemming by forming a long pressure chamber provides a greater area against which the gases can expand. In the following tests slight modifications were made in the method described by Stettbacher.

On the test in an Illinois coal mine, the explosive used was black powder. Here the coal is undercut 6 ft. and the bottom holes drilled just above a blue band which occurs in the coal seam about 3 ft. from the bottom. Usually a high percentage of screenings is produced by shooting these bottom or "snubbing" holes. In the method generally followed, an average of 30 in. of "F" blasting powder is used and tamped solidly. On our test shots with the cushioned method the charge

was reduced to 20 in. of "C" blasting powder in cartridges of equal diameter to those used by the miners. After placing the 20 in. of powder in the hole without tamping it, cartridges of limestone dust about $\frac{1}{4}$ or $\frac{1}{2}$ in. less in diameter than the borehole were inserted. This gave an air space above the entire length of the stemming. There was also an air space of 2 in. left between the powder charge and the first cartridge of rock dust. The end of the last cartridge of stemming was mashed so that it fitted snugly in the collar of the hole. The shots made by this method with about one-third of the usual powder charge brought down the coal satisfactorily with appreciably less screenings than generally obtained.

LESS SMOKE AND WELL-SPREAD ROCK DUST

On other tests in the Pittsburgh, Pa., district, more complete records were kept. In Mine No. 1, the coal is approximately 5 ft. high with about 10 in. of slate above it. All of the coal is undercut and is blasted by two rib holes; shooting the tight rib first with 2½ to 3 cartridges of a permissible explosive 1¼x8 in. in diameter. The other butt shot is fired after the coal broken by the first one is removed. Ordinarily 2 to 2½ cartridges are used for the butt shots. The holes are 1½ in. diameter and 6 ft. deep; the portion not occupied by the charge is tamped with moist clay stemming. In the tests tabulated below the finely ground limestone stemming was placed in the hole in two cartridges.

Clark Patent Tubing, 1½ in. diameter, was used as a container for the dust and was cut to bring the end of the stemming 6 in. from the collar of the hole. The remainder of the hole was then firmly tamped with moist clay. After blasting with this method there was much less smoke than usual, and limestone dust was found distributed in the rooms, 50 ft. and more from the face.

At Mine No. 2 lump coal is not the principal consideration but it is important that all slate and other impurities occurring in a band of "bone" in the middle of the seam be separated from the coal. Any method

Table I—Test at Mine No. 1, Near Pittsburgh, Pa.*

Kind of Shot	No. of Cartridges Ordinarily Used	No. of Cartridges Used on Test	Remarks
Tight	2½	2½	Broken down in excellent lump coal
Butt	2	1½	Good shot and good lump coal
Butt	2½	1½	Good shot and good lump coal
Butt	2	1½	Seemed to be shot rather heavy, but it appeared to produce practically no slack
Tight	2½	2½	Excellent shot in all respects
Tight	2½	2½	Broke coal half way across room. All coal in large size with practically no slack
Tight	2½	2	Hole was rather low. Some top coal hung and remainder appeared overshot

*NOTE—Article entitled "Increasing Lump Coal Production by Cushioned Blasting" read before American Mining Congress. *The Explosives Engineer*, September, 1923.

*NOTE—A slow permissible explosive was used. The "spreading" effect, typical of black powder, was readily apparent.

that produces less pulverization of this slate helps materially in attaining good separation. Shotholes are 1½ in. in diameter. The usual practice here is to drill one cut-hole in the center and near the top of the seam (which is 6½ to 7 ft. high) and to load it with four cartridges of a 1½x8 in. permissible explosive. After removing the coal produced by this shot, a rib hole is fired with a charge of 2½ to 3 cartridges, and then a second rib hole containing 2½ cartridges. The total charge for a complete cut, therefore, usually is 9 to 9½ cartridges.

With the cushioned method, using rock-dust stemming the charges were reduced from 20 to 30 per cent and it was quite apparent to the mine officials that the slate was brought down in larger pieces. The explosives charge was placed in the back of the hole and cartridges of shale dust were placed in the hole to within 6 to 10 in. of the collar. Neither the charge nor the rock-dust stemming was tamped. The small space at the collar of the hole was firmly tamped with moist clay. The results of each shot are shown in Table II.

A slow permissible explosive was used. In shots Nos. 1, 2, 3, and 4, in which the charges ordinarily used were

tamped by the cushioned rock-dust method, the coal was badly shattered, showing the necessity for a reduced charge when using this method. On most of the shots a "spreading" effect similar to that produced by black powder was quite apparent. Each shot dispersed some shale dust in the room, a safety precaution in itself, and there was much less smoke at the face than usually remains after blasting. On the last ten shots, 1½ in. tubing was used to contain the rock-dust stemming; on the other shots the diameter of the tubing was 1¼ in.

The difficulty of comparing results obtained in one mine with those in another, because of the many variables which occur in Nature, is well known. But even though the tests described have not been on large tonnages and have not extended over long enough periods to make them absolutely conclusive, the better results obtained by the cushioned rock-dust method were obvious in each instance.

You may feel that the increased percentage of lump coal obtained on the tests I have described is the result of the reduced explosives charges and is to be expected no matter what the method of tamping. However, it was apparent to all the experienced men who witnessed the demonstrations that the improved results could not have been accomplished merely by using less powder; for when the quantity of explosives usually necessary to pull down the coal without any overloading, was tamped by the cushioned rock-dust method, the condition of the blasted coal clearly indicated an overload. The explosives' charges used in our tests were less than could be relied upon to pull the coal with non-compressible tamping.

It was also observed that with the cushioned rock-dust method, the desirable "spreading" effect heretofore considerable attainable only with black powder was obtained with permissible explosives; and black powder when cushioned with rock-dust gave better results than larger charges tamped in the usual manner.

Laws of Britain Regulate Handling of Lamp

British regulations dated July 10, 1913, require among other things that no person shall place a safety lamp on its bottom unless it is necessary to do so for the safe performance of any particular work or unless authorized by the manager. In all cases when the person is at work it shall be placed at least 2 ft. from the swing of the pick, hammer or other tool. Should any person find himself in the presence of inflammable gas he shall not throw away his lamp or attempt to blow it out, but shall shelter it, hold the lamp near the floor, avoid jerking it, and take it steadily into fresh air. If the gas fires in the lamp where he cannot take it into fresh air, he shall smother out the light or extinguish it in water. No person shall when trying or examining for the presence of gas with a safety lamp raise the lamp higher than may be necessary to allow the presence of gas to be detected.

Every person using a safety lamp shall examine the same externally and assure himself that it is locked and in good order before entering the mine, and shall from time to time while in the mine examine the lamp to see that it is in safe working order; and he shall, when he has completed his shift, return the lamp to the lamproom. If the lamp is injured while in his possession he shall at once carefully extinguish the light.

Table II—Test in Mine No. 2, Near Pittsburgh, Pa.

Number	Location of Hole	Distance from Rib in Inches	Distance from Roof in Inches	Depth of Hole in Inches	No. of Cartridges ordinarily Used.	No. of Cartridges Used in This Test	Inches Rock-Dust Stemming	Includes clay Stemming	Remarks
1	R Rib 1	13	12	70	2½	2½	44	6	Coal badly shattered.

18	L Rib 2	12	16	72	2	1½	..	6	Very good lump. Later reported that back was tight.
19	Center	72	4	3	..	4	Pulled coal well and produced good lump.
20	Center	72	4	3	..	6	Excellent results.
21	R Rib 1	18	18	72	2½	2	..	6	Results good.
22	Center	..	15	72	4	3	..	6	Broke clear to ribs in some places. Good lump coal.
23	R Rib 1	72	2	1½	..	6	Seemed to be a very tight shot. Results good.
24	L Rib 2	2	1½	Fairly tight. Broke well with good lump coal. Began using larger tamping shells.
25	Center	72	4	3	..	6	Results very good.
26	L Rib 1	72	2	1½	..	24	Pulled very well.
27	R Rib 2	72	2	1½	..	4	Pulled very well.
28	Centre	72	4	4	..	42	Material smashed too fine. Considerable fine bone was produced which will be extremely difficult to eliminate.
29	L Rib 1	72	2½	2	..	8	Pulled well and good lump produced.
30	Center	72	4	3	..	6	Seemed to be shot hard. Coal broken, but not too fine.
31	R Rib 1	2½	2	..	6	Appeared to be somewhat overshot
32	R Rib 2	3	2	..	4	Very heavy burden. Results good and good lump coal.
33	L Rib 1	3½	2½	Very heavy burden. Results as good as could be expected.

Mine Inspectors' Institute Advocates Legislation Requiring Closed Lights and Permissibles

Miners to Be Searched for Liquors, Matches, Etc.—Benwood Explosion Exhibits Danger of So-Called Non-Gaseous Mine—Electric Lights Declared Efficient—Inspectors Favor Air Chambers in Shotholes

BY ALPHONSE F. BROSKY
Assistant Editor, *Coal Age*
Pittsburgh, Pa.

THAT the time has arrived for a general and uniform amendment and addition to the mining laws of the United States was the unanimous conclusion of the Mine Inspectors' Institute at its meeting, May 14, 15 and 16. These sessions were held while the National Coal Association and the American Mining Congress busied themselves with their alternate sessions. The members met in the Hotel Sinton, in Cincinnati, Ohio. Chief among the resolutions of the institute was one advocating legislation prohibiting the use of open lights in all bituminous coal mines large enough to ship coal by rail or water and in all other mines which, in the judgment of the district state inspectors, should be equipped with electric cap lamps. In order that dangerous gases may be discovered when they accumulate, the resolution contained a recommendation that approved flame safety lamps, bearing the approval plate of the U. S. Bureau of Mines, be used, where necessary in conjunction with electric cap lamps.

The resolution also provides that the operator search or cause to be searched any person entering or about to enter any mine in order to prevent such person from taking or carrying therein any intoxicating liquors, matches, pipes, cigars, cigarettes, or any device for making lights or fire not authorized or approved.

The adoption of the clauses set forth in the above resolution met at first with some opposition. Inspector Flynn, Alabama, believes that open lights are safe in mines not classed as gaseous, providing certain other safety measures are taken, but his statement did not remain undisputed for long; Robert M. Lambie, chief of the Department of Mines of West Virginia, briefly recounted the causes which he and others believe caused the Benwood explosion. It was another case where a small accumulation of gas ignited by an open light caused the death of many men. Coal dust, of course, played an important part.

"The approved electric cap lamps must go into every mine of the country," said Frank Hillman, of Alabama, who was backed by Inspector Cunningham, of Somerset

County, Pennsylvania, and others in his contention; and after an extended argument in which all joined, it was agreed that the Institute should not be satisfied with a compromise.

Later in the week, on Thursday morning to be exact, Dr. J. J. Rutledge, chief of the Maryland Department of

Mines, read a paper on "Closed Lights in All Coal Mines." He said that the new and improved electric cap lamps give as much light as a carbide lamp and a much better light than the flame safety lamp. Where the electric cap lamps are being introduced no difficulty is being experienced. No one can say when a mine is gaseous or non-gaseous, which is reason enough that all mines should be considered gaseous. Gas may accumulate unexpectedly by the opening of a clay slip, breaking through to old workings, or by allowing a door to remain open that should be shut.

The efficiency of a miner is greatly increased by the

use of an electric cap lamp. One operator in a southwestern state reports that this equipment actually increases the efficiency of a worker by an amount equivalent to 50 minutes in an eight-hour shift.

A resolution was passed requiring the use of none other than permissible explosives for blasting coal in any bituminous mine and limiting the quantity allowed in any one hole to the specifications approved by the U. S. Bureau of Mines. Certified shotfirers shall be required to inspect, charge, tamp and electrically fire all shots, first having tested the place to be shot for gas by means of an approved flame safety lamp. It is the opinion of the Institute as expressed in a resolution that detonators should be handled by none other than shotfirers. Clay or other incombustible material should be required by law in the tamping of shot holes.

And here is a surprising announcement made by the Institute: "It is the consensus of opinion of this committee (standardization committee) that the use of air chambers in drill holes results in an improved grade of coal and in the more efficient use of explosives." No further reference is made to this method of shooting by which excellent results have been obtained, notably

MINE INSPECTORS DEMAND:

- Electric cap lamps in all mines
- Flame safety lamps where necessary
- Searching of all miners for liquors, pipes, cigars, cigarettes, etc.
- Exclusive use of permissible explosives
- Shotfirers to fire all shots electrically
- Detonators to be handled exclusively by shotfirers
- Depth of no solid shot shall exceed 4 ft.
- Haulageways and aircourses shall be rockdusted unless moisture content is raised to 30 per cent.
- Rock-dust barriers shall be installed at mouths of aircourses and entries
- Cutter bars must be sprayed
- Superintendents must be held equally responsible with foremen for any accidents that may occur.

in the experiments made in the Naomi mine of the Hillman Coal & Coke Co. and conducted by Research Fellow Nelson of the U. S. Bureau of Mines and the Carnegie Institute of Technology. The Institute concedes the greater efficiency of this method but does not openly and directly approve of it. It is my opinion that the time is near at hand when this method of shooting will be permitted by law in many states.

A resolution was passed relative to solid shooting. It reads: "Coal that is mined or sheared is not classed as solid shooting. No coal shall be shot off the solid where other methods are adaptable; no hole shall be drilled deeper than the shearing or mining, and where coal cannot be mined or sheared, the maximum depth of the shot shall not exceed 4 ft."

Mine inspectors all over the country are behind the movement to establish rock dusting as a standard practice in all bituminous mines. They feel that only by the adoption of this measure, not neglecting others equally important, will the number of deaths due to explosion be reduced to the lowest possible level. Though a few of the inspectors are not yet convinced that coal dust is an important agent in explosions sweeping every part of a mine, and some are not yet assured of the effectiveness of rock dust to check coal dust explosions, the majority voice their opinion as follows:

SHOULD ROCK DUST ROADWAYS UP TO ROOM NECKS

"All haulageways, aircourses and productive entries shall be rock-dusted from the mine opening to the room necks. Rock-dust barriers shall be installed at the mouths of all aircourses and productive entries. In addition to rock dusting on all entries and aircourses, water lines of sufficient size shall furnish water at sufficient pressure for wetting down coal dust that may rise and accumulate in and about the working faces. Whenever, by analysis, the dust on a roadway or aircourse shows a content of incombustible material lower than that determined as necessary to render the coal dust inert, the section in question shall be fenced off, or the mine closed, until sufficient inert material has been added to allow of safe operation.

"Those mines, in which rock dusting is not done in the manner described in the preceding paragraph shall be equipped with efficient sprinkling apparatus by means of which the moisture content of floor material shall be made 30 per cent of the volume, the consistency being made such that a handful of dust will compress in a closed hand to a compact mass. The prescribed degree of wetting applies to all parts of a mine."

The resolution relative to wetting, as outlined in the above paragraph, destroys the value of the resolution on rock dusting. Active exponents of rock dusting are not in sympathy with any such weakling and contradictory resolutions. The recommendation covering sprinkling was adopted only to satisfy those who are not sure as to the effectiveness of rock dust. No other meaning can be placed on this action.

Another resolution involving sprinkling—however, in this case a good one—requires that: "Coal-cutting and loading machines shall not be operated in bituminous mines unless water is applied in such manner as to prevent the raising of a cloud of fine dust while the machine is in operation. All motors used in such machines shall bear the approval plate of the U. S. Bureau of Mines."

Section 7 of the resolutions provides that "accumulated gas shall not be permitted to exist after discovery in any mine longer than may be necessary to remove the accumulation," and that the latter "shall not be removed in such a manner as to endanger the lives of the men in the mines."

Section 8 provides that "In order to insure an uninterrupted circulation of air throughout the mine workings, it is recommended that all aircourses be securely and amply timbered and kept free of obstructions. Non-flammable material shall be used in the construction of all permanent stoppings, overcasts and undercasts."

The committee borrowed from the English laws in formulating its ninth resolution which reads: "Superintendents shall be held equally responsible with mine foremen for the enforcement of safety in and about mines. All mine officials shall be required to pass an examination and possess a certificate of competency issued by the various state departments of mines."

Section 10 contains resolutions involving qualifications and tenure of office of state mine inspectors. It reads: "Since state mine inspectors are charged with the general protection of life and property in mining, it is recommended that they be men who possess experience, technical knowledge and character, and that they shall hold office free from political influence. Their competency shall be judged by a merit system. It is further recommended that such mine inspectors shall be at least thirty years of age and shall have had at least ten years of practical experience in coal mines."

The newly elected officers of the institute are James Dalrymple, chief, Department of Mines, Denver, Colo., president; Frank Hillman, safety engineer, Woodward Iron Co., Mulga, Ala., first vice-president; E. J. Hoey, state mine inspector, Christopher, Ill. second vice-president; William Boncer, mine inspector, department of labor and industry, Richmond, Va., third vice-president; G. B. Butterfield, general manager, the Associated Companies, Hartford, Conn., secretary; J. H. Griftner, chief inspector, the Associated Companies, Champaign, Ill., assistant secretary; J. J. Rutledge, chief mine engineer, Bureau of Mines, State of Maryland, Baltimore, Md., treasurer.

Right Kind of Rock Dust Is Harmless

Rock dust properly used in coal mines to prevent coal dust explosions is not a hazard to the health of the miners, according to Dr. R. R. Sayers, Chief Surgeon of the U. S. Bureau of Mines. It is true that dust produced in metal-mining operations is often the cause of minor's consumption, but this is because of the peculiar character of that kind of dust, according to Dr. Sayers. In drilling operations a dust is often produced that is very irritating to the lungs, and the continual breathing of this dusty air produces a bad effect. In coal mines, the rock dust used for limiting explosions does not remain in the air to be breathed, but settles on the sides and bottom of the workings. In addition, dust that is not irritating is used for this purpose. Limestone dust made from limestone that is free from silica is best for this purpose, but shale dust, clay dust, and other dust can be used. Dr. Sayers suggests that a mining company about to introduce rock dusting into its mine should submit a sample of the dust to the Bureau of Mines to be analyzed.

Problem of Fitting Loading Machine to Physical Conditions of Mine and Coal Seam

Discussion at Cincinnati Meeting—Selection of Machine to Meet Physical Conditions—What to Do When Rock Laminations Are Encountered—Does the Machine Break Up the Coal?

Selecting a Machine to Suit A Particular Mine

PROMISCUOUS choice of a loading machine without regard to the conditions under which it must be operated was unsparingly condemned by R. A. Walter, consulting engineer, New York City, in a short address before the session on "Correlation of Mechanical Loading with Haulage and Mining Systems" at the Cincinnati conference of the American Mining Congress.

At present several hundred coal loading machines are in daily use, more than half of which are operating successfully. Of the remainder, many could be made to operate more satisfactorily were suitable mining methods employed. Loss through purchase of those entirely unsuited to local conditions, could have been avoided if careful preliminary analysis had been made of the conditions.

No machine loader can be universally applied nor does any mine present conditions permitting the successful operation of all the loading devices of proved merit. Given a suitable mine environment these devices will function efficiently, and practically every mine presents conditions permitting the successful operation of at least one of them. The right machine in a mine will undoubtedly cut costs, but purchase of unsuitable equipment is a sheer waste of money.

WHERE FACTORS FAVOR SURVIVAL

There are certain factors at each mine which affect machine loader operation. Each loader in a varying degree possesses qualities which enable it to operate where one or several of these factors persist. Analysis of mine conditions and careful co-ordination with equipment will therefore eliminate much of the guesswork heretofore incidental to mechanical loading.

A study of the following list of some of the more common influencing factors will quickly indicate the reason for many mechanical loading failures and may show how they might have been avoided:

Old or New Mine	Haulage
Available capital	Drainage
Floor	Ventilation
Roof	Power
Coal:	Machinery
Pitch of Seam	Labor:
Height	Attitude
Structure	Supply
Preparation	Type
Mining:	Housing
System	Local Management
Laws	
Surface Protection	

These are only the most obvious fac-

tors. There are many more—some vitally important. All have a bearing upon successful operation. None may be ignored without lowering efficiency. To ignore some of them will cause absolute failure. Mechanical coal loading can of course be installed more economically and with less inconvenience at a new than at a going mine.

Some types of loading appliances can be adapted to a going mine at a cost well within the limits justified by the

working room between face and props, others but little. Some machines will load only up to some specified width of working face, and others will load any width but consume so large a proportion of time in moving as to impair their efficiency unless the face is at least a certain minimum number of feet wide.

There are almost as many different roof conditions as there are mines. Each requires different treatment with which the loading machine must co-

A Gathering and Loading Machine in Operation

Adoption of mechanical loading has been beset with many obstacles one of the chief of which was the ponderous size and large cost of the machines used. An expensive machine must be kept busy a large percentage of the time or the overhead eats up the profit. Most of the difficulties in the path of machine loading have now disappeared.

possible saving in operating costs. Others cannot be economically applied. Generally production can be increased far more economically by installing suitable mechanical loading than by increasing the hand-loading capacity.

A factor too frequently overlooked by those experimenting with loading equipment, is the floor or pavement. Examination of loading equipment quickly indicates that some machines cannot operate successfully on a soft bottom. A shelly floor presents an entirely different problem from one that is smooth and hard. Rolly or irregular bottom eliminates other machines.

The roof receives more attention but is seldom studied with sufficient care. Certain machines by their action make bad roof worse. Others practically make a bad roof almost good. Some machines advance more rapidly than others. Some require much space for

ordinate. Compulsory timbering to within a few feet of the face restricts selection but need not necessarily make machine loading impossible. A good roof permitting wide untimbered working face widens the possible choice but does not by itself indicate that every machine within this range will function satisfactorily.

Contrary to the general impression there are mechanical appliances which can be effectively applied to pitching seams. Manifestly these will change as the pitch of the seam varies. On some pitches within certain limitations of thickness none now developed will promote efficiency but in the majority of cases investigation will show that some one or various machines can be advantageously employed.

Floor and roof conditions may indicate equipment which is barred by the height of the seam. As the coal de-

creases in thickness the selection of suitable loading equipment becomes more limited but coal only 19 in. thick is being mined with mechanical aids.

Seam structure and coal preparation are closely interallied insofar as they effect mechanical loading. Presence of bands of impurities in the seam either restricts the choice of loading devices, lowers their efficiency, or calls for auxiliary cleaning equipment. Ordinarily the miner picks out these free impurities and throws them into the gob. Theoretically he loads only clean coal into the mine car. Perfection of separation so attained in practice is an important factor in machine selection.

Operating sufficiently rapidly to attain normal efficiency, some loading devices will not permit any but the most casual separation of impurities inside the mine. Others permit a better separation than is obtained with hand loading. In some instances coal and impurities can be loaded together with an appropriate machine loader the cleaning being accomplished at the tippie by suitable equipment. In others the cost of this cleaning will either offset the economies effected by mechanical loading, or the cleaning will be unsatisfactory and the coal prove unmarketable.

IMPORTANCE OF COAL FRACTURE

Another important factor to be considered is coal fracture. Coal breaks into lumps of various size. Some are slabs, others blocks, or the lumps may lack regular shape altogether. Each fracture presents its own loading problem and a machine which establishes a big tonnage record in one coal may fail entirely in another.

Market sizes and classifications, and the use for which the coal is intended all have a bearing on the machine to be used. In some instances there is no objection to shooting the coal into slack. In others it is important that the coal be blocky and slack be held at the minimum. Many machine failures can be traced to ignorance of their inability to load coal of a certain size. Much coal is shot only sufficiently heavily to crack it, after which in hand loading it is dug down with a pick and then loaded. Designers of mechanical loaders have spared neither thought nor effort to construct a machine which will first dig and then load such coal. Some attain creditable results, others are as yet in an experimental stage.

With some loading equipment efficient operation can be attained only if all the coal is removed, which brings into our problem a new factor—surface protection. Where it is necessary to hold the surface this frequently determines the mining system. In other instances the mining laws are the determining factor.

It is evident that both must be taken into consideration in planning a mining system. Then follows a further compromise between the system so evolved and that under which the loaders suited to seam conditions will best operate.

In a new mine the selection of suitable loading equipment and a mining system which will not conflict with laws, or interfere with surface protection is comparatively simple. In a going mine it is more difficult. In many

instances the mining system used eliminates from efficient operation all but a few loading machines. In others some machines will load coal rapidly and well, though the efficiency attained through rapid loading is more than counterbalanced through losses inherent to the system but which do not effect hand loading.

Though machine loading simplifies and contracts the haulage system a continuous car supply to the loading machine is a prerequisite for efficient and rapid loading. It is quite easy to supply cars to some loading appliances and difficult to supply them to others. Gage of track and height and size of mine car must not be overlooked for they influence machine design, clearances and speed of operation. Inability to supply mine cars to the machine loader indicates an inexcusable haulage condition and is not a legitimate reason for postponing a trial of mechanical loading.

Like haulage, drainage and ventilation are greatly simplified. The concentration of work attained with mechanical loading permits a reduction in volume of water and air handled per ton of coal mined. The reduction is enormous as machine loading requires only from one-third to one-sixth the working territory required by hand loading for equivalent tonnage. In some mines presenting particularly difficult drainage and ventilation these factors may be the determining influence in the matter of machine selection.

As loading machines replace human effort with mechanical energy it is only natural to think that additional power must be supplied. In practice this need not be done. Places are loaded out so rapidly and regularly that cutting machines operate far more continuously than with hand loading, making the flow of coal more regular. There is no such prolonged afternoon drag on power as is found in hand-loading mines where for several hours each day each cutting machine and locomotive is continually on the line with controller wide open. Peak loads are not so high. Power need not be distributed over so wide an area. Less copper is needed and the more regular power consumption will show a saving over hand loading.

PRESENT POWER PLANT ADEQUATE

In many mines where the power plant is the factor limiting production, certain loading devices will permit a decided tonnage increase without additional power plant. Before selecting loading equipment careful analysis should be made of its effect upon the power consumption of haulage and cutting auxiliaries for the power consumed by the loaders is but a comparatively insignificant part of the total power used.

At going mines auxiliary machinery may have properties which will go well with one type of loader, but be entirely inappropriate to others. This should be borne in mind and a careful analysis made to ascertain whether it is advisable to install loaders permitting its use, or to purchase other loaders and replace present auxiliary equipment with that more suitable to the type of loader selected.

Whether labor is receptive or antagonistic to machine loading has an important bearing. A shortage of labor indicates the desirability of mechanical loading. The type of labor available will limit, and may determine, the matter of machine loading and the selection of equipment.

At mines presenting conditions favorable to machine loading, where operators must furnish houses for their employees, properly selected loading equipment will obviate erection of houses for the labor which the machinery displaces. At a going mine it permits increased production without any increase in houses or in labor personnel.

One of the most important factors in determining the possibilities of mechanical loading is the attitude of the local management. Given reasonably good mine conditions and the sincere co-operation of the operating officials, mechanical loading is almost uniformly successful. Lacking this co-operation and with the best mining conditions failure is quite possible.

RAISES MINE TO FACTORY LEVEL

Mechanical coal loading places coal mines on a more efficient plane somewhat approximating that of factory operation. Through heretofore unprecedented concentration of labor it promotes safety and supervision and makes possible large reductions in operating costs. In return for these advantages it demands a higher grade of labor, better supervision and more thorough engineering.

Before installing any particular loader or loading device every influencing mine factor should be ascertained and analyzed. Next the characteristics of each available coal-loading device should be determined. A process of comparison and elimination will show which equipment may be expected to operate satisfactorily after which a mining method, suitable to equipment and coal seam, must be planned. Such a preliminary investigation may consume much time but only in this way lies any reasonable assurance of success.

What Shall We Do With the Refuse in the Coal

MANY mines are perched on hillsides and the tipples are located in narrow valleys occupied by streams, railroads and houses. Serious problems will be confronted, said Thomas F. Downing, Jr., general manager of the Logan County Coal Corporation, at the Cincinnati Conference, May 14, if the laminated impurities in the coal are loaded by loading machines and brought to the tippie to be removed at the picking table. Remembering that mines thus located on hillsides dump their coal quite frequently near the level of the seam and lower the coal to the tippie by rope-and-button conveyor, Mr. Downing, suggested that it would be possible and convenient to clean the coal before sending it down the hill. Then the coal could be dumped on the hillside where more space or at least more height is available.

Mr. Downing said also that if the small sizes of coal had to be washed because of indiscriminate loading by

machinery it might be necessary to spend 10c. to 30c. a ton to remove what had been mixed in with the coal by the loader. Again referring to the disposal of the waste after segregation Mr. Downing said that he knew of one mine where \$70,000 had been expended recently in the erection of a plant merely for the transference of slate.

He also referred to the difficulty of operating loading machines where posts must be set near the face in order to keep dirt out of the coal. In selecting a machine, one that will need the least room will in many cases be preferable. He added that he believed the mechanical loader was coming and even the oldest of those present would see the loader firmly established. We shall be willing before long, said he, to invest money in coal as liberally as is customary in France. He said he had seen one tippie in that country six times as large as he had ever seen in the United States.

In the discussion, D. J. Carroll, chief engineer of the Chicago, Wilmington & Franklin Coal Co., said that the loading machines of his company were working in new mines where mine run was the only coal shipped so he could say nothing as to sizes. The men at the picking tables are well able to take care of all the refuse in the coal that passes before them. The only lamination in the coal is 1½ in. of rock about 2 ft. above the floor. He believes, without having any figures to substantiate his statement, that the breakage was greater than with hand loading.

BREAKAGE NOT DUE TO LOADING

Mr. Downing said that in a case he had noted the breakage was not due to the loading itself but to the heavy blasting that was necessary to prepare the coal for loading. In one case the prepared sizes were reduced 30 per cent and the machine had to be taken out. David Ingle, president of the Ayrshire Coal Co., declared that he believed the machines did not break the coal up as much as the hand loaders. In a mine thus operated, he had no control over the shooting; in the mine that he had equipped with mechanical loaders he had such control. He said he did not have much impurity in his coal and that what there was gave him no more trouble than when the coal was loaded by hand.

J. F. Joy, of the Joy Machine Co., said that in some mines the percentage of slack was increased owing to heavier shooting. In other cases that percentage had decreased, particularly in the Indiana coal fields, which he thought might be favorably circumstanced for the use of mechanical loaders. One manufacturer is placing twenty-five loading machines a month in that state. Any one who had a mine that would not permit him to use a loader had better exchange it for one that would. Operators that are satisfied with loading machines are keeping quiet and those that were not, were quite willing to air their views. He had said that 200 machines had been installed. There were actually more than that number, for there were cases where they had been purchased inadvisedly. This was not always due to the conditions but sometimes to lack of co-operation, failure to study the problem and antago-

nism from the men operating the machine and delivering cars to it. Often the hand loaders got cars that should go to the machine. At other times judgment is not used in keeping out impurities. However, there are enough mines in the United States that can use machines for loading with advantage. The man who wishes to be a coal operator should get one of these mines.

Mr. Whaley, of the Myers-Whaley Co., said his loader had a smooth action and picked up the coal with a slow motion and with about the same drop as when loading by hand. The breakage, therefore, was no greater than in hand loading. The coal, moreover, need not be shot any more heavily than in hand work, for the shots should be no heavier than would roll out the coal. The machine could handle lumps larger than two men could lift.

It is necessary to shake the entire face and loosen it so that the machine can pull down the rest of the face without loss of time. Mr. Whaley did not believe that machine loading would drive any operators out of the mines, but he felt assured that the efficiency of the whole industry would be greatly increased.

A. P. Cameron said he had tried a modified type of the Whaley loader and some Joy machines which are doing excellent work. There are, however, conditions that no loading machine can meet. There are some fields that do not want small coal. The Westmoreland Coal Co. pays the miner only for lump coal. It has 300 men loading this lump. The small coal is kept down to 30 per cent. No loading machine could produce coal with such a small percentage of screenings. Time studies made of the work show that the miners at the mine load only one-third of the time they are in their places. The other two-thirds is consumed in doing work other than loading. Much as the Westmoreland Coal Co. is interested in loading machines it has not found any machine applicable to its conditions.

Machines That Will Drive One-Hundred Feet Daily

Carl Scholz discussed mechanical loaders for rapid entry driving. He said that operators were trying to outdo each other, each striving to get the largest mine in the world. Aside from this operators are seeking large tonnages so as to meet the interest on the large investment they are obliged to make. The higher the wage paid and the greater the interest to be met, the more important it is to develop the mine rapidly. Taxes never stop and the more coal produced the more output over which to distribute these taxes.

With this in mind and with a purpose of increasing safety Mr. Scholz began a study of entry driving. He found that every loading machine assisted in speeding the driving of entries. He had averaged 1,600 ft. per entry per month with two machines working in parallel headings. Conditions must be studied, for the conditions are not similar in any two mines. Mr. Scholz said he had good results with the Jeffrey heading machine. By working three shifts he had actually driven 100 ft. in 24 hours.

There are two types of entry drivers, and the McKinlay machine makes a third. The disadvantage of the Jeffrey machine is in its size. To use it the roof must be good, for it is not possible to timber closer to the face than 40 ft. The coal loaded must be clean and with the Jeffrey machine this can be attained. As it uses no explosives the coal is obtained in large sizes, being five times that obtained with hand loading, an advantage that cannot be overestimated. The elimination of explosives also assists in keeping a sound roof. Unfortunately in one of the mines where the large machine was used the roof was not sound. In consequence the machine had to be withdrawn.

Another big item with the Jeffrey machine is its cost. A machine can be purchased for \$25,000. It takes several months to build. In the Glen Rogers mine the machines had to be withdrawn because of the presence of gas. No machines now are being operated except Joy loaders and they are giving satisfactory results. This machine gives better coal with undercut faces than with overcut. Mr. Scholz added that the mine had no drawslate. In answer to an inquiry he said that longwall could not be successfully operated in this country. With coal selling at \$1.50 a ton the operator could not afford to pay 75c. for backfilling.

W. M. Drake read his paper on "How to Obtain Maximum Tonnage with Loading Machines" which appeared in the issue of May 8, pp. 689-694.

Ingle Describes Mine in Which He Loads by Machine

At the session of May 15 David Ingle, president of the Ayrshire Coal Co., addressed the meeting on "Room-and-Pillar Mining with Mechanical Loaders." Other details regarding his system of operation and conditions of working have appeared in the issue of *Coal Age*, Jan. 31, pp. 163-166. He said his loading-machine mine was in the No. 5 seam of southern Indiana which is 5 ft. thick. This seam has a rectangular cleavage and is quite open. Sometimes in shooting the coal, the gases from the powder will blow out at the back of the cut and at other times the coal falls in a mass after being undercut, thus making loading difficult.

The seam is clean, running 1 per cent sulphur and 6 per cent ash. Most of the impurities come from the roof, which is a grey shale and rather tender. In places 6 in. of this rock falls down with the coal when it is shot and this material has to be cleaned before loading. The mine has a cover of between 30 and 70 ft. It makes much water and this with a soft fire-clay bottom presents a condition of much difficulty.

The mine had been operated for some time and then closed. The room-and-pillar method had been used in this prior operation, and it was continued when the mine was reopened. The cars as loaded by the loading machine hold 3,200 lb. The machines were started in rooms already turned. They are driven on 30-ft. centers and only about 4 ft. to 8 ft. of pillar is left between rooms.

News Of the Industry

Unusual Situation in Coal Trade Brought About by Hoover's "Buy Now" Scheme

Commerce Secretary's Advice Not in Accord with Those Hoping for Runaway Market Prices—Shrinking Stockpiles Near Lowest Safe Point—Baffling Prospect Looms

BY PAUL WOOTON
Washington Correspondent of *Coal Age*

An unusual situation in the coal trade is revealed by the reaction to Secretary Hoover's advice to buy now. Many of the producers of coal are not at all enthusiastic about Mr. Hoover's message and wish that he had kept his mouth shut. The operators who hold this opinion believe they will be better off at the end of next winter if the consumers are allowed to go ahead, just as they are doing, and use up their stocks. This will mean that they will come rushing into the market next autumn, with the probability that the operators who can afford to wait will profit much more than if buying had been spread evenly over the summer.

A few consumers already have recognized that the hand they can play to greatest advantage is not to draw on stocks now but to continue buying their current requirements in the existing easy market and then use their stocks when prices go up in the autumn or winter. Much interest is being manifested in the result of Secretary Hoover's letter. The more generally held view is that most consumers will not be able to resist the temptation of coasting on their stocks. Some think, however, that the consumers have been convinced that storage is greatly in their interest and that buying will begin as soon as stocks have been reduced to forty or fifty million tons. The only figures on storage which are available at the moment are those covering railroad fuel. It is significant that between March 15 and April 15 nearly 1,000,000 tons was taken out of railroad storage.

Stockpiles Diminish Steadily

On April 1 the aggregate coal in storage was 65,000,000 tons. Consumption is thought to be running around 9,000,000 tons a week. Judging from the probable consumption in excess of production, stocks now are around the 50,000,000-ton mark, the figure usually regarded as supplying a safe margin of storage. Some insist that a reserve of 40,000,000 tons is ample. With 2,000,000 tons a week coming out of storage, only a few weeks more need elapse until the country's stockpiles will have reached that low figure.

While there can be little question that Secretary Hoover's advice is in the interest of the consumer and the transportation agencies, if followed it will have the effect of keeping alive many of the high-cost mines—an incidental result which Mr. Hoover must regret. On the other hand, if the country continues to go to the stockpile for its fuel, and the paralysis of April and May be extended for four months more, the credit of all but the stronger companies will have been broken.

The consumer who holds on to a reasonable reserve apparently has no chance to lose. Coal is almost certain to increase in price next autumn. The difference between that increased price and the current price is almost certain to be more than the carrying cost on the coal in storage. If the coal in storage has cost, including transportation, \$6 per ton, the interest charges for six months would be 18c. a ton, an amount certain to be exceeded if there be even a slight car shortage.

To anyone passing around among the coal specialists and others who are watching the market it is apparent that they sense something puzzling and baffling in the present situation. Somehow coal has entered on new times. The situation is more difficult of analysis than in the past.

No one ventures to predict what the ultimate results of the three-year wage agreement will be. No one will even hazard a guess as to how much of the market usually considered as belonging to the union fields will have passed into the control of the non-union producers. No one will attempt to answer what is to become of the mines that are being shut down. Are they to be allowed to cave in and be abandoned? What is to become of constantly growing surplus of union labor? All the union operators now have attached their signatures to the three-year agreement. Competition grows in intensity with each passing week. Major forces are at work on the far-flung coal industry, but even those possessed of unusual vision are frank in the admission of their inability to answer the questions which are on many lips.

No Cut While Contract Runs, Says Lewis

John L. Lewis, International president of the United Mine Workers, declared May 20, at the biennial convention of the Illinois district union, at Peoria, that coal operators who were predicting the necessity of modifying the miners' three-year wage contract, were mistaken. "There will be no modification of that scale now or at any time until the term expires," he said.

"Lower wages would not bring more work," President Lewis said, "and there is no hope for immediate relief. Depression in the industry will continue until the enormous reserves piled up against a possible strike are exhausted. Those reserves approximated 75,000,000 tons.

"They are burning up that reserve now, and no difference what rate we have as long as the reserve continues, people will not burn more coal than they require. If we had taken a \$5 rate (a reduction from \$7.50) at Jacksonville, non-union rates would have gone still lower, and present conditions continued."

Shipping Board Opens More Bids at New York

Bids were opened last week by the U. S. Shipping Board at New York for furnishing and delivering alongside vessels operated by the Board from New York harbor two separate lots of bituminous coal with a minimum 14,500 B.t.u.

The first batch of bids, opened on May 19, called for 1,500 gross tons of coal. The bidders and prices were: Seiler Coal Co., \$5.48; H. B. W. Haff, \$5.31; Imperial Coal Corporation, \$5.42; Willard, Sutherland & Co., \$5.68; E. Russell Norton, \$5.49; W. A. Marshall & Co., \$5.85, and Steamship Fuel Co., \$5.09.

On May 23 the following bids were received for furnishing and delivering 5,000 gross tons of coal. Steamship Fuel Co., \$5.19; Seiler Coal Co., \$5.13; H. B. W. Haff, \$5.41; Coleman & Co., \$5.51; E. Russell Norton, \$5.61, and W. A. Marshall & Co., \$5.90.

Announcement has been made that the bids received on May 12 for furnishing the board with a maximum of 18,000 gross tons monthly for one year have been rejected and new proposals will be received on June 2.

Keen Competition Marks Bidding for Supplying Navy with Coal

Bids opened by the Navy Department May 22 for supplying 768,600 gross tons of coal for the use of ships and shore stations during the fiscal year beginning July 1, next, showed unusually keen competition, nearly one hundred companies submitting quotations. The department probably will award contracts this week.

Tenders were asked on 330,000 tons of steaming coal for ships and 538,600 tons of bituminous or semi-bituminous run of mine for navy yards and shore stations, practically every item being competed for by a number of firms. Following are the bids submitted on the more important items.

Three hundred thousand tons steaming coal, for delivery at Hampton Roads—W. C. Atwater & Co., \$4.76; Castner, Curran & Bullitt, \$4.72; Consolidation Coal Co., \$4.75; Crozier Pocahontas Coal Co., \$4.76, delivered over twelve months' period; \$4.48 over six months' period; Smokeless Fuel Co., \$4.74; Sugar Creek Coal Sales Co., \$2.50; Fayette Smokeless Fuel Co., \$4.984; Haster & Co., \$4.83 over six-month period; \$5.01 over twelve-month period; Leckie Coal Co., Inc., \$4.65 over six-month period; \$4.73 over twelve-month period; C. H. Mead Coal Co., \$5.04; Pocahontas Fuel Co., Inc., \$4.58.

Thirty thousand tons run of mine for delivery at Boston—W. C. Atwater & Co., \$5.89, F. A. S. contractor's barges; Brinker Coal Co., \$5.94; Castner, Curran & Bullitt, \$5.89; Dexter & Carpenter, \$6.56 for delivery over six months, \$6.62 over twelve months; Eastern Fuel Co., \$7.02; Steamship Fuel Corporation, \$6.85; David E. Williams & Co., \$6.56 over six months, \$6.70 over twelve months. Fidelity Coal Mining Co., \$6.72; W. A. Marshall & Co., \$7.30; Metropolitan Coal Co., Boston, \$6.73; New England Coal & Coke Co., \$6.55 to \$6.70; Pittsburgh & Shawmut Coal Co., \$6.70; Pocahontas Fuel Co., Inc., \$6.13; Quemahoning Coal Co., \$7.55; Maritime Coaling Co., \$6.20; Seiler Coal Co., \$6.26.

Bids Plentiful at New York

Fifty-four thousand five hundred tons run of mine, for delivery at New York—W. H. Bradford Co., \$5.07 to \$5.27; Davis Coal & Coke Co., \$5.28 to \$5.45; Dexter & Carpenter, \$5.20 to \$5.44; Eastern Fuel Co., \$4.86 to \$5.81; Emmons Coal Mining Co., \$4.84 to \$5.09; S. Smith Coal Co., \$5.72 to \$5.99; Steamship Fuel Corporation, \$4.70 to \$5.05; Titan Fuel Corporation, \$4.79 to \$4.99; West Virginia Co., \$5.01 to \$5.39; Fidelity Coal Mining Co., \$5.01 to \$5.42; H. B. W. Haff, \$5.89; Hillman Coal & Coke Co., \$5.62 to \$5.83; W. C. Huber & Co., \$4.86 to \$5.17; Johnstown Coal & Coke Co., \$4.97; W. A. Marshall & Co., \$5.47 to \$5.67; Maryland Coal & Coke Co., \$5.09 to \$5.27 at Navy Yard; Quemahoning Coal Co., \$5.27 to \$5.40; Seiler Coal Co., \$4.89 to \$5.18.

Thirty thousand tons run of mine, for delivery at Philadelphia Navy Yard—W. H. Bradford Co., \$5.09 to \$5.37; Campbell Coal & Coke Co., \$4.80 to \$5;

Campbell, Peacock & Kimball, \$5.12 to \$5.27; Cosgrove & Co., \$5 to \$5.03; Davis Coal & Coke Co., \$5.03 to \$5.17; Dexter & Carpenter, \$4.98; Eastern Furnace Co., \$5.39 to \$5.59; Emmons Coal Mining Co., \$4.83 to \$4.98; Southport Coal Mining Co., \$5 to \$5.17; Steamship Fuel Corporation, \$5.01 to \$5.45; J. Tatnall, Lee & Co., \$4.94; Walcore Coal Co., \$4.87 to \$5.05; Weston, Dodson & Co., Inc., \$5.39; West Virginia Coal & Coke Co., \$4.53. David E. Williams & Co., \$4.96; Fidelity Coal Mining Co., \$4.97 to \$5.09; Hillman Coal & Coke Co., \$5.22 to \$5.37; W. M. Hollenbach, \$4.39 to \$4.53; W. C. Huber & Co., \$4.64 to \$4.84; Logan Coal Co., \$5.29 to \$5.48; W. A. Marshall & Co., \$5.25 to \$6.10; Maryland Coal & Coke Co., \$4.53 to \$4.65; Morrisdale Coal Co., \$4.54 to \$4.69; Quemahoning Coal Co., \$4.70 to \$4.88; Seiler Coal Co., \$4.69; Seaboard Fuel Corp., \$4.72 to \$4.87.

Thirty-five thousand one hundred tons run of mine, for delivery at Annapolis—Cumberland Coal Co., \$5.52 to \$5.72; Davis Coal & Coke Co., \$5.39 to \$5.558; Dexter & Carpenter, \$5.88 to \$6.11; Eastern Fuel Co., \$5.93; Steamship Fuel Corp., \$5.47 to \$6.94; West Virginia Coal & Coke Co., \$5.20 in cars; Fidelity Coal Mining Co., \$5.31 to \$5.61; Hall Bros. & Co., \$5.14 to \$5.44; Hillman Coal & Coke Co., \$6 to \$6.15; W. C. Huber & Co., \$5 to \$5.19; Johnstown Coal & Coke Co., \$5.46 to \$5.66; Quemahoning Coal Co., \$5.35 to \$5.49.

Fifty thousand tons run of mine for delivery at Washington, D. C.—W. C.

C. E. Bockus

Newly elected treasurer of the National Coal Association, in which office he succeeds S. Pemberton Hutchinson, the new president. Mr. Bockus also is president of the Clinchfield Coal Corporation, Dante, Va.

Atwater & Co., \$2.24; C. G. Blake, \$5.19; Brinker Coal Co., \$4.56; Chesapeake & Virginia Coal Co., \$2.21; Cumberland Coal Co., \$5.42; Davis Coal & Coke Co., \$5.28; Dexter & Carpenter, \$5.25; Eastern Coal & Export Corporation, \$5.36; Eastern Fuel Co., \$5.64; Emmons Coal Mining Co., \$4.96; L. A. Sneed Co., \$4.90; Steamship Fuel Corporation, \$5.47; White Oak Coal Co., \$5.30; David E. Williams & Co., \$5.18; Fayette Smokeless Fuel Co., \$4.99; W. C. Huber & Co., \$4.79; Johnstown Coal & Coke Co., \$5.08; Leckie Coal Co., Inc., \$4.97; Lick Run Coal & Coke Co., \$4.96; Logan Coal Co., \$5.51; W. A. Marshall & Co., \$5.27; A. T. Massey Coal Co., Inc., \$2.35 f.o.b. mines; New River Coal Co., \$2.52 f.o.b. mines; Quemahoning Coal Co., \$5.19; Seiler Coal Co., \$4.98.

Figures Close for Indian Head

Twenty-eight thousand tons run of mine for delivery at Norfolk, Va.—Md.—W. H. Bradford Co., \$5.52; Brinker Coal Co., \$5.49; Cosgrove & Co., \$5.63; Davis Coal Company, \$6.05; Dexter - Carpenter Company, \$5.82; Eastern Fuel Co., \$6.41; Emmons Coal Mining Co., \$5.61; South Port Coal Mining Co., \$5.82; Steamship Fuel Corporation, \$6.04; Weston, Dodson & Co., Inc., \$5.97; David E. Williams & Co., \$5.75; Seaboard Fuel Corporation, \$5.54; Fidelity Coal Mining Company, \$5.78; Hall Bros. & Co., \$5.71; Johnstown Coal & Coke Co., \$5.93; Logan Coal Co., \$6.08; W. A. Marshall & Co., \$6.06. Maryland Coal & Coke Co., \$5.98; Seiler Coal Co., \$5.77; Fayette Smokeless Fuel Co., \$5.16; Fort Dearborn Coal Co., \$5.35.

Twenty-five thousand tons run of mine, for delivery at Norfolk, Va.—W. C. Atwater & Co., \$2.24; Black Diamond Coal Mining Co., \$6.78; C. G. Blake, \$5.32; Chesapeake & Virginia Coal Co., \$2.22; Crozier Pocahontas Coal Co., \$5.18; Dexter & Carpenter, \$4.81; Eastern Coal & Export Corporation, \$5.18; L. A. Sneed Co., \$5.03; W. H. Brown Coal Co., \$5.37.

Hoover Urges Rail Mergers To Lower Coal Rates

Consolidation of railway properties as provided for in a bill introduced by Senator Cummins, Iowa, was indorsed by Secretary Hoover May 21 before the Senate Committee on Interstate Commerce.

Mr. Hoover said the plan would result in more equitable rates, as the rate structure could be reorganized without disturbing the present earning levels of the roads. It would permit relief in lower rates to agriculture and coal, he believed, by imposing a heavier burden on finished goods.

The most important preliminary to railway consolidation, Secretary Hoover declared, is the passage of such a law as that proposed by Senator Cummins, as the chief essential now is affirmative action by Congress. He suggested that neither the Interstate Commerce Commission nor Congress should do anything final in that direction, however, until the public had had opportunity thoroughly to consider and discuss whatever consolidation plan the commission may recommend.

West Virginia Institute To Discuss Stray Current, Shooting and Explosions

Methods of preventing the occurrence of stray current in coal mines will be described by E. E. Jones, superintendent, E. E. White Coal Co., Glen White, W. Va., at the meeting, June 17 and 18, of the West Virginia Coal Mining Institute, which will be held at Elkins, W. Va. Other notable addresses will be one by Charles M. Means, consulting engineer, Pittsburgh, Pa., on "Grounding of Electric Coal-Mining Machinery"; Engineering and Accident Prevention," by Newell G. Alford, mining engineer, Pittsburgh, Pa.; "Abuse of Explosives," by Arthur La Motte, E. I. DuPont de Nemours & Co., Wilmington, Del.; "Explosion Hazards in Coal Mines," by J. W. Paul, mining engineer, U. S. Bureau of Mines, Pittsburgh, Pa.; "Rock Dust as a Preventive of Coal-Dust Explosions," by Captain E. Steidle, supervisor, co-operative mining courses, Carnegie Institute of Technology, Pittsburgh, Pa., and "The Value of the Local Mining Institute" by Bruce S. Davis, chief engineer, Logan County Coal Corporation, Lunda, W. Va. J. J. Rutledge will lead the discussion of Mr. Means' paper. On the night of June 17 a banquet will be held, and during the course of the meetings, a visit will be made to the mine of the West Virginia Coal & Coke Co., where the "V" system of mining and conveyor haulage is in operation.

Urges Economy by Railroads In Use of Fuel Coal

Greater economy in the use of fuel coal by the railroads of the country was urged by R. H. Aishton, president of the American Railway Association, in an address before the International Rail Fuel Association, in Chicago, May 26.

"In 1923, when the railroads carried the largest freight traffic in their history," said Mr. Aishton, "it required 160.2 lb. of coal turned into steam to move one gross ton of freight a thousand miles or a thousand gross tons one mile. This was 2.8 lb. less in 1922 and 1.8 lb. less than in 1921.

"If the railroads used 1 lb. less of coal per ton hauled this year than was used in 1923 and moved the same ton mileage as in 1923, it would mean a total saving of \$3,165,000 in the fuel bill of the carriers in 1924 on the basis of the prevailing price of coal.

"In the last decade every known appliance for effecting economy has been installed on new locomotives, and to a very large extent on locomotives as they go through the shops, and while I won't undertake to say what the total expenditure has been, in the matter of superheaters alone it runs up over \$150,000,000 of capital expenditures, to say nothing of all the appliances that promote economy both in labor saving and in consumption of fuel.

"I think what we must immediately attack is the problem as it is, the tools as they are in our hands today, and by the application of knowledge, initiative and a desire to bring about accomplishment get an immediate result."

Will Idle Miners Get Aid?

In many union fields which have signed up their operators on the Jacksonville basis, appeals are being made to International headquarters for aid for the workless. The most recent appeal is from the miners of Kansas, who "won" from their employers on May 3. Having done the bidding of International President Lewis, they found that practically none of the mines was able to run, so their victory was hollow. On May 18 they petitioned Lewis for financial aid. Locals in the Pittsburgh (Kan.) district are voting on a proposal that every man who works five days a month be assessed \$1 a week to aid the others. About 2,000 in that region are working while 7,000 are jobless. The problem of aid for the workless is a live one in Illinois, where tremendous pressure is brought on state officials to break down the District 12 rule against issuing such aid.

Illinois Miners Vote Against Out-of-Work Benefits

Extending their biennial convention into its third week, Illinois miners deprived their president of the appointive power and decided by a vote of 369 to 130 that the finances of the district are in no condition to permit payment of out-of-work benefits. The resolution turning down the proposal for benefits reads as follows: "Owing to the large number of members now idle, we are unable to devise any means of raising finances that would make possible the payment of out-of-work benefits and therefore decide against paying same."

Approval of the three-year wage agreement reached at Jacksonville, Fla., was obtained over a strong minority opposition, which insisted that the shorter work day would solve the district's unemployment problem. President Frank Farrington denounced the 6-hour work day as impractical at this time. "The 6-hour work day," he said, "would stop every mine in the Central Competitive Field if it effectively replaced the 8-hour day at the same wages."

Earlier in the convention a resolution was adopted instructing the legislative department to co-operate with the American Federation of Labor in getting a federal law providing for unemployment compensation "out of industry."

Two proposals for old-age pensions also were offered. The first would tax every member \$2.25 a month and pay every miner who is 60 or over and who has worked 15 years continuously \$25 a month. The second plan would pay the same to miners 65 or over who have worked 20 years continuously, and would tax the members \$1 a month. It was reported that there are more than 4,301 miners over 60 in Illinois. Assessments would start July 1, 1924, and payment of the pension begun July 1, 1925.

Walsh Wants More Inspectors At Same Outlay

At a conference in Wilkes-Barre, Pa., last week twenty-one mine inspectors from various sections of the anthracite field discussed a proposition submitted by Joseph J. Walsh, Secretary of Mines, calling for reorganization of the State Inspection Bureau which would provide twenty additional inspectors without increased expense.

The reorganization plan calls for the division of the state into a smaller number of inspection districts, the reduction of salaries of some of the present inspectors, and appointment of twenty additional men. While the plan was received with favor by the mine inspectors, no action was taken. It will be presented to the bituminous inspectors before it is put into effect.

At present Mr. Walsh has fifty-five inspectors in the anthracite and bituminous fields, each presiding over an inspection district. With a smaller number of districts, each district would be in charge of a chief district inspector, and working under him would be a senior and a junior inspector.

The inspectors went on record as favoring legislation to compel the firing of blasts in the mines by electric batteries instead of fuses and squibs, as a safety measure.

The following anthracite inspectors attended the conference sessions: August McDade, of Taylor; Frank Kettle, of Nanticoke; S. J. Phillips, of Scranton; P. J. Moore, of Carbondale; M. J. Brennan, of Pottsville; C. J. Price, of Lykens; P. J. Friel, of Shamokin; J. J. Corgan, of Kingston; J. J. Stickler, of Hazelton; I. M. Davies, of Lansford; J. C. Reese, of Scranton; Evan Evans, of Coal Dale; L. M. Evans, of Scranton; B. I. Evans, of Mt. Carmel; D. J. Roderick, of Hazelton; William Reid, of Centralia; T. J. Williams, of Kingston; Archibald B. Lamb, of Shenandoah; P. J. Fenton, of Mahanoy City; D. T. Williams, of Scranton, and E. C. Curtis, of Kingston.

Ruhr Coal Miners Reject Proposed Mediation

The four German miners' unions have voted to reject arbitration proposals recently made in Berlin as a means for settling the dispute that resulted in a lockout at the coal mines in the Ruhr. The rejection was voted because the proposals failed to provide pay for overtime. The belief is that the operators will favor the arbitration proposals rendered through the mediation of Minister of Labor Brauns, and that the lockout will continue.

While the miners agreed to accept the covering schedule regulating wages they are holding out for recognition of their demands for overtime. They assert that they are willing to work in order to enable Germany to carry out the obligations imposed by the "Micum" accord and accuse the operators of arbitrarily keeping them from work.

The miners' unions warn members against yielding to Communistic propaganda, which is declared to be attempting to incite lawlessness throughout the Ruhr Basin.

J. G. Bradley Foresees Readjustment of Three-Year Wage Agreement

Alternative, He Thinks, Is Production Only During Maximum Demand by Mines Affected—Sees Investigation of Freight Differentials as Effort to Combat Non-Union Competition

Pleading the cause of the non-union operator and at the same time branding Governor Gifford Pinchot, of Pennsylvania, a political coward, J. C. Bradley, president of the Elk River Coal Co. and former president of the National Coal Association, aroused the members of the National Association of Manufacturers to a high pitch of enthusiasm May 21 at the annual convention of the association in New York City.

Touching upon the overdevelopment "which has been very much emphasized by union leaders and by the Coal Commission," Mr. Bradley said it is to the interest of the miners' leaders to get as many men on the union rolls as is possible and hold them there. Unionization of the coal industry or any other industry, if intelligently conducted, he said, would be to the great advantage of those industries, "but I have never seen it intelligently done."

Stating that the public has been led to believe that the coal industry is controlled by a few men who fixed the price and struck the profits in their pockets, Mr. Bradley declared there are more coal mines and coal-mining companies today on the verge of bankruptcy than have ever been known in any industry in this country.

Urges Competitive Wage Scale

Mr. Bradley contended that the best way to reach the right wage scale is by open competition within the labor market, saying that if "you pay too little, men won't come and work for you; if you pay too much, you can't stand competition. We are not only not guaranteed, but we are not even given that open competition in a large part of this industry today. We see two-thirds of the producing territory tied up to a rate of wages which has shut down those plants. Most of the coal which is coming to the market today is from the non-union fields.

"And this wage agreement which we have seen heralded by the political crowd as being a settlement for three years is by no means a settlement. What working man would agree to a settlement which would shut him out of work for three years? Either the coal fields of those northern states are going to produce coal only in the time of maximum demand, or else the miners in that section of the country are going to demand a readjustment of this agreement."

Telling the manufacturers that the only assurance they have of getting coal at a reasonable price above the cost of production is the non-union fields, Mr. Bradley continued:

"You can't get hard coal, you can't get your domestic fuel except at a price which is fixed by the United Mine Workers and the anthracite operators

and the Governor of Pennsylvania. And you have got to remember the political commission that you are paying to the Governor of Pennsylvania.

"When he made that award, it was so against the facts that the only deduction that could be drawn was that he was giving a subsidy to the organized hard-coal miner."

Stating that if the non-union operator is able to co-operate with his men on one side, whereas the union operator can't, the chances are that he will be able to co-operate with the consumer rather than the union operator.

Referring to the application before the Interstate Commerce Commission to change the freight differentials between the union district north of the Ohio River and the non-union districts to the south, Mr. Bradley said the reason for the application was that the union operator in his struggle with organized labor has failed.

Jacksonville Scale "Uneconomic"

"He has signed a wage scale which is uneconomic," he declared, "which is higher than he ought to have signed. He forgot that he was a quasi-trustee for his consumer; that he should have protected him and refused to sign that agreement. And now, having thoroughly messed the thing up, he is going to the Interstate Commerce Commission asking that freight rates be so readjusted that those who declined to sign—who didn't haul down their flag, who stood out for the open shop and free competition—shall have any advantage therefrom taken away from them."

"This particular case only asks for a readjustment in regard to rates on lake coal, but it is the entering wedge. When the principle in that case is established, when that differential has been widened so that the coal from the Central Competitive Field can get to the consumer at an advantage over their competitors in the non-union fields, then the same thing will be asked on every other rate north of the Ohio River."

Here's a Wet Mine!

The normal product of a coal mine in most states is coal, but you can't always tell about Oklahoma. That was the state in which an oil well produced ordinary, useless "wind gas" which turned out to be priceless helium. So there is less surprise in the news that a handful of investigators for the Volstead department of the state government got to prying around a coal mine near Scales, May 18, and found the mine was yielding quite a volume of beer. The officers arrested Sam Courtney, owner, and charged that he had beer down the shaft and was loading it out through the office. The officers' report showed not a single "no bill" on track.

Much Talk of Hazard Mergers

At least two consolidations of mine groups in the Hazard field of Kentucky are now discussed vaguely. One, aimed to effect the merger of about twenty-five mines, is making slow progress while the six or seven mine owners talk of valuations and stock distributions in the proposed consolidation and while the fate of the three Jewett, Bigelow & Brooks mines and the three Maynard mines, now in the hands of receivers, is decided. The six may be purchased by any one of several interests now bargaining for them, and may thus be brought into a merger if a merger is possible after a purchase is made.

The other consolidation is reported in indefinite language by P. B. Ver Planck, of Chicago. Mr. Ver Planck says that a large Chicago coal consumer has already reached an agreement with the owners of fifteen Hazard mines within a radius of 14 miles to buy the group and will complete the deal within the next forty-five days. Thus he says this interest will acquire the heart of the No. 4 Hazard seam and will re-equip most of the mines, install mechanical loaders where it is practicable, and otherwise rehabilitate the properties. A selling agency to handle part of the output on a commercial basis is already in existence.

Practical Pointers For Electrical And Mechanical Men

Waste Saturating Tank For Mine Service

The most common method of lubricating the bearings of locomotives and mine-car journals is by means of oil and waste. To get the best results, the waste should be well saturated before it is packed in the oil wells. This is done by soaking the waste for a certain definite time in oil and then setting it aside to drain.

The materials used for this work should be a clean, long-fibre wool waste and a good reliable grade of neutral mineral car oil. Such waste will absorb about four times its weight of mineral oil.

SOAK WASTE FOR 24 HOURS

The waste is placed in a closed can or tank of oil and left to soak for at least twenty-four hours. During this process, some companies apply heat, thus reducing the time required to saturate the waste. The waste is then lifted out of the oil and placed on a screen or grid and drained until all excess oil has dripped off. This draining takes about twenty-four hours, after which the saturated waste is placed in closed cans ready to be packed in the oil wells.

A very convenient and efficient tank, designed for doing this work, is shown in the figure. The dry waste is placed in sections 1, 2 and 3, and the fresh oil in section 5. By means of the pump on top of the tank, the oil from section 5 is lifted into chambers 1, 2 and 3, which are filled with waste. After the waste has thoroughly soaked for

twenty-four hours, the oil is drained back into tank 5, and used again. About twenty-four hours after the oil is drained off, the waste is ready for use. Chambers 4 and 6 are used to re-saturate old waste. The oil used for this purpose is kept separate from the new oil. Large clean-out plugs are provided for both oil chambers, which are also fitted with float gages to indicate the amount of oil in them.

A very simple and cheap tank can be made with one or more chambers, having a screen or grid shelf about half way down on which waste is placed to drain after being saturated. The dry waste is placed in a wire basket and immersed in the oil contained in the lower half of the tank. When thoroughly soaked, the basket is lifted onto the shelf and the oil drains off.

One large company has in operation a very successful tank which supplies waste for 1,600 cars. Their system consists of two tanks, approximately three feet wide, four feet long and two feet deep, with drain boards on both ends. New waste in one tank is used for armature bearings and old waste in the other is for use in axle bearings and journal boxes. The tanks are of double wall construction, a hot water jacket being used to keep the oil at an even temperature of approximately 120 deg. F. Each tank holds about 75 gallons of oil and 110 pounds of waste. The waste is left in the tanks three hours, after which it is removed and left upon the drain board several hours until ready to be placed in containers for transportation to one of the repair shops or lubricating centers.

Tank Where Wool Waste Can Be Thoroughly Saturated

Oil is pumped from compartment 5 into compartments 1, 2 and 3, and there it is poured over the waste. The excess oil is drained off through the screen at the bottom of the upper compartments. Sections 4 and 6 are used for re-saturating old waste. Steam coils may be used to make the oil flow more freely and thus increase the saturating capacity or effectiveness of the tank.

Instrument Records Abnormal Voltage Surges

Because of the high frequency of abnormal voltage surges, it has always been very difficult to obtain detailed information concerning them. Ordinarily, the cause of such surges is unknown and, as a result, information regarding such sudden impulses is rather limited, leading to questionable conclusions about their cause, effect and remedy.

To record such abnormal voltage surges on transmission lines the Klydonograph has recently been developed by J. F. Peters, of the Westinghouse Electric & Mfg. Co. This instrument makes a graphic record of voltage surges of extremely short duration, indicating at the same time the polarity, magnitude, and steepness of the waves.

Fig. 1—Diagram of Klydonograph

This instrument consists of a photographic plate which, when developed, shows the shape of the high voltage surge impressed on the instrument.

The principle of operation depends upon a discovery made in 1777 by Dr. Lichtenberg, who found that if he discharged a condenser, such as a Leyden jar, across a spark gap onto a terminal in contact with an insulating plate placed between the terminal and a ground plate, and then removed the terminal and sprinkled powder over the plate, the small grains of powder would arrange themselves in a peculiar appearing figure. Later, it was found that by using a sensitized photographic plate, the emulsion in contact with the terminal showed the same peculiar figure when developed.

The new instrument in its simplest form is indicated in Fig. 1. If a voltage is impressed between the terminal and the ground plate, as at *E*, figures will appear on the photographic plate that give pertinent information concerning the nature of the voltage impressed. If, for instance, the voltage is in the form of a surge that is unidirectional, with a sheer front or a tapered front, the figure on the photographic plate will differentiate between the tapered front and the abrupt front, and it will also indicate whether the surge was of positive or negative polarity. The size of the figure also gives the magnitude of the surges, although the positive and negative figures have quite

Fig. 2—Instrument Operated by Clock

When equipped with a clock, this device shows the exact time of any line disturbance.

different proportions. Usually the figures for the positive surge are considerably larger than those for the negative surge of the same magnitude.

For practical use, the instrument is made continuously operative and is capable of recording the exact time of the occurrence of any disturbance. Fig. 2 shows an instrument suitable for such applications. This device makes use of a 10 x 12 in. plate in a special plate holder. The moving parts are driven by a clock that makes one complete revolution in 24 hr. The device is practically a zero-current instrument and therefore can be connected to the line electrostatically. This makes it possible to use the instrument on high voltage lines without introducing the hazard of an insulation breakdown.

Fig. 3 shows the connection used to measure the steepness of the voltage wave. A counterpoise is run underneath or alongside the transmission line for 1,000 or 2,000 ft. with the far end connected direct to ground and the near end grounded through a high impedance. The Klydonograph is then connected between this balancing wire and the ground.

MEASURES STEEPNESS OF WAVE

The voltage induced in the counterpoise is a measure of the steepness of the current wave, and since the current wave and the voltage wave have exactly the same shape, it gives a measure of the steepness of the surge front. By comparing simultaneous readings of the instruments, one connected to the line through the electrostatic potentiometer and the other to the counterpoise, the following information concerning the surge may be obtained: Magnitude, polarity, steepness of front, and the direction in which the surge is traveling on the transmission line.

Magnitude and polarity are obtained directly from the first mentioned instru-

Fig. 3—How Instrument Is Connected to Measure Steepness of Surge

The counterpoise, run parallel to the transmission line, operates the instrument. In this way, it is possible to get the characteristics of the surge wave without connecting any recording devices directly to the line wires.

ment, steepness of front directly from the second, and from the relative polarity of the two figures, the direction in which the surge is traveling may be obtained. If the polarity of the two figures is the same, the surge is of the same polarity and is traveling in the direction fixed by the manner in which the recorders are connected to the system.

If the figures are of different polarity, the surge is of the polarity indicated by the recorder connected to the potentiometer and is traveling in the opposite direction from the one previously mentioned.

Quick Repair to Important Fan Motor Starter

Many accidents and delays due to the breakdown of electrical equipment are really far less serious than those which happen to mechanical apparatus. The reason why a small electrical failure creates an impression in the mind of the operator that something very serious has happened is mainly due to a lack of knowledge of electricity. If the men at the mines would try to understand their work a little bit better, I am sure that many a so-called serious delay will seem like nothing out of the ordinary.

Fig. 1—Transformer Connections to Motor

When the starting panel was destroyed it was impossible to make a quick repair to the transformers and get the fan motor going again.

However, it is interesting to see how quickly some electricians work and here is an example showing how simple and easy it was for one to solve what appeared to be a very perplexing problem to the mine foreman.

The starting panel connected to the alternating-current fan motor driving the only fan at one of our mines was damaged. The starting transformers were completely destroyed and the motor had stopped.

It was still early in the day when the mine foreman learned that the fan had stopped. The miners had been at their places for a few hours and all the company day men had gone inside the mine and were at work. To shut down the mines for the remainder of the day would have meant a loss of tonnage and nearly a total loss of the overhead charges for the day, because the men had started work and would have had to be paid for nearly a full day.

Fig. 2—Starting Resistance in Circuit

Several banks of locomotive resistance were placed in the circuit. In this way the starting voltage for the motor was sufficiently reduced to prevent a high inrush current and the motor was started just as smoothly as with the usual starting transformers.

Soon after the electrician arrived he saw that it was impossible to repair the starting transformers which were connected as shown in Fig. 1. All three transformers had been badly burned by the heavy current.

The power supply to the fan motor was 440 volts. The electrician quickly reasoned that he could soon have the motor running if some means could be provided to reduce the line voltage sufficiently to provide a reasonably low starting current. I suppose he said to himself, "the transformers reduced the line voltage, therefore resistance in the circuit will do the same thing."

RESISTANCE USED FOR TRANSFORMERS

No 440-volt resistance was available but the electrician knew that 250-volt locomotive resistance was rated high enough to stand 440-volts, so he quickly gathered several banks of locomotive resistance together and connected them into the starting circuit of the fan motor as shown in Fig. 2.

By closing a double-pole starting and running switch, first in the starting position and then in the running position, the fan motor was started and the fan kept running the remainder of the day.

There was nothing unusual about this scheme but it only goes to show how many an idle day may be avoided by a little intelligent consideration of a simple electric problem.

ELECTRICAL ENGINEER.

Pack Locomotive Armature Bearings Regularly

Even the ordinary type of motor bearing requires efficient lubrication. The waste, preferably wool, is first soaked in a good grade of car oil for about 24 hr., and then allowed to drain, after which it is packed firmly in the axle cap up to and around the bearing window. The axle cap is then filled up to within an inch of the top with waste packed comparatively loose. It is considered good practice to repack these bearings every three months, putting new waste close to the axle. All old waste should be removed about once every year and the bearings repacked with new waste.

Discussion

"Doctoring a Sick Industry"

Some Retailers Probably Adulterate Good Coal but the Practice Is Not Only Improper but Fatal to Successful Business—Sickness of Industry Due to Poor Quality and Bad Merchandising

BY H. B. BLAUVETT
Hackensack Coal & Lumber Co.,
Hackensack, N. J.

UPON reading *Coal Age's* editorial criticism in March 13, page 377, of my anthracite article which recently appeared in the *Printer's Ink*, I thought that "the pot was simply going to call the kettle black" and, having so passed the buck from producer to retailer, let it go at that. Not so. There is real meat in that criticism and I feel that it is intended in the right spirit.

First, there is no battle on between wholesalers and retailers. Our interests are, or should be one: we both want to sell as much coal as possible at a fair profit—with repeat sales! Bad coal qualities make the latter impossible, so we are both interested in the very best quality of coal obtainable.

SNOW BIRD RETAILERS TROUBLE TRADE

Coal Age raises a good point. There are undoubtedly "snowbird retailers" as there are "snowbird producers," and probably they have indulged in the dishonest practice of mixing the "abominable, unburnable stuff" with good coal. Again reputable producers have common cause with reputable retailers, for are not both interested in cleaning up the industry and putting it on a basis of honest competition where they will not be at a disadvantage.

Let no mind draw a distinct line of cleavage between producer and retailer. Their interests are identical. Each is a direct necessity of the other. Any good producer knows that a live, reputable outlet for his coal is more to be desired than much, very much, pure gold, in fact he is not to be bought.

The solution of the "snowbird retailer" is so simple that his occurrence is not a cause of serious worry. Let the reputable producer make it possible for the reputable retailers to obtain good coal and the "snowbird" will not be able to continue adulterating his good coal if he wishes to stay in business. The public is quicker to discover bad qualities in coal than anything else. The honest retailers try to stand behind their coal and most of them take out unsatisfactory coal immediately upon complaint thereon replacing it with new well-screened coal at no charge. This costs money. The "snowbird" could not afford to keep doing it

and if he didn't do it his customers would drop him and go elsewhere.

Such news spreads quickly, and retail trade invariably flocks to the retailer who has the best coal. Make it possible then for the reputable retailer to get good coal, and you will put the "snowbird retailer" out of business. We are heartily in favor of any move to promote quality in coal, in fact, disinterested public inspectors at the retailer's yard sound good to us. A careful reading of the report of the "Coal Commission" will show the quality phase to have been more abused by the "snowbird" producers than the retailers. It is common knowledge in the trade that some producers do adulterate good coal with the unburnable stuff. Unquestionably many reliable retailers took "the unburnable stuff" last year because they had to get something. The pressure of the public was heavy, and the need was pathetic.

PRODUCER CANNOT RETAIL HIS COAL

The thought of the producer retailing his own coal is possible but not probable. Let him try the heart-breaking detail of the retail business. A ton here, a ton there, the large coal contracts cut down to the bone, and bad credits with slow collections on top of that. It's a slow and, unless times are particularly favorable, not an especially profitable game. Compared with the results derivable from corresponding effort centered on his producing problems, the operator could not afford to spend his time fooling with retailing.

Coal Age aptly hits the nail on the head when it says that popular outcry and legislation would never permit this consolidation. Nor is such a step advisable. The retail end is a distinct business in itself and must be run as such—the continual effort must be to "keep the people pleased," a difficult and sometimes thankless task.

A word more. The last paragraph of the *Coal Age* editorial is the kernel of the whole nut. We agree: Advertising will pay (if not, why then the full-page ads in *Coal Age*?) but advertising is useless unless truthfully used and those used truths are backed up with quality in the advertising article. The causes of "sickness" in the hard coal industry are still two (excluding labor), (1) a poor quality. (2) bad merchandising—including lack of public education through advertising. With proper advertisements, egg and pea can be merchandised and this without breaking down the former to stove

and nut as *Coal Age* tells us on page 407 is being done with egg coal to make its merchandising possible. With advertising, buckwheat can be sold to the general public by teaching the consumer how to burn it. As to the costs of advertising, if the buckwheat market could be slightly stiffened it would be easy to pay the charges.

ADVERTISING A TWO-EDGED SWORD

Advertising is a two-edged sword; if strikes make it impossible to ship good coal tell the public so that they will be prepared and know the producers are not at fault. The coal industry has nothing to conceal. Tell all the facts and the public mind will be fair.

If the "companies" can't get together, let them advertise individually. The Philadelphia & Reading and the Lehigh Coal & Navigation Companies have already begun. Let the others follow their good lead. The solution of the hard-coal industry is to produce good coal and sell it all—steam sizes included—with steady educational advertising.

I must say a word in personal defense. You overlook the fact that "What's wrong? Too many mines. Too many miners. Too much seasonal variation in consumption. Too much railway politics," was plainly labelled a quotation from *Collier's Weekly*. Though there seems good sound truth in it I disclaim being the originator of the ideas contained therein.

Second, I am no expert, and make no claims as such. An expert is an unhealthy proposition; he usually says (as did *Coal Age*) "Believe this expert; he knows." The minute a man claims "he knows" it means that he thinks he is too wise to learn. Let us hope that the hard-coal industry is not too wise or self satisfied to learn. The fact still remains that it is an industry characterized by bad merchandising. Let's do our best to clean it up by turning out a good quality of coal and advertising that fact. My plea is for the honest producers and the honest retailers to get together in a common cause and put the coal business back on a sound honorable basis, for no business can survive unless founded upon honesty.

Lehigh University, Not Illinois

At the bottom of page 606 of the April 24 number of *Coal Age*, the information regarding Prof. A. C. Callen is somewhat misleading. Professor Callen's "Alma Mater" is Lehigh University, as he graduated from the course in Mining Engineering in June, 1909, receiving the degree of E.M., and the degree of M.S. in 1911.

Professor Callen went to the University of Illinois some years later and was associated with the late Prof. H. H. Stock, (also a Lehigh E.M. but of the class of 1888), up until the time of going to the University of West Virginia in 1917.

Here at Lehigh, we feel very proud of Professor Callen, and congratulate the University of Illinois upon the selection which has been made for the Deanship of the School of Mines.

HOWARD ECKFELDT.
Prof. of Mining Engineering.
Bethlehem, Pa.

Note—E. Blauvett, president Hackensack Coal & Lumber Co., writes that H. B. Blauvett was leaving for England when he received the editorial "Doctoring a Sick Industry." He took it with him and answered it while abroad. This accounts for the delay in making reply.

Production And the Market

Inertia Still Pervades Bituminous-Coal Markets; Anthracite Trade Notably Active

The revival in industry promised as the result of surveys in the industrial centers of the country is not yet in sight—at least visible evidence of it is still lacking. If the prophesied upturn bears any relation in size and strength to the so-called breathing spell preceding its inception it ought to be a sizable movement, for except during a labor disturbance the present period of depression surpasses anything of the kind in recent years in the coal trade. Save for a few temporary spurts due to cool weather the prolonged condition of dormance in the markets continues unabated. Running time at the mines shows no appreciable improvement anywhere, production in the southern Ohio field—an extreme example—holding around 10 per cent of capacity. Shipments to tidewater continue to shrink and the demand for lake tonnage is lagging considerably behind that of last year at this time. One of the few bright spots in the trade during April, the export movement at Baltimore, has practically faded out of the picture. May began auspiciously, but after the 2d there was a lapse of seven days before the next cargo cleared, and since the 12th the bottom of the export trade apparently has dropped out completely.

Navy Bids Bring Out Keen Rivalry

The Navy Department's call for bids on supplying 330,000 gross tons of steaming coal for ships and 438,600 tons of coal for navy yards and other shore stations brought out the keenest kind of competition. Nearly one hundred companies submitted tenders, most of them making offers on a number of schedules. The award of contracts, which is expected to take place this week, may provide the needed impetus to start the market in motion.

Coal Age Index of spot prices of bituminous coal declined 3 points during the week ended May 26, registering 167, the corresponding price being \$2.02.

Dumpings at Hampton Roads for all accounts during the week ended May 22 totaled 241,490 net tons, as compared with 261,732 tons dumped during the preceding week. Coal dumped at Lake Erie ports during the week ended May 24, according to the Ore & Coal Exchange, were as follows: Cargo, 529,883 net tons; fuel, 35,478 tons. The totals for the previous week were 523,499 tons of cargo coal and 35,697 tons of fuel coal.

Production of bituminous coal declined slightly during the week ended May 17, according to the Geological

Survey, the output being 7,074,000 net tons, compared with 7,121,000 net tons produced during the previous week. The output of anthracite was 1,895,000 net tons, a falling off of 29,000 tons from the figures for the week ended May 10.

Intermittent labor troubles at large company operations have made it difficult for dealers to obtain as much company anthracite as they desire, with the result that the demand for independent coal is strong and prices are holding firm. The call for stove is still notably strong, playing its part in the activity for egg and chestnut. Production is picking up, and the market is expected to ease up somewhat.

Midwest Buys Some Lump

Unseasonably cold and raw weather throughout the Middle West caused a slight pick-up in the domestic business of that section last week. Many a coal bin that had been swept clean suddenly required another ton, with the result that the leading domestic coals got a dribble of much-appreciated business. A little hard coal moved readily along with the small stocking trade the retailers have been having and the call for smokeless picked up noticeably in view of the shortage of supply that happened to be on hand. Good Pocahontas even rose 15 to 25c. for a day or two as a result of the situation. Midwestern lump and egg also felt the cold a bit.

Generally speaking, however, the dullness of the whole Midwest industry continued. Contracting that was expected soon after May 1 has not yet materialized. Railroads have been signing up some small business at low prices, but industry has been notably backward. Prophecies of late summer industrial improvement have not moved purchasing agents to action yet.

The running time of Midwest mines was improved by a slim margin during the past week, partly because everybody was keen to get all the benefit they could out of the

cool weather and partly because a handful of mines have been opened "for better or for worse" in a determined effort to get business at any price rather than to stay down. Most of these operations have been able to get screenings business, but little else. Crushers have been working more than usual. Good Franklin County screenings move at \$1.90 and weaker grades from the same county bring \$1.75. Central Illinois sells for \$1.50@1.75 and Standard district fines move at less than that.

The St. Louis market is as low as it have ever been. There is no demand worthy of note for anything. In fact anthracite business is duller than most observers thought it could ever get. About the only thing that sells to householders is local coke. Big buyers of steam coal, both city and country, are taking some screenings, but the volume is not great. Wagonload steam business is dead along with domestic. The trade is now looking forward to some sort of improvement immediately after June 1.

Kentucky Drones Along

Things are quite dull in Kentucky. There is a little business from various scattered industries and prospects of some business from retailers, who are taking some stocking orders for future delivery. There has been just a little

* Net tons, f.o.b. mines. † Advances over previous week shown in heavy type, declines in italics.

Index	1924		1923	
	May 26	May 19	May 12	May 28
Weighted average price	167	169	169	217
	\$2.02	\$2.05	\$2.05	\$2.63

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913-1918," published by the Geological Survey and the War Industries Board.

coal moving to domestic consumers and steam plants as a result of several cold days this month. Steam heat in office buildings on May 20 in Louisville is most unusual. However, immediate coal appears to be coming from yard cleaning rather than orders placed with mines.

Railroad consumption is reported fair and there is the usual run of small orders, representing coal moving to industries, utilities, etc., but Lake and Northern buying hasn't opened much as yet. Lower quotations are to be had on western Kentucky, but eastern Kentucky is firm, although some Hazard screenings are quoted as low as 95c., after a period of \$1 or better. Practically no screenings are offered out of the western Kentucky market, but price hasn't advanced, due to the fact that it is now at the mine-run level. Western Kentucky prices range from \$1.65 for mine run to \$2.35 for 6 x 14-in. egg.

Southern West Virginia mines in both high and low volatile territory are increasing production to some extent. Supply appears to be somewhat in excess of demand, though little distress coal is reported. There is a comparatively light demand at tidewater and yet prices there remain about the same on smokeless owing to the fact that smokeless mines are sending more coal to the lakes. High volatile splint lump is still hard to move.

Price Cutting in Northwest Eliminated

A drop in the price of screenings in Youghiogheny and Hocking, which are off to \$3.75 each, and a general tendency to eliminate the cutting reported a week ago featured the market at the Head-of-the-Lakes last week. There is little or nothing doing in either hard or soft coals, however. The price cut in screenings is an equalizing movement and

should not be construed as a possibility of further reductions. Many of the companies are bidding on large lots of coal for the independent mining companies, and in these cases the prices are off list. In one case it is known that 5,000 tons of Youghiogheny lump went for \$5.50, which is 50c. below list.

Receipts at Duluth were lighter last week. Only 18 cargoes entered the harbor. One was of hard coal. Docks are trying to clean old stocks before going into new coal and it is expected that shipments will gradually fall off until about midsummer. The Steel Corporation is bringing up very little because of its stock augmented by the large purchase from the defunct Superior Coal & Dock Co. Total Duluth-Superior receipts thus far this season are 451,660, tons of soft coal and 108,930 of anthracite.

In spite of the cold snap, trade is dull throughout the Northwest, even in small-lot business. Steam-coal buying in Minneapolis is markedly slow with big buyers sitting back with no money to spend. Prices are wabbly, especially on rail coal from Illinois. Lump from there is offered all the way from \$2.50 to \$3 with little trade going on. Contracting is slow indeed.

Milwaukee trade is as slow as that of the rest of the country. The few buyers that are in the market are taking coal piecemeal. Manufacturers are buying slowly because their business is dragging. Country trade, both domestic and steam, is extremely sluggish. Anthracite receipts at Milwaukee for the season to date are 108,362 tons, which is up to standard, but soft-coal receipts total only 226,199 tons, which is 40 per cent less than last year.

West Is Still Sluggish

There is little activity in the Southwestern district. Few mines are working. The majority of these are shovel mines, capable of supplying the present industrial demand with slack and crushed mine run at \$2.50@2.75 a ton. No operators have announced storage prices on Kansas coal, and some say there probably will be no reduction of the present quotations of \$4.50 for lump, \$4 for nut, \$3.50 for mine run and \$2.50 for screenings.

A reduction of 50c. a ton on Arkansas semi-anthracite lump from winter quotations will become effective in June, when reduced freight rates to Missouri River points take effect. There is practically no work in Arkansas now.

The Colorado market continues slow with very little if any demand for other than domestic sizes. Mines worked an average of 19 hours last week and the weekly reports from the operators show that 35 per cent of the working time lost was attributed to "no market." There has been some talk as to a slight advancement in prices, but as yet there has been no change.

Utah operators are low in spirit because practically the entire demand for fuel has dissolved except for a dribble of domestic coal and a little steam coal for the smelters and cement plants. Prices are unsettled. Retailers are trying to get a reduction at the mines so as to make a lower stocking price to their trade. Lump is now \$3.50 and operators feel that that ought to be rock bottom. Mine tracks are burdened with "no bills."

Tone Improves at Cincinnati

A much better tone pervades the Cincinnati market than for some time, the feeling being that the worst is past. Lake business is again hitting its accustomed groove about this time of year, when the free movement from the lake ports sets in. Logan County operators are getting the best of the business, more through the fact that they have been able, through low cost of production, to undersell southeastern Kentucky producers.

The coal trade at Columbus shows little change from last week. Steam business is rather quiet, although there are signs of some improvement in the demand, as some larger consumers are nearing the point where they will be forced to replenish supplies. Utilities are buying to a certain extent and some business from iron and steel concerns also is being booked. Contracting is still quiet, as a large number of users are content to buy from the open market rather than to enter an agreement. Most of the contracting reported is simply the renewing of formal contracts. With output reduced there is not so much distress coal on the market and consequently prices are more steady. Domestic trade is still dull. Some Pocahontas and smokeless varieties are moving and there also is a limited demand

for splints. Lake trade shows little strength as far as Ohio coals are concerned. A considerable tonnage is being loaded at the lower lake ports but this is produced largely in West Virginia and Kentucky.

Market conditions at Cleveland are exceedingly poor, inquiries being scarce. Industry is lagging, fuel consumption is correspondingly curtailed, and these conditions, coupled with the inroads being made by non-union fields have produced a depression not experienced in this field in a decade. Little contracting is being done, steam buyers looking to the open market for fuel supplies so far as the immediate future is concerned.

There is no noticeable improvement in the Pittsburgh coal market. Late production reports for the rail mines of the district show 20 to 21 per cent operation, against 18 to 19 per cent early in April. The increase probably is due to some shipments of lake coal by lake shippers who control mines in the district. Line consumption of coal has decreased considerably. Steel-mill operations continue to decline. There is talk among operators of union miners making overtures for reduced wages so as to develop some business, but little credence is placed in such gossip.

Demand at Buffalo is pretty light. There seems to be too much coal, in spite of the sharp cut in production, and too many people selling it.

General Inertia in New England

The market for steam coal in New England drags along with no sign of improvement. Shutdowns are the rule in the textile and shoe industries, and other lines share what appears to be a general depression. In no direction is there buying of any moment, and even public institutions in some instances are purchasing only sparing amounts, hoping that during June and July they may be able to obtain lower quotations than now prevail.

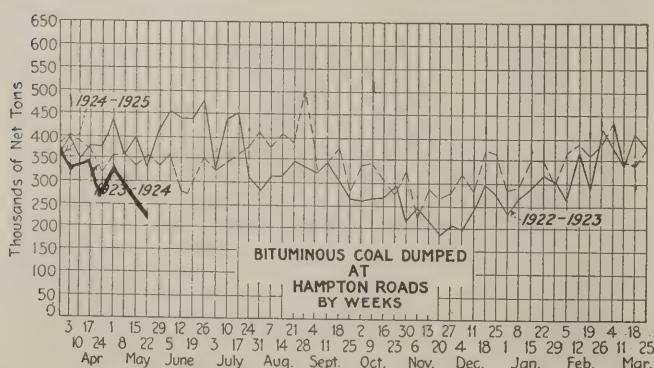

The price level f.o.b. vessel at Hampton Roads varies from \$4.35 to \$4.50 for No. 1 Navy Standard, but next grades have been reported sold at \$4@4.10. Accumulations are not large, but they are sufficient to keep prices below the \$2 per gross ton contract basis. Fair tonnages are moving off shore and along the coast on seasonal arrangements, but for spot business there is next to nothing doing. Factors at this end who rehandle at their own wharves are exerting steady pressure on buyers in order to make room for weekly arrivals, but no one is enthusiastic over results.

For inland delivery prices on cars at Boston, Providence and Portland follow very closely the fluctuating market at Norfolk and Newport News, marine freights, discharging and insurance aggregating about \$1.15. In other words the on-car figure is now about \$5.50 for lots in excess of a few hundred tons, while for anything approaching a comprehensive order the trade has shown a willingness to accept offers down to \$5.35.

All-rail from central Pennsylvania the movement east of the Connecticut River continues extremely light. The same applies to shipments via the Philadelphia and New York piers. Even gas coals are being dumped in relatively small tonnages, and there is a great dearth of orders for coal of any grade at any of the piers.

Atlantic Seaboard Consumers Indifferent

Nothing has developed to change the status of the market at New York. Buyers continue indifferent to inducements offered to encourage restocking while transportation is good. Prospects, however, are bright and there is confidence in the immediate future of business. Most of the

coal available to the spot buyer is non-union product. Quotations for coal at tidewater remain steady despite lower receipts and the clearing away of distress tonnage. Cars on hand dwindled to less than 1,000 cars one day during the past week, but a few days later had nearly reached the 1,500 mark. The average was around 1,200 cars.

The market at Philadelphia continues inactive, consumers buying the minimum. It looks as if buying is to be left until coal is absolutely needed. Prices may be said to be holding firm, but only because the bottom has long since been touched. Business at tide is negligible.

The trade at Baltimore continues to plug along at a slow and unsatisfactory pace. Price variations are not extensive at present, for there is not enough active demand to bring up quotations sharply even for specialized coals and quick delivery. Consumers are buying in small lots for immediate needs only and there is practically no storing of moment. The export movement apparently has collapsed.

Business is coming in very slowly at Birmingham and is of comparatively small volume in aggregate. Consumers not having contracts are buying fuel needs in very competitive spot market.

Anthracite Market Retains Much Strength

Demand for the domestic sizes of anthracite at New York remains sufficient to absorb all sizes; the call for stove coal has been mainly instrumental in keeping egg and chestnut active. Chestnut continues to be more plentiful than either egg or stove and could be gotten from some shippers below the average quotation of \$9. Egg is nearly as strong as stove, but the demand is a trifle easier and would drop off considerably if the demand for stove became easier. The market for independent coals remains strong largely because of the inability of retail dealers to obtain sufficient company coal to supply the wants of their customers. This is due in large part to labor troubles. However, production is slowly recovering and with more company coal arriving in the New York market an easier situation is looked for. There has been a let-up in the demand for the buckwheat coals. No. 1 buckwheat is considerably easier and only the better grades are bringing top prices. Rice and barley are firmer, while birdseye is moving steadily. Unreasonable weather at Philadelphia has kept the market fairly active. Orders, however, are dropping off. The industrial situation is so unsatisfactory that workers are getting less money on account of curtailed working time.

Coke Output Slightly Higher

Coke prices are lower as a result of several important operators reducing wages to the 1917 scale, a cut of about 33½ per cent. The remaining independents will reduce soon. They have had hopes that the Frick company also would reduce, but this seems improbable. After seven weeks of steady decline, the output of beehive coke recovered slightly during the week ended May 17, when, according to the Geological Survey, 182,000 net tons was produced, as compared with 178,000 tons during the preceding week.

Foreign Market And Export News

British Markets Quiet and Irregular; Inquiry Indicates Better Outlook

The Welsh coal market is quiet and irregular, though the drop in prices has resulted in stronger inquiry for shipment during the next month or six weeks. This slight fillip is, however, somewhat discounted by the delay in shipping as a result of recent stormy weather. The foreign demand is very slow in recovery and the industry as a whole is still in a state of depression occasioned by the slump and the fear of a stoppage.

The downward trend of prices has been to a large extent arrested by the improved inquiry, though some operators are still offering concessions to effect immediate clearances. There has been some slight inquiry from South America, but buyers maintain a hand-to-mouth business. The Egyptian Government and the Sudan railways have ordered Monmouthshire large 100,000 metric tons at 38s. 4½d. and 50,000 tons at 38s. 2d. c.i.f. Alexandria.

The Newcastle market probably is as depressed as it has ever been, though, as in Wales, the demand has improved slightly on account of the lower prices. The Amsterdam gas works is inquiring for 10,000 tons of gas coals, and the Danish State Railway is in the market for 30,000 tons of steams for July to December shipment.

Production by British collieries during the week ended May 10, a cable to *Coal Age* states, was 5,220,000 tons, according to the official reports. This compares with 5,685,000 tons during the week ended May 3.

Business and Prices Slump at Hampton Roads

Business at Hampton Roads continues on the decline, with demand slumping and production at mines serving this port falling to a low level. Prices have slipped in keeping with the general trend of business. Lake shipments have begun to pick up, but the

majority of shippers have contracted direct from the mines or are moving coal from their own mines for the lake trade. Coastwise business is improving somewhat, but foreign movement and bunkers show little life.

The tone of the market is extremely dull. Shippers are disappointed over the situation, having expected better business. Buyers, apparently, are not willing to come into the market for more than their immediate needs.

French Markets Quieter in Tone In Sympathy with Iron Trade

The French coal market is beginning to feel the influence of the quietness of the iron and steel industry. Not that the French mines are complaining of lack of business, but the demand is less urgent. The demand for house coals has improved somewhat since the beginning of the month.

The summer prices for British anthracites and Ruhr briquets have been established for May only, but for other grades the June rates will be 4 fr. higher than those of May; July, 5 fr. above those of June, and August, 6 fr. above those of July.

Imports from Cardiff have declined noticeably during the past week, in spite of a decrease in the prices at the shipping docks.

Rolling stock has been supplied regularly to the mines, and freight is lower at 22.50 and 22 fr.

Deliveries of indemnity fuels are now averaging 42,700 tons daily. By an agreement just signed by France, Belgium and transport firms for regulating shipments of indemnity fuels by the Rhine, 500,000 tons monthly will be shipped through Strasburg and 350,000 tons through Rotterdam and Belgium.

French coal and lignite production in March totaled 3,772,734 metric tons, against 3,648,878 tons in February. In these two months there were 26 and 25 working days respectively, the daily

average output being 145,100 and 145,955 tons.

During April the O.R.C.A. was supplied with 592,332 tons of coke, or nearly 20,000 tons daily. From April 28 until the lockout the deliveries fell off to about 12,400 tons a day.

News Items From Field and Trade

ALABAMA

The Rainbow Coal Mining Co., Montgomery, has filed articles of incorporation with the Secretary of State. The company will engage in general mining business, having an authorized capital stock of \$100,000, with \$80,000 paid in. Incorporators are Homer F. Baird, Q. M. Selzer and Leonard B. Baird.

The Cahaba Domestic Coal Co., Inc., has filed papers in Birmingham, with capital stock given at \$3,000. The company was incorporated by Eudora, E. J. and E. R. Blackwood, Birmingham, and will engage in coal mining, etc.

Several independent coal companies, including the De Bardeleben and Pratt Consolidated, have reduced wages of miners.

COLORADO

During April Colorado mines produced 722,424 tons of coal, this being a decrease of 24,693 tons from April, 1923. The total number of men employed in and about the mines in April of this year was 12,943.

KENTUCKY

The John P. Gorman Coal Co., Lexington, has purchased the property of the Hazard Elkhorn Coal Co., at Sandlick, in Letcher County. The company on May 1 bought the Elk Creek Coal Co. property at Blackey, in Letcher County. The Gorman interests have announced that they planned to materially enlarge the capacity of the Hazard-Elkhorn plant.

According to word reaching Williamson, W. Va., from the Pond Creek mining section of Kentucky, the mines operated by the Henry Ford interests have been closed down and will remain inactive until organizers representing the United Mine Workers leave the field. The mines are operated on an open-shop basis, the scale paid being equal to that fixed by the union. Unsuccessful efforts were made to organize the Pond Creek section about the time the union sought to organize Mingo County miners. Organizers affiliated with the miners' union appeared in the Pond Creek section several weeks ago.

MINNESOTA

The Colorado Coal Corporation, of Minneapolis, has filed articles of incorporation, capital \$50,000. The incorporators, who are all of Minneapolis, are William J. Hughes, David and Rudolph Christie and Matthias J. Schoeffer.

OHIO

The Southern Ohio Coal Exchange reports for the week ended May 10 an output of 69,975 tons from 439 mines having a full-time capacity of 644,122 tons. This leaves a shortage of 574,147 tons. Labor shortage was responsible for a loss of 1,700 tons; strikes, 7,250 tons; mine disability, 2,110 tons and "no market" 562,011 tons. During the same week the eastern Ohio field ordered 9,930 cars and loaded 7,878 cars.

Suit has been brought by the Martin Ebersbach Coal Co. and the Peacock Coal Co. against the Great Lakes Coal Co. and the New Pittsburgh Coal Co. to collect \$450,000 alleged due on the sale of certain coal properties to the defendant companies in 1920.

C. H. Winefordner has purchased an interest in the Beverly Coal & Coke Co., a jobbing concern in the Atlas Building, Columbus, and has assumed with R. B. Beverly a part of the active management.

Noah F. Andrews has been appointed a deputy mine inspector by the Ohio Division of Mines and assigned to Hocking County. He resides in Logan.

OKLAHOMA

All union coal miners of the McAlister area and at Wilburton, Pittsburg County, are idle and the mines not in operation pending settlement of new wage contracts. Approximately 2,500 miners are idle in this district. Representatives of the miners and operators are in conference now and it is expected that new wage contracts will be signed in a few days.

PENNSYLVANIA

James L. Cooney, general manager of the Scranton Coal Co., was named president of the company by the board of directors May 23 to succeed Frank E. P. Latt, deceased. Mr. Cooney has been an officer of the company for about two years. He is widely known in anthracite mining circles.

An examination for certificates of qualification as mine foreman, assistant mine foreman and fire boss for the First, Sixteenth, Twenty-First and Twenty-Seventh Bituminous Inspection Districts was held in Turner Hall, Sixth Street and McKean Avenue, Charleroi, May 27, 28 and 29, 1924. The examining board was composed of the following: C. P. Byrne, chairman, Joseph Edwards and Michael Timlin, with Alexander McCand and W. H. Howarth as assisting inspectors.

At recent meetings of the Hudson Coal Co. general grievance committee efforts to call a general strike by alleged radicals in the ranks of the union proved fruitless. The grievances submitted are being adjusted by the company and the Conciliation Board.

Coal loadings in central Pennsylvania have been showing slight gains in May over April, which is regarded as the poorest month of the year. Up to May 17, 28,527 cars were loaded as against 24,366 for the corresponding period of April. Loadings of 50,000 cars are predicted for the entire month.

The mines of the Glen Alden Coal Co. flooded several weeks ago by the Lackawanna River are still being unwatered. Pumps are in operation at several shaft openings. It is estimated it will require at least another month to complete the work and prepare the mines for operation.

The Pennsylvania Coal Mining Institute is planning a big first-aid meet on the Cambria County fair grounds near Ebensburg. President W. A. Swift has appointed the following committee to consider the proposition and make a report at the next meeting of the institute, on June 20: T. J. Davis, John Reed, V. A. Stanton, D. Hopkins and T. A. Stevenson, of Johnstown; J. E. Cheynoweth, of Boswell; James Gatehouse, of Seward, and Isaac Rounsley, of Kelso. A committee composed of F. J. McKernan, George J. Playez and D. L. Boyle was named to obtain a larger and more suitable place for the meeting on June 20, when Floyd W. Parsons, formerly editor of *Coal Age*, will deliver an address.

John Brophy, president of District No. 2, United Mine Workers, has appointed Paul W. Fuller, of Pittsburgh, as director of education of the district. The union's department of education is a new departure and was created at the annual convention held in Altoona in March, last. Mr. Fuller entered upon his duties at the close of the State Federation convention in Allentown last week. For the present, headquarters of the new department will be in the district office building in Clearfield while Mr. Fuller makes a survey of every local in the district which consists of about 50,000 miners. The new department will co-operate with the department of education of the Pennsylvania Federation of Labor.

The Bethlehem Mines Corporation, with extensive operations at Johnstown, Heilwood, Wehrum and Slicksville, all in central Pennsylvania, and at Preston, W. Va., announces that, effective at once, the company's 5,400 miners will be placed on the 1917 scale of 72c. per ton instead of 92c.

Owing to a disagreement between operators and miners over the payment of a 10c. bonus on each ton of coal produced, the greater portion of the Broad Top coal field is closed, with every indication of a long period of idleness unless the union miners relinquish their bonus claim. The wage agreement was not signed by operators in the Broad Top region because the union refused to abolish the bonus, which, it is contended, the United Mine Workers pledged themselves to take out of the wage schedules in that district since April 1, 1918. The union has started to distribute relief and there is a general feeling of satisfaction among the miners.

Indications point to a long-drawn-out strike of all employees of the Lehigh Valley Coal Co. in the Pittston field. The district union officials have made it clear that they will have nothing to do with the strikers or their committees because of the fact that the walk-out is illegal. The company officials will not meet with the men until the collieries are working.

No improvement is observable in the Connellsville coke region. W. J. Rainey, Inc., has put out 300 ovens at the Allison plant, but is still working the Allison mines full. The Lincoln Coal & Coke Co. has closed 400 ovens at Keister, near Uniontown. The Consolidated Coke Co., near Masontown, has reduced wages to the 1917 scale.

Work has begun on the erection of 200 new homes at Shenandoah Heights and families are ready to occupy the houses when they are constructed. The tract is on a mountain over Shenandoah and was sold to the present owners by the Philadelphia Board of City Trusts, which administers the Girard Estate.

The Eastern Fuel Co., of Pittsburgh, announces the appointment of J. M. Gates as resident manager at Philadelphia in charge of sales in the Philadelphia and nearby districts of New Jersey, Delaware and Eastern Pennsylvania. The Prudential Coal Co., which was affiliated with large Canadian interests and with which company Mr. Gates was interested as vice-president, is liquidating its business in the United States. It is expected that the Eastern Fuel Co. will take care of the operating connections, as well as the old customers of the Prudential company. An addition to the sales force of the New York Office of the Eastern Fuel Co. is Edward C. Clark. Mr. Clark is a Yale graduate and a former resident of Boston. The resignation of H. J. Burkey, formerly of the Pittsburgh office of the Eastern Fuel Co., became effective May 10.

Announcement was made Saturday, May 3, of the purchase by the Hudson Coal company, of Scranton, of several lots in Carbondale, Pa., from William T. Carden, for \$14,000; and in Archbald from William R. Gilboy, for \$10,000. An unconfirmed report is to the effect that the land will be used for the erection of homes for colliery superintendents.

W. A. Chandler, formerly consulting electrical engineer of the Hudson Coal Co., Scranton, recently was placed in charge of all the engineering and construction work of the company, including the shops and laboratory.

James D. Sisler, associate geologist, Topographic and Geologic Survey of Pennsylvania, is in the coal fields of western Pennsylvania. During May and June he will study the geologic occurrence of various coal beds and investigate new methods of mining and the use and application of new mining machinery.

Charles F. Barrett has taken the management of the Buena Vista Coal Co., of Butler, with office in the Butler County Bank.

Mine No. 13 of the Pennsylvania Coal & Coke Co., at Hastings, Cambria County, has indefinitely suspended operations, due to the present depression. Employees of the mine are razing the tippie and the pumps and other machinery, which will be transferred to other operations of the corporation.

TEXAS

The State Board of Control of Texas, sitting at Austin, has awarded contracts to supply the various state institutions with fuel for the remaining portion of the fiscal year that ends on Sept. 30 to the McAlester Coal Co., of Dallas, and the Sparks Lignite Co., of Rockdale. Prices for coal average \$2.14 per ton, while the price for lignite is \$1.53 per ton.

The Texas Power & Light Co., of Dallas, has acquired lease on several thousand acres of land in Henderson County, near Malakoff, and is now testing this land to determine the extent of the lignite beds that underlie it. It is proposed to open extensive lignite mines, if the fuel is found in sufficient quantities, and to mine it for use as fuel in the company's electric-generating plants in Texas. A part of the electric company's development program also calls for the establishment of another great electric plant on the site of the lignite beds near Malakoff, and thus eliminate cost of haulage. The Malakoff plant will cost \$2,000,000

and it is planned to open sufficient mines to give employment to approximately 1,000 miners and other employees.

UTAH

The Union Carbide Sales Co. has lodged a complaint against the amendment to the safety code proposed for Utah coal mines which would require the use of electric lamps in coal mines. The company holds that not all coal mines in Utah are gaseous and that for this reason some of them are safe for the use of the open-flame lamp. It asks that the amendment be drawn to permit the chief mining inspector for the Industrial Commission to designate the kind of lamp to be used.

Eli F. Taylor, local U. S. land office registrar, will auction off 1,818.84 acres of coal land in Castle Gate district on June 18.

Production of coal in Utah in April was 325,195 tons, as compared with 286,352 tons in April a year ago and 255,319 in April, 1922.

The Utah Briquetting Co. has been formed and is applying for permission to sell \$50,000 worth of stock for financing the company. George W. Love, Mohrland, is president of the company and inventor of a process.

The Utah Oil Refining Co., of Salt Lake City, one of the largest oil-refining concerns in the West, has decided to go back to coal for use under its stills. Coal consumption will be 80,000 to 100,000 tons a year.

VIRGINIA

Directors of the Virginia Iron, Coal & Coke Co. voted May 22 to omit the regular semi-annual dividend on common stock. At a meeting in November last a declaration of 1½ per cent was made and a year ago a 2 per cent semi-annual dividend was ordered. The regular semi-annual 2½ per cent preferred dividend was declared, payable July 1.

The Chesapeake & Ohio Coal Exchange, of Newport News, Va., the last of the coal exchanges now in operation at Hampton Roads, will cease operation as an exchange May 31.

Clayton M. R. Wigg, Southern representative of the Houston Coal Co., has been elected president of the Hampton Roads Coal Club to succeed T. M. Bailey, resigned. T. R. Licklider, manager of the Norfolk office of the Trans Ocean Coal & Transport Co., was elected vice-president to succeed Mr. Wigg. Chester B. Koontz continues as secretary and treasurer.

Transporting Coal in China

Basket below ground, the backs of coolies and lumbering wagons on the surface make coal expensive in the Orient, despite cheap labor.

WEST VIRGINIA

The Richard Mine of the Bethlehem Mines Corporation was shut down indefinitely during the second week of May and about 140 men who have been working on a part-time basis were affected. So far as can be learned only the Masontown and Bretz mines of the company are now in operation. The understanding is that the 1917 wage scale has been put in effect at the mines still continuing in operation. Mines of the Bethlehem Mines Corporation on the Morgantown & Kingwood R.R. are operated on an open-shop basis.

Inn at Glen Rogers

Owned and operated for the benefit of employees by the Raleigh-Wyoming Coal Co., Glen Rogers is in Wyoming County, West Virginia.

The body of George Holliday, Sr., mine foreman, has been recovered from the Benwood mine. Further exploration brought to light another body—that of an unidentified miner. In all 119 miners lost their lives in the explosion which wrecked the mine, on the morning of April 28.

The West Virginia Super Fuel Co. has just been organized with a capital stock of \$400,000 to operate in the northern panhandle of West Virginia. The general office of the company for the time being is at Moundsville. The organizers of the company are A. R. Bice, of Bellevue; Ernest Fry, Stephen Steranchak, and J. R. Dorsey, of Pittsburgh, Pa. and H. S. Allshouse, of Irwin, Pa.

The Three Fork Coal Co., of Ellamore, is installing an up-to-date screening system in addition to building a large number of houses for miners, a storehouse and a club room. This company has been mining nothing but run of mine coal heretofore but having learned that the coal under careful mining and preparation will screen about 75 per cent lump, it was decided to install the necessary screening apparatus. Such a large percentage of lump is a little unusual for Sewell coal, but inasmuch as the coal comes within the area of the Deer Park anticline, it is unusually hard. About 20,000 acres of coal land are owned by the company.

Oren F. Kelley, representing A. J. Thompson, of Titusville, Pa., is in Elkins with a corps of men and is starting to open the Sewell coal on a tract of 2,000 acres near Woodrow, in Randolph County. Present indications point to the existence of several hundred acres of high grade Sewell coal underlying the property, averaging about 40 in. in thickness, there being one other vein of good coal.

Operations have been resumed at the Pursglove mine of the Connellsville By-Product Coal Co., on Scotts Run, after a short suspension. This mine is owned by the Paisley interests, of Cleveland. This is a union plant but was shut down for a time pending agreement on a new wage contract. About 300 men are normally employed at this time.

A loss of about \$35,000 was sustained when the store building of the Booth Supply Co. at the Riverseam mine of the H. J. Booth glass interests, of Pittsburgh, was destroyed by fire. A cold-storage plant operated in connection with the store also was destroyed.

Fire early in May destroyed tipple No. 5 of the Raleigh Coal & Coke Co., entailing a loss aggregating several thousand dollars. The fire was of unknown origin. Although the mine had not been in operation since July, 1923, several men including a watchman have been kept at work in order to keep the equipment in shape. The No. 5 mine is located between Beckley Junction and Beckley.

Although hardly more than a year old, the mine of the King Fuel Co., of which A. J. King, of Huntington, is the head, has attained an output of 1,800 tons a day.

WISCONSIN

Construction of a modern coal dock at Superior, Wis., to cost at least \$750,000 was announced by the Reeves Coal & Dock Co. May 20. The new structure, to be electrically operated, will replace the wooden dock now being dismantled. Permission to extend the shore line, granted by the United States Engineer's Office, will provide the dock with 150,000 sq.ft. additional storage space. The Reeves property, 23 acres in extent, is one of the best sites on Superior Bay. Work on the new dock is expected to start as soon as the old one is torn down.

CANADA

Briquetting of Saskatchewan lignites as the lignites of the Dakotas, are now being briquetted, is proposed by the Lignite Utilization Board, supported jointly by Saskatchewan and Alberta. The board has just reported that it has developed a successful method and is asking for an additional appropriation so that it may demonstrate the process to convince capital that the scheme offers a good investment. The

board wants to run its plant longer so as to determine exactly the cost of materials, labor, repairs, replacements and technical supervision and control.

Coal production in British Columbia for April totaled 144,205 tons, a decrease of 58,725 tons from March. This is explained by the lack of output in the Crows Nest Pass field, where a strike is in progress. In March the Crows Nest district produced 69,007 tons. April figures show that the Vancouver Island coal mining industry is improving. The output of the Canadian Collieries (D), Ltd., improved by 3,398 tons, that of the Western Fuel Corporation by 5,538 tons, and other collieries advanced to the extent of 2,060 tons. In the Nicola Princeton field, however, there was a slight drop of 714 tons.

Major S. J. Robins, and Captain Henry Davies, both of Cardiff, Wales, representing a syndicate of Welsh coal operators, have spent some months inspecting coal properties in Alberta. They are now on their return journey to England to report to their principals who have in view the development on a large scale of the Western coal fields for supplying eastern Canada. Major Robins and Captain Davies have purchased extensive coal areas for the syndicate from individuals and small companies not having sufficient capital to carry on development.

A noticeable improvement in the Cape Breton coal trade is reported. All the British Empire Steel Corporation collieries in Cape Breton except the Jubilee are working with good outputs and shipments to Montreal are in full swing. There has been considerable activity at Louisburg with several bunker steamers as well as cargo steamers in port.

Charles Camsell, Deputy Minister of Mines for Canada, and Thomas Molly, Minister of Industry for Saskatchewan, have been appointed to the Lignite Utilization Board.

Industrial Notes

The following executive changes were made in the **Timken Roller Bearing Co.**, effective May 1: George C. McMullen, formerly manager of sales of the industrial bearings division, became district manager of sales of the Timken interests on the Pacific Coast, with headquarters at San Francisco, Cal., and Harry H. Gildner, formerly in charge of the Chicago office of the company, became manager of the industrial division with headquarters at Canton, Ohio.

The Pittsburgh office of the **Sullivan Machinery Co.**, which has for many years occupied quarters on the fifteenth floor of the Farmers Bank Building, moved April 1 to larger space and now occupies rooms 517-520 in the same building. William R. Jarvis has been the company's Pittsburgh manager since 1904.

In connection with the opening of a mine at Calvin, Va., by the **Blackwood Coal & Coke Co.**, of Blackwood, Va., the company will have a large tipple with revolving dump and reinforced concrete storage bins of a capacity of 2,500 tons. The contract for the construction has been awarded the Roberts & Schaefer Co. of Chicago.

The Canadian budget, just presented, should have far-reaching benefits to manufacturers of machinery in the United States. The duties have been considerably reduced on coal-washing and coke-making machinery and on mining machinery and equipment.

Traffic News

Ohio Collieries Co. Alleges Discriminatory Rates

Alleging discriminatory freight rates the Ohio Collieries Co., of Toledo, lodged a complaint against the Hocking Valley Ry., with the Ohio Public Utilities Commission. The complaint asks that the commission determine a rate which will place the Ohio Collieries Co. on an equal basis with companies operating in the Pomeroy fields and in West Virginia and charges that rates to Columbus over the Hocking Valley line now give these companies an unfair advantage.

The Ohio Collieries Co., it is stated in the complaint, operates coal fields near Poston, Ohio, whence shipments are made to Columbus over the Hocking Valley Ry. Keen competition exists in this Columbus market between companies operating in the Pomeroy fields and the complaining company, it is charged.

That, to Columbus, on its line, the defendant maintains and assesses a common or group rate from all shipping points, is an allegation made in the complaint which charges that the Hocking Valley company collects a "discriminatory and therefore unlawful rate" on bituminous coal from the Hocking district to Columbus.

Obituary

Frank E. Platt, treasurer, vice-president and acting president of the Scranton Coal Co., died at his home in Scranton, Pa., May 13, aged 65. Death was due to heart disease. Mr. Platt came of a family of early settlers in Scranton. With his brother-in-law, Joseph H. Scranton, and Sanford Grant, J. Curtis Platt, father of Frank E. Platt, established the first steel and rolling mills and blast furnaces in Scranton. After graduating from Rensselaer Polytechnic Institute, Troy, N. Y., Frank E. Platt, engaged in the iron business. He gave his entire attention to the management of the blast furnaces. Mr. Platt served for a time as director of the Moosic Powder Co., the Weston Mill Co., the Rivoton Mills Co., and other companies. Since the organization of the Scranton Coal Co., he was active in official capacities for that organization.

Association Activities

The board of directors of the Central Pennsylvania Coal Producers' Association has named a committee of twenty-one to act as an advisory board to the members of the association. The committee is divided under three heads: mining methods, machinery and power. The work of these committees will be to furnish information to the members of the association upon these subjects which would otherwise require considerable individual time. Following are the committees: Mining methods—A. B. Crichton, Johnstown, chairman; Fred Vinton, Indiana, vice chairman; C. D. Oldknow, Du Bois; R. W. Austin, Clearfield; C. L. Patterson, Robertsdale; William C. Faulk, Elbon; J. W. Stephenson, Hastings; Malcolm Mc-

Dougall, Sonman; Thomas L. Jones, Altoona, and S. T. Brown, Indiana. Machinery—L. W. Householder, Indiana, chairman; Richard Peale, St. Benedict, vice chairman; R. V. Williams, Bethlehem; Fred Norman, Kittanning; C. J. Hamilton, El Mora; Robert F. Roth, Altoona, and F. D. McBellis, Gallitzin. Power—E. K. Davis, St. Benedict, chairman; A. S. Wilson, Johnstown, vice chairman; E. E. Hewitt, Indiana, and James M. Cook, Johnstown.

The West Kentucky Coal Bureau, holding its monthly meeting in Louisville on May 13, re-elected C. W. Taylor as representative of the association on the Board of Directors of the National Coal Association, and heard a report from M. B. Lanier, representative of the National Coal Association, to the U. S. Chamber of Commerce meeting in Cleveland the previous week. A communication also was read from Secretary Hoover concerning summer stocking of coal.

Coming Meetings

American Wholesale Coal Association. Annual convention, White Sulphur Springs, W. Va., June 3-4. Secretary, G. H. Merryweather, Chicago Temple Bldg., Chicago, Ill.

West Virginia Coal Mining Institute. Annual meeting June 3 and 4, Elkins, W. Va. Secretary, R. E. Sherwood, Box 1026, Charleston, W. Va.

The National Foreign Trade Convention. June 4-6, Boston, Mass. Secretary, O. K. Davis, 1 Hanover Square, New York City.

National Retail Coal Merchants' Association. Annual meeting, Hotel Virginian, Bluefield, W. Va., June 4-6. Secretary, Walter D. Rogers, Transportation Building, Washington, D. C.

Southwestern Interstate Coal Operators Association. Annual meeting June 10, Kansas City, Mo. General Commissioner, W. L. A. Johnson, Keith & Perry Bldg., Kansas City, Mo.

Illinois & Wisconsin Retail Coal Dealers Association. Annual meeting, June 10-12, Delavan, Wis. Secretary, I. L. Runyan, Great Northern Bldg., Chicago, Ill.

Illinois Mining Institute. Annual meeting, June 12-14 from St. Louis via boat down the river. Secretary, Martin Bolt, Springfield, Ill.

Midwest Retail Coal Association. St. Louis, Mo., June 17-18. Secretary F. A. Parker, St. Louis, Mo.

American Society for Testing Materials. annual meeting, Chalfonte Hotel, Atlantic City, N. J., June 23-27. Secretary, Edgar Marburg, University of Pennsylvania, Philadelphia, Pa.

American Institute of Electrical Engineers. annual convention, June 23-27, Edgewater Beach, Chicago, Ill. Secretary, F. L. Hutchinson, 29 West 39th St., New York City.

First International Management Congress. Prague, Czechoslovakia, July 21-24.

World Power Conference. Wembley, London, England, June 30-July 12. O. C. Merrill, Federal Power Commission, Washington, D. C.

New Equipment

New Reflector for Highly Concentrated Light

For use in industrial operations where highly concentrated light over a limited area is desired, a new reflector has been developed by the Westinghouse Electric and Manufacturing Co. It has been designed to give maximum light distribution from a 25- or 50-watt mill type lamp, insuring intense illumination. In such work as coil winding, machining, planing, drafting and any other operation requiring accurate vision, it is particularly suitable.

The body of the reflector is a one-piece steel stamping covered with a ground coat of fired porcelain enamel and a finishing coat of white enamel. It is provided with a brass holder so that it may be fastened to a brass-shell socket without other support.

Reflector Intensifies Light Over Limited Area

In buildings where there is considerable vibration the use of mill type lamps has greatly increased. This reflector has been designed to obtain the maximum possible light distribution from a 25- or 50-watt mill type lamp.

Headlight Built to Sustain Bumps on the Road

A mine locomotive headlight possessing a number of improvements over previous designs has been developed by the General Electric Co. This light is of especially rugged construction to withstand rough usage.

The frame incloses a simple focusing mechanism which adjusts the lamp to the focal point of the reflector by a horizontal movement of the socket. Heavy door pins, hinges and guard grids add to its ruggedness. The leads enter through water- and moisture-tight stuffing boxes, and the lead itself is covered with soft but durable rubber, thus insuring a tight joint. The general contour of the unit is such that blows from falling objects glance off without doing any damage. The casing is supported on springs and spherical headed studs, permitting universal movement.

The glass door is recessed in the casing, and is protected by a grating heavy enough to withstand severe shock in case of collision. The glass itself

Headlight for Mine Service

Manufacturers are now giving more and more consideration to adverse mine conditions. Here is a headlight designed particularly for mine locomotives. It is claimed it will withstand severe shocks without damage.

is reinforced with wire. Both the door and mirror reflector are cushioned with tarred rope for the dual purpose of insuring the interior against dampness and of affording some degree of resiliency in case of shock.

The reflector is of heavy glass, silver-plated and copper-coated to protect the silvering and strengthen the mirror.

Fifteen-Ton Dump Car Cuts Strip-Pit Costs

One of the biggest types of dump cars used anywhere in coal mining is the 15-ton car recently put into service by the Penova Coal Co., at its strip pit in Adena, Ohio. This company, backed by such experienced coal strippers as Grant Holmes of Danville, Ill., who has been actively interested in stripping for 40 years, decided the average 4-yard dump car was too small and also that an automatic dumper was

needed in order to reduce costs. The Western Wheeled Scraper Co. of Aurora, Ill., manufactured the 15-ton car shown herewith to meet these requirements.

This car handles fully four times as much coal as the average 4-yard car; it is a double truck, one-way, air-dump, self-righting car built for 36-in. gage track. The dumping angle is 35 degrees. This, the operators think, reduces breakage of coal as it is being discharged. The double truck feature reduces the spillage along the track because it produces good riding qualities.

Two cars are spotted at a time and are dumped by a man below who directs the loading of a conveyor belt. He pulls a cord which lifts a trigger on the cars' air dumping mechanism. The two cars discharge their loads, right themselves automatically, and are pushed ahead.

Well Balanced Air-Compressor

A new design of single-stage centrifugal compressors, has been perfected by the General Electric Co. and is now on the market. The new compressors are of two types, single- and double-inlet. The single-inlet type is designed for general use; the double inlet type being necessary when the ratio of impeller inlet and exit diameter reaches a value demanding its use.

The machines are available in capacities of from 500 to 75,000 cu.ft. per min. at 0.75 to 6 lb. pressure. They are provided with oil pumps designed to furnish plenty of oil to the bearings. Capped holes in the tops of bearing linings are eliminated, thus preventing dust from entering the lubricating system. A heavy hinged cast iron cover is provided on one side of the middle bearing bracket which may be lifted to inspect the return flow of oil from the lubricating system.

The pulsation point of these machines occurs at very light loads. The

Motor-Driven Air Compressor

Unit construction makes it possible to design this compressor so that it vibrates only slightly at very low speeds.

efficiency curves are very broad, thus showing an improvement over older types. The no-load power consumption is between 60 and 70 per cent of that required for previous machines.

Outstanding construction details include bearing supports of strong construction, the casing being attached to the bearing bracket by a flange. The weight of the casing, although not great, has been distributed in such a manner as to make the unit mechanically strong. This is made possible by the use of steel plates varying from $\frac{3}{8}$ in. to $1\frac{1}{2}$ in. in thickness in the various parts of the compressor.

Fish Plate Holds Rail and Tie in Position

The illustration shows a fish plate or splice-bar which can be used with most track ties. It is made from a single piece of sheet metal and at each of its upper corners are laterally projecting lugs formed by cutting the metal and bending the free ends as shown. These lugs are located so that they project into and through the rail bolt hole.

At the bottom of the vertical section is a laterally extending base or flange which conforms to the rail flange. Extending downward near the ends are lugs which are formed by cutting away part of the metal. These two lugs are spaced so that the fish plate straddles the cross tie and locks it in position on both sides. This plate not only holds the rails together, but holds the ties in position. No special tools are necessary for its adjustment and no bolts and nuts are required. It has lately been put on the market by S. M. Casterline of Crafton, Pa.

Splice-Bar Performs Two Functions

When used with a suitable cross tie, this fish plate assists in holding the rail ends together and secures the tie in position.

Large Dump Car for Coal Stripping

This 15-ton car was built for the Penova Coal Co., Adena, Ohio, to speed up the output and help reduce the cost at the company's big strip pit. The air mechanism shown under the side of the car dumps and rights its automatically so that no employee need go onto the tippie.

Number 23

Negative Minds

PROGRESS in industry has in all branches and at all times been held back by conservative minds. Many men resent "being shown," and as a result no new method of operation is successful till enough have so tried it, proved it and profited by it that the men with negative minds find its adoption the only possible means of defense against their more aggressive and less negative rivals. A generation that has learned to fly, that has superseded the horse, that talks with wires and by wireless, that does nearly everything by machinery has no occasion to be negative. With everything changing and being changed there is no reason to take the attitude that the way of the past is the wise way, that something cannot be done because, forsooth, hitherto it has not been done.

After Waiting Six Thousand Years

IN THE year 4000 B.C. clay pipe was used in Babylonia. It may have been used even earlier. Yet it is only in the last few years that we have been able to attain the jointless pipe. Many operating men still remember the pneumatic undercutter. It was a hard machine to handle and its capacity was limited. It doubtless deserved to die, but that demise was greatly hastened by power loss on the line. Where we have low voltage today we had low pressure then. If only we had been able to establish good joints from mine to face the compressed-air puncher would have fallen into disuse less rapidly. If oxy-acetylene welding had come just a little earlier the air puncher would have stayed a decade longer. There are still many compressed-air lines in mines and it would seem that those who have them should weld them with oxy-acetylene. Thus most air would not be lost in transmission, the machine receiving the pressure of air with which it is designed to operate.

Conveyor in Stripping

GOING over the past history of stripping as printed in this week's issue we have an opportunity to review the various methods by which stripping may be accomplished and are led to question whether the full revolving steam or electric shovel is the last word in stripping. Is it certain that the dragline and conveyor do not have their place where stripping to greater depths than 40 ft. is justified by greater thickness of coal or even in shallower strippings?

That these projects gave way to the present-day large capacity shovel is no evidence perhaps that it was the only practical machine in the then existing state of the art. We are constantly getting new materials of construction and perhaps what was impossible then may be possible now. Just as the airplane was a failure till we developed the internal-combustion engine, so today we may have advanced to such an extent in the

art of dirt removal, in the materials of construction and in mechanical control that some of the equipment with which success was impossible in the nineties and in the first decade of the present century might be made feasible today. The suggestion awakened by Grant Holmes' reminiscences published this week and last is worthy of thought. Surely stripping has not reached its limit as to depth and operating methods. A slight increase in depth would greatly widen the field of its applicability for large areas lie under cover too deep for present equipment, and the deeper the coal the better its quality.

An Excess of Technical Men

MUCH has been said of the excess of workers in the coal industry and what has been stated cannot well be controverted, though most sections would like to have more men, for they have room for them in the mines. However, the men now employed can flood the railroads with coal and cannot find market enough to keep them continuously at work.

Of technical men, however, we really have a dearth, but they are so little appreciated by the operating forces that there are many of them without jobs. Operators cannot understand that only proper control of operations will produce cheap coal. The most expensive mine is one that is undermanned in its management, its safety, mining, mechanical and electrical forces. Without the needed officials, accidents hamper production, explosions destroy both human life and the mines themselves, machines fail to work steadily and efficiently and the repair bills are enormous. No one can leave the mines with economy and safety to the operation of blind chance and incompetent or insufficient direction. Anything that is worth doing is worth doing well.

Keep Goodwill with Your Neighbor

NO INDUSTRY can afford to neglect its public relations. It is a losing game that is played against a combination of players. No industry knows just when it will have an important message for the public, some condition in its operation it desires to establish for its own well-being. When that time comes it will be well if it has the ear of the public rather than its boot. If the public is convinced of the disinterestedness of the industry much success will be attained in meeting its just ends. A poor way indeed it is to show no interest in a neighbor till you desire to borrow something or to ask for a favor.

Much can be imposed on any one or on the public, we can hold ourselves proud and unapproachable, so long as others must accept our conditions but when a favor is desired that perhaps will hurt no one, we have no friends who are willing to bestow it and the service is withheld. The coal industry should beware of this.

When the sun shines and everything is going well between ourselves and our neighbors it is good time to establish friendly relations. Today, prices are low, labor troubles are temporarily at an end, coal is plentiful, no one ventures to ship poor coal, the miners are compelled to keep the coal clean, the snowbirds have disappeared, now is the time to cultivate good relations and to plan some way by which those friendly relations may be maintained.

Simplification of Sizes

SOME have contended that the reason why anthracite is sold in so many sizes is because an unhappy necessity in the cleaning of coal made meticulous sizing essential. Perhaps the real cause was a desire to make an even and therefore a handsome product; but whatever was the reason the fact remains that more sizes are being made than the public really needs.

A few would have served just as well had not the operators, by putting them on the market, developed the desire for every one of the many sizes and made it difficult to amalgamate any without evoking public clamor. Some companies have found it necessary in the jigging of coal to prepare two sizes of chestnut but they had sense enough to mix the sizes after they were made. The lesson had been learned, but too late unfortunately for the elimination of other unnecessary sizes.

One method of washing is based on the flotation of coal in a medium of a given specific gravity. It works equally well on coals of any size, eliminating the necessity for careful sizing. But as coal is sold in many different sizes, that extremely valuable characteristic is left almost entirely unutilized. The operator with the mixed product must go to the expense of preparing his coal so as to afford the many sizes which an uninstructed public now demands.

The Illinois region also has developed a demand for close sizing. It makes several sizes and many mixtures of sizes and all to no purpose. This misfortune the operators of Illinois have called down on their own heads. They are utterly without justification.

A new coal-cleaning machine recently has been developed and introduced into West Virginia. It requires the most careful sizing. It would be deplorable folly if this size making resulted in educating the public, burning West Virginia coal, to demand a closely sized product. Rather than allow this habit to grow the operators who may install and use this machine should mix the product so as to obtain only those sizes which the public is accustomed to receive, thus doing their part to prevent demands for excessive sizing. The marketing of many sizes inevitably results in an inequality between their production and sale. This is harmful to the man who does not have the particular proportion of sizes that his trade is demanding, for he wants to move all his coal and not merely a part. Many sizes also involve a multiplicity of bins and loading tracks and all manner of trouble in loading.

A campaign of education is what we need. Simplification in sizes in certain cleaning operations may not be possible, but a simplification in selling is within reach. Here is an opportunity for an active coal-trade body or for the big father of all—the National Coal Association. Why let an unhealthful condition be perpetuated.

More Power to Him—And Less

FRANK FARRINGTON is no fool. Neither is he short of nerve. This president of the Illinois miners has proved those two facts before and he proved them again at his state convention the other day. He rose before his thundering thousand—some of them red-necked radicals ready to fight him at the drop of the hat—and stated some plain and unpleasant truths. He told his men that the industry is in a mighty bad way, and why. He told them some things they can and must do about it, and what he said was not all a pæan of praise for the domination of the industry by the United Mine Workers.

"I do not expect any outburst of applause," said he, and he got none. But he sent his men home thinking. Thus he performed a real service to the industry even though his schemes for curing coal's ills were not all sound.

Of course, Mr. Farrington's plan to provide work for workless miners by creating a great power-producing system in the coal fields of Illinois, burning Illinois coal to make electricity for the Midwest, is unsound. Not even Mr. Farrington himself can regard it seriously in his heart. If the miners, producers, consumers and state of Illinois were to build co-operatively enough power plants on the Mississippi and Ohio rivers adjacent to the state's coal fields to provide mining work for the 100,000 Illinois miners, enough power would be generated to supply practically the whole of the United States. How could it be sold within the 200-mile transmission district? Who would finance so vast an enterprise? And how many years would elapse before it could operate?

If the Illinois miners were to cling to their present rate of wages, which is assumed, does Mr. Farrington think Illinois coal could be used exclusively in his proposed power zone? It isn't so used now. Approximately 30 per cent of the total power consumption of the nation is within the range of Mr. Farrington's dream-power system, yet cheap non-union coal is hauled in to generate a great part of that 30 per cent. Does Mr. Farrington imagine his public-owned plants could run so much more economically than the great private plants of the Midwest that the spread between union and non-union fuel costs would be counterbalanced?

Farrington is no fool. He knows the truth of these things. He knows that the labor costs of Illinois coal must be reduced. Being the miners' leader he knows he cannot suggest it. He would be committing political suicide. The demand for reduction must come from the rank and file. So the best that the Illinois leader can do is to make his men realize the impossibility of their present position by giving them the cold facts of non-union competition, as he did, and then propose some such fantastic thing as his co-operative power plan as the only alternative to a wage cut.

The miners will soon perceive the futility of the power plan. Mr. Farrington hopes they will also perceive that he has done everything he can to save them. Then they will be ready to talk wages. More power to Farrington's wage plan and less to his power plan. Central power stations should be erected at mines but in moderation and as opportunity is presented. We must generate power for the present market as determined by a careful survey. Wild hopes that discount the future can help neither operator nor mine worker.

Freezing Process Enables Lessees to Sink Shafts in Deep Marsh Land of North Belgium

Forty-Six Beds Aggregating Over One Hundred Feet of Coal Made Almost Unapproachable by Bogs Thousands of Feet Deep—Shafts Sunk With a Protecting Ice Wall.

BY MAURICE BIQUET

Engineer, A.I.L.g.
Hensden, Limburg, Belgium

UNUSUALLY rich is a coal basin recently discovered in the northern part of Belgium. The entire thickness of the coal formation is probably not less than 2,000 m. (6,560 ft.) and will possibly attain 3,000 m. (9,840 ft.), but authorities are not yet agreed on these figures.

Forty-six beds are actually known. Their total thickness, in coal, is about 36m. (118 ft.), the average proportion of coal to the measures which contain it being from 2 to 4.1 per cent.

The average thickness of the layers is about 0.80 m. (2.62 ft.). The volatile matter in the coal varies from 6 to 42 per cent. Unfortunately, the rich portions are found to be covered by stagnant marshes, the thickness of which varies from 460 m. (1,509 ft.) in the eastern part of Belgium to 690 m. (2,263 ft.) in the actually prospected western portion. This makes it difficult to develop this coal basin, for any shaft that may be sunk must penetrate these great thicknesses of marshland, which consist for the most part of sand and wet marl. It has been possible, however, to overcome these difficulties by means of the freezing process, which consists in isolating a portion of the strata from the mass of surrounding marsh by means of an ice wall of approximately cylindrical form. In the center of this cylinder a shaft protected by the wall of ice is excavated.

SOLIDIFY RUNNING BOGS BY REFRIGERATION

To form this wall a number of bore holes about 1 m. (39½ in.) apart are drilled on the circumference of a circle concentric with, and of larger diameter than, the shaft to be dug. In each of these holes is lowered a vertical pipe sealed at the lower end. In this an extremely cold solution of salt is circulated. Around each pipe a frozen zone is formed that continues to widen until it unites with the frozen zones of the two adjoining pipes.

Preliminary to the initiation of the freezing process a careful study is made of the strata to be penetrated: (1) With regard to their nature because the freezing is transmitted differently in different strata, (2) in respect to the water in the strata encountered, which may be standing or gushing, and either fresh or of

varying degrees of salinity, and (3) with regard to the permeability of the surface layers. From this last consideration it is possible to determine whether a foreshaft should be excavated. A foreshaft presents certain advantages: (1) A reduction in drilling, (2) a diminution of the cold necessary, for that part of the shaft that is driven without freezing, (3) a saving

resulting from the greater facility of work at the surface, the distributing equipment for the brine being placed in this foreshaft. It presents at times some great inconveniences, for the inflow of surface water interferes with the work.

The number of borings depends on several factors, notably on the depth to be frozen. These factors influence the size of the circle along the circumference of which the holes are to be drilled. The number of

holes also depends on the ease with which the earth can be frozen, for if the ground does not freeze readily the distance between the holes must be decreased.

The holes should be made as vertical as possible, so that the frozen area shall be throughout of a predetermined thickness, otherwise there will be places where the shaft protection is inadequate. Different devices have been designed for the purpose of determining any deviation in the borings. The one that, at the present time, has given the best results is a teleclinometer invented by M. Denis, of Paris.

Through the indications given by these instruments it is possible to determine the horizontal section of the drilled area at all points in its depth. One can learn from these sections where, in order to prevent breaks in the protecting wall, it is necessary to make additional borings.

The freezing pipes must be made of a metal capable of resisting the changes in temperature to which they are subjected. Care must be taken to provide the pipe with tight joints.

In calculating the necessary thickness of the ice wall, the nature of the strata must be carefully considered, as it may be sand and moving gravel, or a chalk formation with extensive fissures. In such strata as these the ice plays the rôle of the mortar in concrete. As the ice in this instance receives the full compressive stress the wall should not be submitted to a pressure exceed-

WHEN WATER AND SAND CONSPIRE

MANY of our shafts have to be sunk in river bottoms where water and sand make caissons advisable. However, the depth of the shifting strata may be so great that the air pressure will exceed human endurance. In that event the caisson method cannot be adopted, and solidification of the ground is the only alternative. Cement has been used but in stubborn cases refrigeration is "indicated" as the doctors would express it. Mr. Biquet in this article describes the sinking of two shafts by refrigeration nearly a mile deep.

ing 20 kg. per sq.cm. (280 lb. per sq.in.). On the other hand in compact formations, the ice serves only to calk the fissures and the rock itself must support all the weight. This explains why with rock the thickness of the frozen ground may be reduced considerably.

The freezing is not transmitted uniformly along the freezing tubes. The theory of M. Lebreton proves that, other things being equal, the cross-section of the ice wall formed around the pipe will assume the shape of an erect cone, of a cylinder or of an inverted cone, according as the depth to be frozen is equal to, less, or greater than the theoretical depth, which depends on the following elements: The thickness of the inner pipes, their diameters, the conductivity of the metal, the quantity of salt solution in circulation at any time, and finally, the specific heat of the brine. Inversely, the depth being given, the form of the ice wall will depend on the elements that have just been enumerated.

With the aid of Lebreton's theory, the shape of the ice wall may be calculated. Consequently, knowing the quantity of water contained in the ground (or assuming it approximately) the number of necessary units of freezing for the formation of this ice wall can be deduced; but it is necessary to remember that all the cooling does not result in the formation of ice. At each level the temperature decreases progressively from that of the natural ground to that of the brine returning in the freezing pipe.

Taking into account, also, the losses due to radiation in the brine pipe, between the central refrigeration plant and the shaft to be frozen, the total units of freezing that must be employed can easily be deduced. On ascertaining the length of time required to form the ice wall, we find the degree of refrigeration per hour that is required.

To ascertain whether the area to be excavated is completely enveloped by an ice wall a borehole is drilled in the center of the shaft. In this hole no freezing pipe is inserted. The variations in the level of the water in this borehole determines the progress of the refrigeration. Where water is found at several levels, the adequacy of the wall may be tested by using several concentric pipes, each reaching one of these levels, the interior one reaching to the lowest level of all. Each of these pipes, because of the watertight bottom at the bottom of the hole, manifests the tightness of the wall at the water level to which it extends.

The brine used is a simple solution of calcium chloride (CaCl_2), or of magnesium chloride (MgCl_2), having a density such that the saline solution without itself freezing will afford the degree of cold desired.

The refrigerating machines most commonly used are those that are based on the evaporation of a liquefiable gas, such as ammonia, carbon anhydride, sulphuric anhydride, or a methyl chloride, ammonia and carbon dioxide being those most generally used. The gases

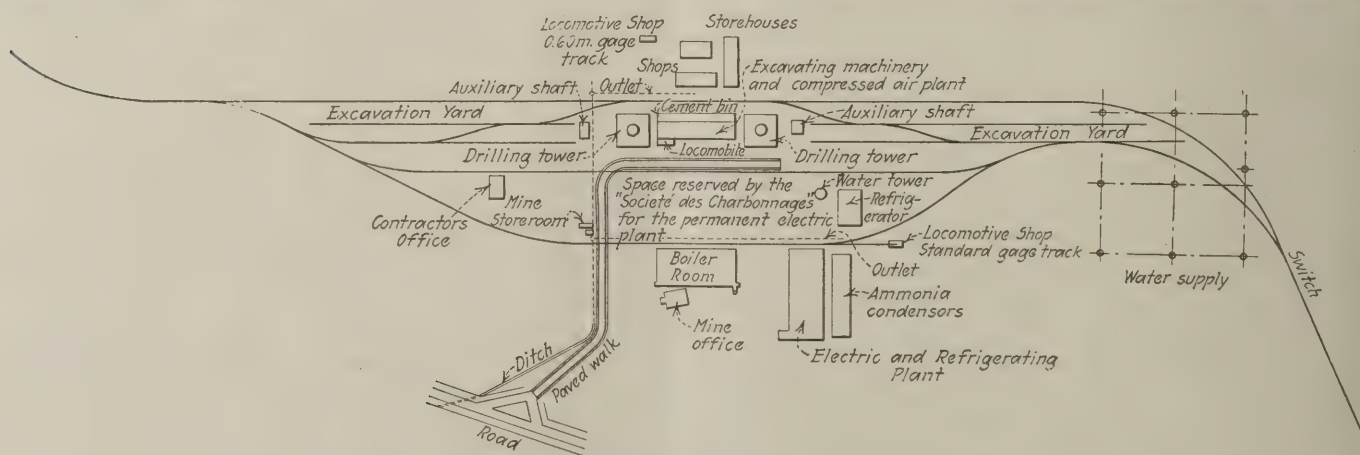

Fig. 2—Plant for the Sinking of Shafts by Refrigeration

The difficulty of putting down two shafts 2,034 ft. through ground artificially frozen, to say nothing of its further extension of 457 ft. through solid ground makes it necessary to build a plant merely for shaft sinking such as we, in America, would regard as quite elaborate if erected for the

final extraction of the coal. Belgian mine concessionaires face expenditures that in America would be appalling, but the richness of the coal deposits in northern Belgium is high enough to justify the cost; besides it must be considered that each concession contains about twenty square

miles and as each shaft is of large diameter it can accommodate a big output. It is evident that these unusual expenditures are required where the freezing must be carried to such extreme depths. Where the depths are less the expense is naturally less also.

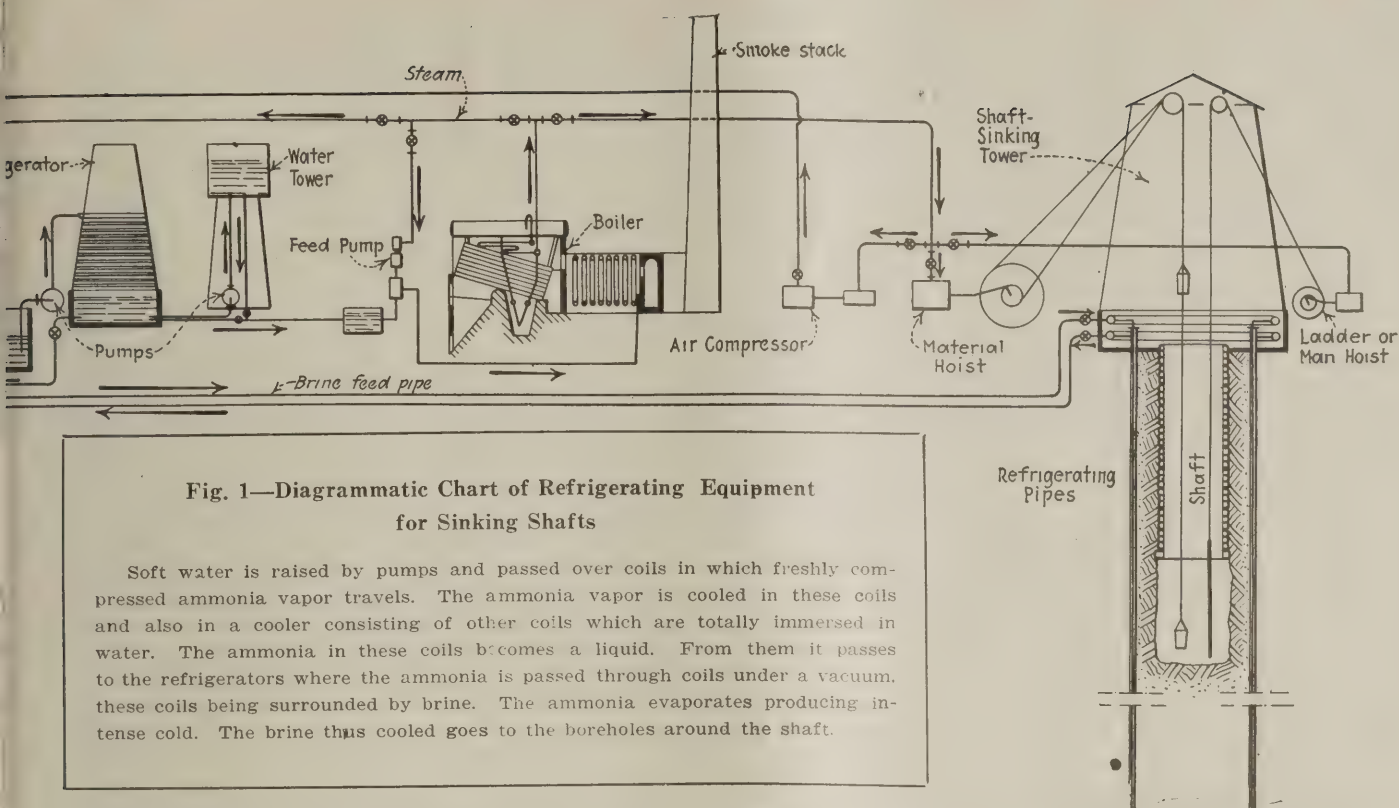

Fig. 1—Diagrammatic Chart of Refrigerating Equipment for Sinking Shafts

Soft water is raised by pumps and passed over coils in which freshly compressed ammonia vapor travels. The ammonia vapor is cooled in these coils and also in a cooler consisting of other coils which are totally immersed in water. The ammonia in these coils becomes a liquid. From them it passes to the refrigerators where the ammonia is passed through coils under a vacuum, these coils being surrounded by brine. The ammonia evaporates producing intense cold. The brine thus cooled goes to the boreholes around the shaft.

are compressed and then liquefied in the coils of a condenser which removes the heat of compression. These coils are kept cool by passing water over them continuously. The liquefied gases then pass through refrigerating coils over which the freezing liquids are circulated. The liquefied gases are vaporized in a vacuum maintained by the gas compressor. As they evaporate they create intense cold, lowering the temperature of the freezing liquids to the required degree. These liquids are used over and over again, so that all the heat they receive is that observed in passing through the boreholes which gradually reach their low temperature and cease to impart heat to them.

The Société de Fonçage de Puits Franco-Belge, of Brussels, is sinking two shafts in the coal-mining district of Helchteren & Zolder, each shaft being 790 m. (2,591 ft.) deep, of which 620 m. (2,034 ft.) is being frozen by a single current of refrigerating liquid. Fig. 1, shows the general arrangement; and Fig. 2 a plan of the installation.

It has been necessary to sink, for each shaft, 50 tubes arranged on the circumference of a circle, the diameter of which is 12.25 m. (40.2 ft.). Each of these tubes reaches down 620 m. (2,034 ft.). This, therefore, represents more than 60,000 m. (37.28 miles) of tubes, which means 60,000 m. (37.28 miles) of outside pipe of 113 to 128 mm. (4.4 to 5 in.) and an equal length of inside pipe of 50 to 60 mm. (2 to 2.4 in.) diameter.

The central freezing plant has seven units, each having two double-acting compressors driven by a compound condensing steam engine of 250 hp. The solution contains calcium chloride (CaCl_2) and has a density of 1.25. Nine electric pumps circulate the brine in the pipes, five of these pumps having a capacity of 150 cu.m. per hr. (660 gal. per min.), and four of 60 cu.m. per hr. (264 gal. per min.) at a pressure of 12 kg. (26.46 lb.), making a total of 990 cu.m. per hr. (4,356 gal. per min.). Each shaft requires a circulation of about

350 cu.m. per hr. (1,540 gal. per min.) so that some of the pumps can be held in reserve. The circulation pipes are combined in an ingenious fashion, in such a way that, by manipulating certain valves, the flow can be directed toward one shaft or the other.

Besides the seven refrigerating units, the central plant has two tandem compound condensing engines of 300 hp., each driving an alternator and a steam turbine, Zoelly system, of 500 kw. In another part of the plant is another engine driving an alternator of 100 kw. This represents a total electrical energy of 1,100 kw. Part of this serves to drive the electric pumps for the brine circulation, part is expended in circulating soft water for the condensers and part drives the warm water of condensation back to the Balke refrigerating plant. All this requires about 650 kw. The remainder is held in reserve. The boiler room contains eight boilers of the Bailly-Mathot type of 300 sq.m. (3,229 sq.ft.) heating surface, each. Five of these are generally in service, one is usually in process of cleaning, and two are held in reserve. The daily coal consumption when operating at full load varies from 66 to 72 short tons. Water is supplied by nine pipes sunk to a depth of 60 m. (328 ft.) from which the water is pumped. These are located 300 m. (984 ft.) from the plant.

The central air compression plant has two electric compressors of 100 hp., and four air compressors driven by steam engines and having capacity of 200 hp. The compressed air is used not only for the purpose of actuating the pumps but also to drive the pneumatic picks and drills for sinking the shaft. Each shaft has a compartment for hoisting excavated material, one for raising men, a service compartment and a compartment in which safety rope ladders are suspended. The hoist which handles the excavated material and shaft lining is a horizontal, duplex, non-condensing type of engine, controlled by a regulator, of American type. The principal dimensions are as follows: Diameter of

the steam cylinder 700 mm. (27½ in.); piston stroke 1,400 mm. (55 in.); diameter of brake flywheel 3,750 mm. (12 ft. 3½ in.); outside diameter of drums 6,800 mm. (22 ft. 3¼ in.).

One shaft was to be finished a year after the other. The freezing of the first shaft required seven months. The sinking and the insertion of lining took 21½ months or 567 working days. The average advance of the finished shaft per working day was thus 1.118 m. (3 ft. 8 in.), which is a veritable record for such a depth. The work goes forward rapidly after the ice wall is formed.

The freezing of the second shaft also took seven months. On April 10, 1924, of this year, after 401 working days, 451 m. (1,479 ft.) had been completed. The average advance of finished shaft per working day to this depth, was therefore 1.124 m. (3 ft. 8¼ in.).

The Société de Fonçage de Puits Franco-Belge, at Brussels, undertook to sink these two shafts to a depth of 790 m. (2,591 ft.) and of a diameter of 6 m. (19.68 ft.) as measured on the inside of the tubbing. The cost per meter, not counting the coal consumed in the boilers nor the price of the cast-iron tubbing, but including all other items, as for example, the boring of the refrigeration holes, the installation of the pipes, the freezing of the ground, the sinking of the shaft and the insertion of the tubbing, etc., is about 20,000 francs (\$1,177 par exchange) per foot. The weight of the tubbing of a shaft of 6 m. (19.68 ft.) in diameter and 620 m. (2,034 ft.) deep is about 20,000 tons. It may be added that these shafts are believed to be the deepest that have been sunk by freezing anywhere in the world.

Mine Management Should Furnish Data When New Tipple Is to Be Designed

BY ALPHONSE F. BROSKY
Assistant Editor, *Coal Age*
Pittsburgh, Pa.

COAL companies should regard the design and construction of tipples and the equipment they are to contain of sufficient importance to warrant them in providing operating data for their proper construction. Observation has shown, however, that a mine owner generally confines his activities to informing the manufacturers of tipples that he desires a certain type of structure and equipment. He almost never suggests their proper proportions. It would seem that by no means enough attention is given by the coal company to the future capacity of a new mine as measured by its tipple. In this statement I am not discrediting the ability of the tipple manufacturer who, as a rule, unquestionably knows his business and has the interest of his client at heart. I maintain, however, that the mine manager or his engineers should keep in closer touch with the builder and take a more active part in the actual design of the tipple and equipment than is usually customary.

The manufacturer and erector should have a knowledge of the coal to be prepared in order to properly design a proposed tipple. In order to determine the percentages of the sizes that the tipple is expected to handle—slack, nut, egg and lump—the coal is, in many cases, tested by hand methods. The conditions under which the coal is thus screened are not even similar to those existing in the tipple where shaker or other screens are employed. The person making such hand tests chooses coal from mine cars taken at random and screens it to obtain the percentages of the different grades. Who shall say that the samples chosen are representative of the mine output? In many cases they are not. If they come from near the outcrop, they, of course, will not be representative, and no matter how accurately the tests may be made the results will not represent the real mine output so far as the percentages of the various sizes are concerned.

In the dumping from the cars also, be they of either the endgate or solid-body type, the coal necessarily is broken and therefore the sizes of the coal in the car are not representative of those which the tipple will have to screen. In chuting coal, as well as in passing it through conveyors, the coal is broken more or less and the effect of this action in the aggregate may be

appreciable. Coal screened in hand testing is not broken up as much as when passed over tipple screens. For these and other reasons great care should be exercised in using or interpreting the results of hand tests.

When a tipple designer is called upon to draw plans suited to any particular operating condition or coal bed he may not possess absolutely accurate data. The mine may be opened in a new field upon which no basic figures are available. Even adjoining mines in a field already developed may furnish misleading data; perhaps the methods by which the coal is loosened at the face may cause an excess of fines. Another fact that the builder lacks is the percentage of refuse to be expected in the mine run. An assumed average is not a sufficient basis upon which to establish specifications for picking tables, which must be so designed as to handle the maximum quantity of refuse from capacity tonnage.

The correct width of screens may be easily ascertained, but it is more difficult to determine their proper length. The former dimension governs the tonnage capacity, while the latter regulates the thoroughness of size separation.

It is preferable to have a screen too long rather than too short. Fortunately, the builder usually arranges to avoid the latter. If the screen is too long, part of it may be veiled. An attempt should be made to obtain a screening area that will prepare the coal to the best advantage. When a new tipple is erected to replace an old one the company should be able to furnish many valuable suggestions to the builder as to the arrangement best suited to prepare the coal to be handled. It knows from its established trade what sizes are in greatest demand, and from the behavior of the old tipple it is able to advocate which unsatisfactory details in the first tipple should be eliminated and to suggest others which would be beneficial. Most important of all, it is familiar with the action of its coal in passing over screens; how long the screens should be and whether the openings should be oblong or round, also whether the screens should be plane or stepped, horizontal or inclined. The company officials should be in excellent position to specify the feeding arrangements best suited to the product handled.

This question should be subjected to detailed discussion. Certainly, the procedure to be followed by coal companies when planning and specifying a new tipple is important enough to warrant an exchange of ideas in an open forum. Only by such discussion is our sum total of knowledge increased.

Early Coal Stripping Full of Heartbreak—II

At Close of Last Century Butler Bros. Constructed Their Super Dragline—Experiments Were Made Later With Excavator and Conveyor—Finally, Revolving Shovel Establishes Stripping Industry on Firm Basis

BY GRANT HOLMES
Danville, Ill.

THE fair success attending the first machines used in light stripping led Butler Bros. to believe that a larger excavator would be a huge success. Financed by the Consolidated Coal Co., they began the erection of a monster dragline which would handle deep stripping, shale, soapstone and the coal. In 1900 the great machine was completed at a cost of \$30,000. Its massiveness required that it be supported on three 10-in. axles, each 22 ft. long. The center axle was geared to the engines, and the end axles were tied to the center one by side rods in locomotive style, giving traction to all six wheels.

One-hundred-and-thirty-five feet of horizontal boom supported by 60 ft. of vertical gantry frame made it necessary to weight the rear end of the machine with 25 tons of iron. Later on, after a fire, 20 ft. was amputated from the horizontal boom. Then it was difficult to keep the "giant" from tipping backward. Three drag buckets were used, each designed for handling one of the three materials encountered—dirt, rock and coal. The capacity of each was about 2 cu.yd.

Equipped with the new and supposedly capable machine, Butler Bros. started to clean off the remainder of the Missionfield coal. The first trouble encountered

was the immense weight of the stripper causing both rails and ties to be buried deeply in the ground, especially, those near the edge of the bank. This situation caused constant fear that the machine would slide down into the pit, and also was a cause of constant expense.

As soon as soapstone was reached, it was seen that the rock bucket was a rank failure, and a knife or sort of plow to cut into the hard material was attached to this "drag," but without success, as there was no way to hold it into the cutting. Drilling and blasting the work at a heavy expense were necessary if coal was to be obtained.

Coal loading with the machine was successful—twenty-five railroad "gondolas" could easily be filled in a day. But after two years of hard fighting to keep up their part of the contract with the coal company, Butler Bros. gave up the unprofitable business for a second time. This ended their efforts in Missionfield, and, discouraged, they left for other fields of endeavor.

Confidence in Butlers' machine to do the work was by no means shaken. Sixteen of their employees leased the dragline and accompanying equipment. This new concern, called The Salt Fork Coal Co., was a co-operative venture. For two years it operated with fair success, getting such coal as was not covered with hard material, but in 1904 the enterprise failed, a case of too many bosses spoiling the job.

While the co-operative Salt Fork Coal Co. was working, another firm was engaged in dragline stripping in a neighboring river valley. In 1903 a Mr. Donovan and

NOTE—First article appeared in the issue of May 29, pp. 797-800. Headpiece shows Butler Bros.' dragline drowned out. One of the frequent troubles in stripping is that it has to be done on flat land where the dangers of inundation are always imminent. Perched upon a weak bank with the water lapping it below and weakening the foundations such a heavy machine might conceivably pitch over the brink. At best, flooding impedes operations and muddies the coal.

Butler Bros. Last Dragline

In an effort to overcome the troubles caused by rock and thickness of overburden, this machine was built at a cost of \$30,000. It was supported on three 10-in. axles each 22 ft. long. The boom at first was 135 ft. in length. Its length made 25 tons of counter-weight necessary on the back of the machine frame to prevent upsetting.

some associates purchased a Schenable dragline and some stripping property in the Middlefork bottom near Missionfield. This dragline although much smaller than Butlers', had the advantage of being able to revolve in a complete circle. For nine months, these men attempted to strip coal, but river water constantly filled their cuts, and the wastebanks slid down so badly that no coal was taken out. Edward Gray then organized the Gray Coal Co., which bought the machine and property, but after five months of useless operation, gave it up in despair.

The "co-operatives" now made Mr. Gray manager and president of their company. Operations were carried on less than a year under the new management. Heavily in debt, the "co-operatives" again took hold of the work themselves, and for another two years they fought soapstone, repair bills and river water without success. Thus the financial rocks were struck for the third and last time. After nine years' work, only seven or eight acres of coal had been stripped at a cost approximating \$100,000.

The year 1907 saw the start of another strip mine the history of which somewhat resembles that of Missionfield up to this point. This was near Lily, Ky., in the Robinson Creek bottom, where a bed of coal 28 in. thick, lies under 6 ft. to 12 ft. of overburden. The seam is known as the Jellico. The first two companies to work at this pit had two steam shovels, one for stripping, the other for mining—built by the now defunct Vulcan Steam Shovel Co., of Toledo, Ohio.

A 2½-yd. dipper, 28-ft. boom and the mounting or railroad-car trucks, were the points of note on the stripper. The mining machine designated as the Vulcan "Little Giant" had a 1½-yd. dipper, a 22-ft. boom, and was mounted on traction wheels. Another interesting feature of this work was the use of an immense centrifugal pump to wash off the coal after it had been stripped. A few months' time convinced the operators that there was no money to be made with these shovels, so they discontinued the work.

A Monighan dragline was placed in this field in 1912, by the Ideal Block Coal Co. No better success attended

this machine than the others, so the company was forced out of business after two-and-one-half years' work.

In both Missionfield and Robinson Creek Bottom, steam shovels were first used, then draglines. A job in which both were operated in association, will be described. The Danville Brick Co. of Danville, Ill., owned a field adjacent to its brickyards, containing about four acres of coal under 25 ft. of cover. To strip off this much overburden, a small Vulcan steam shovel worked on top of the bed, dumping the spoil at one side. Moving parallel with the shovel, a small revolving dragline mounted on top of the nearest wastebank, picked up this spoil and deposited it in front of the machine. The dragline laid its own track, and did what the shovel could not do; it built wastebanks.

The coal from this mine was used in the company's plant, therefore, the question of whether reasonable profit could be realized on the strip pit did not enter so long as the cost of stripping and mining was below the market price for delivered coal. The Fall and Winter of 1912 and 1913 were occupied in uncovering this piece of coal.

To the southeast of Missionfield, about six miles, the same bed of coal lies within an average of 35 ft. of the surface. This shallow area contains about 70 acres, and the overburden consists of sand, gravel, loam and a heavy bed of shale. Here was a task for an extraordinary stripping machine, owing to the depth and composition of the covering. The dragline could have made short work of the soft materials, but shale was too much for it as was proven by the experiences of the Butlers at Missionfield.

The Consumers Coal Co. of Danville, purchased this field in 1904, and persuaded George W. Prutsman, an excavation contractor, to take the contract for stripping. The machine to do the work was built by the Bellefontaine Foundry & Machine Co. of Bellefontaine, Ohio, according to some of Mr. Prutsman's ideas, but the design and inventions were the work of George E. Turner. They had seen the failures of the dragline. Consequently they pinned their faith in the steam shovel, and instead of trying to use a long-boom shovel

as Wright & Wallace had done, Mr. Turner incorporated a belt conveyor with a shovel having a short-boom.

The advantage of this arrangement was that the shovel thus equipped with a short boom could dig rapidly, depositing the waste into a hopper that emptied on the conveyor, which operated at right angles to the digging, and carried the spoil to the dump. Four two-cylinder engines were required to operate this shovel, one for hoisting the 2-yd. dipper, a second for "crowding" it, a third for swinging the 35-ft. boom, the fourth running the conveyor which was 105 ft. long.

As with the old dredges in Missionfield, wood construction was used throughout. Four four-wheeled trucks supported the machine, giving a four-point suspension without attempt at keeping a level frame. The means of propulsion was by block and tackle. Like other steam shovels of its day, this could only dig forward, which meant that the circular plan of operation had to be adopted.

Work began in 1904—the stripping to be carried on

in the summer, the coal loading in the winter. After several attempts at getting the field in shape for circular operation, the plan had to be abandoned because of the irregularity of the coal area and the excessive depth of overburden that had to be removed in places.

The usable stripping consequently had to be opened in parallel cuts. This necessitated leaving the coal in the cut until the excavator could be moved back to the far end, ready to start on the next cut. "Moving back" usually occupied about two weeks' time. These parallel cuts were not straight, but contained many "inside" turns, that is, turns in which the dumping arc is smaller than the digging arc.

Where such turns occurred the immovability and length of the conveyor boom made its dumping end practically the center, the machine traveling around it for the length of the turn. Therefore, on such a turn the wastebank became so high as to clog the conveyor. Lengthening their stacker to 147 ft. did not aid conditions much, and only hastened the wearing out of the

Steam Shovel And Conveyor

George W. Prutsman and George E. Truner, in an effort to overcome the the obstacles that had defeated all previous stripping machines, combined, on a single base frame, a short-boom shovel for fast digging, and a belt conveyor 105 ft. long to dispose of the spoil. Various changes were made in it, but it wore out parts at an alarming rate and finally the idea was abandoned as a "theoretical success but a practical failure."

Close-up of Machine

Possibly a modification of this machine with the conveyor placed on a separate truck and supported by a tall tower may be able to give the shovel a range it does not now have, both as to depth and width of excavation, thus enabling it to proceed without risk of shutting itself in. In that case the shovel need have only capacity and not excessive reach, the material to be moved being tumbled down to it by explosives.

Combination Shovel and Conveyor Was Rebuilt

The Consumers Coal Co., instead of letting out its stripping, then a common practice but since that time less usual, decided to do its own work. Thereupon it rebuilt the Prutsman shovel.

whole machine. Heavy repair bills, especially, the frequent purchase of new conveyor belts, was a third disadvantage. In two years, Mr. Prutsman had made no gain from his contract, so he stopped work.

Backed by men calling themselves "The Coal Production Co.," Mr. Prutsman tackled the contract a second time, but in a few months the operations stopped again for want of funds.

The Consumers Coal Co. now decided to do its own stripping. The first move was to rebuild the shovel completely, the notable change being the substitution of steel construction for wood. The chances for fairly successful work were thus greatly enhanced. However, in spite of this reconstruction and its careful management, the company quit business in 1913 without having made any profit. The machine was abandoned as a theoretical success, but a practical failure.

Other men than Mr. Prutsman and Mr. Turner have spent their time and money designing and experimenting with such stripping machines. Morton E. Pugh, who spent a fortune and a lifetime with conveying belt strippers, took out his first patents on a machine that moved and dug sideways, the conveyor dumping behind. Later patents show that he separated the excavator and the conveyor into two independent machines, a steam shovel being substituted for his own excavator, and a crusher being added to the conveyor for sizing the waste before dropping it on the belt. The two machines operated on parallel tracks. Mr. Pugh also had planned to use a revolving steam shovel so that the conveyor could be on the same track just behind the shovel, and thus save the work of double tracking. Several attempts at operation were made in Iowa, but without success.

Meanwhile, stripping in Missionfield had not been idle, for there were people who still believed that the Butlers' big dragline would do the work in spite of all the failures made. In 1909, the Missionfield Coal Co. was organized with W. G. Hartshorn as president. It leased the stripping machine and other equipment from the Consolidated Coal Co., on a royalty basis. After two months of operation, the new company bought the property and machine. Easy stripping and the absence of floods and labor trouble enabled these men to make a good profit with the dragline for about sixteen months,

then repair bills began to overbalance the gains; the boilers gave out completely, and rather than replace them and risk future failure with the whole machine, the company abandoned the dragline.

These men, like Turner and Prutsman, saw that the principle of dragline stripping was wrong, because the machine would not operate on the soft bank. They also saw the faults in Prutsman's combined shovel and conveyor. The ultimate stripper, in their minds, had to combine the dumping range and digging power of the conveyor steam shovel with the ability to dig and dump in any direction. The propelling gear used by Butler Bros. was another desirable feature.

A long-boomed, self-propelled, steam shovel which could revolve in as complete a circle as Donovan's dragline, should solve the problem. All of the stripping machines up to this time were unable to stand the hard work and required constant repairs until they wore out, which did not take long. Therefore, the required stripper must necessarily be a giant in strength as well as size.

Several steam-shovel manufacturers were making small steam shovels and locomotive cranes which possessed the revolving feature, but none of the builders was willing to undertake the construction of a large revolving shovel, as they firmly believed it to be impossible.

In 1910 the Vulcan Co. constructed two revolving shovels for stripping purposes, having 1½-yd. dippers and about 50-ft. booms. Patrick Durkee and Joseph Stephenson each purchased one of these machines, putting them at work near Pittsburg, Kan. These revolving strippers were badly proportioned in the swinging parts, which caused constant breakdowns. Various men besides the original owners, have tried operating these machines, and are still attempting it today, but without making any money.

Next, the Browning Co. of Cleveland, Ohio, built a locomotive crane modified into a revolving steam shovel with 2-yd. dipper and 50-ft. boom. This stripper started work in Missionfield in the Fall of 1910, and in about six months, the factory received the "remains." The too-lightly constructed machine had torn itself to pieces, but here was a start in the right direction.

Another View of Preceding Machine as Rebuilt

The clumsy wooden construction which marked the first machine and which had been characteristic of all the earlier stripping machines, was replaced by a lighter, stronger steel construction but even this could not stand the gaff. For one thing the machine could not revolve and, for another, the four-point suspension made no provision for keeping the frame level.

The First "250"

The first revolving steam shovel in strip mining. This illustration from a photograph, taken in 1911 when the shovel was proving itself, shows the best practice of that year. The coal was drilled by hand. Where it was hard the coal was drilled as in the foreground, where it was soft rotary hand drills were used as in the centerground. "Pop" shots loosened the coal, which was loaded into mine cars by hand.

Two years of persuasion finally moved the Marion Steam Shovel Co. of Marion, Ohio, to begin the construction of a revolving shovel according to the dimensions and ideas of Grant Holmes and W. G. Hartshorn of Danville. One of their ideas was the hydraulic compensating trucks by which this immense shovel could keep a level frame on irregular tracks. This corrected one of the greatest faults of all previous machines—the twisting and breaking of the frame. The 3½-yd. dipper, 40-ft. handle, 65-ft. boom and 150 ton weight made this machine the largest in the world at that time.

In the spring of 1911, the big shovel, known as Model 250 began work in Missionfield. Old "Missionfielders" having seen the failure of so many machines, knowingly timed the downfall of this latest stripper. But this time they erred. The shovel saw years of service under conditions that had ruined its predecessors.

This first successful stripping machine had not been at work long before the news spread world-wide. Men

from Kansas, Indiana, in fact from wherever there was coal to strip, came to investigate.

The Bucyrus Steam Shovel Co., of South Milwaukee, Wis., was also aroused to action, and, following a visit of its engineers to Missionfield, built its first big, revolving shovel in 1912. Later it developed a complete line of successful stripping and mining machines. To keep the base level on these shovels, one of the axles was pivoted to the middle of the frame, giving three-point suspension when moving over irregular tracks. When the machine was at work, jacks near the ends of the axle kept the base righted.

Thus the heavy, revolving steam shovel made its entry into coal stripping and won the place it has held ever since. The development of light coal-loading shovels and various other types of equipment in recent years has brought stripping up to the point it now has attained. But the end is not yet. Stripping of coal is an art that still is advancing.

British Rules for Locating Magazines

Explosive stores in Great Britain are of four kinds, or, as the British law somewhat unfortunately terms them, "divisions." In magazines classed in division A, 300 lb. of gunpowder may be stored or half that quantity of other explosives, or, if both gunpowder and other explosives are kept, ½ lb. of other explosive is regarded as the equivalent of a pound of powder. With the same rule as to the equivalence of powder to the other explosives, Divisions B, C and D include storages containing 1,000, 2,000 and 4,000 lb. of gunpowder respectively.

The store must be licensed by the local authority in the name of the occupier, either for powder or mixed explosives. This license must be renewed annually. The magazine must not be situated below ground in any mine or quarry or in any tunnel or other underground place in which any work is being performed or any persons employed or in any place communicating with such mine quarry, tunnel or underground place.

The stores must be kept certain distances from houses and other buildings which for purposes of legislation are divided into two classes. Class 1 and 2 both include dwelling houses, shops, rooms or workshops of any kind, mineral or private railways whether or not worked by steam, furnaces or kilns, fires for boilers, machine or manufacturing purposes, magazines for explosives,

stores for explosives and what are known as registered premises. But though the buildings specified are the same in both classes, Class 1 refers solely to such buildings as are in the occupation of the licensee or to those buildings the occupier of which has waived his rights in writing whereas Class 2 refers to the same class of buildings where not occupied either by the licensee or by a person who has surrendered his rights to the more generous protection.

In Class 1 other objects are grouped. The magazine must be kept at a distance from these objects, equal to that prescribed for those already enumerated. They are: highways, public footpaths or promenades, open places of resort of persons carrying on any trade or business, canal or navigable work, dock, river-wall or sea-wall, pier or reservoir. Class 2 includes in addition to those enumerated factories, public roadways, churches or chapels, universities or schools, hospitals or public institutions, town halls or courts of justice, theaters or covered markets, buildings where people are accustomed to assemble and government buildings.

Distance Magazines Must Be Kept From Buildings

Magazine	Distance from Class 1	Distance from Class 2
	Buildings in Feet	Buildings in Feet
A	75	150
B	150	300
C	225	450
D	300	600

What to Avoid When Storing Soft Coal

Don't Pile Coal of Different Sizes, Ages or Localities Together — Keep Away Water and Wood — Once Well Warmed Coal Is Almost Sure to Break Into a Blaze

By A. J. HOSKIN

Acting Head, Department of Mining Engineering,
University of Illinois, Urbana, Ill.

Scene of University of Illinois Coal Storage Pile

THE University of Illinois purchases its fuel supply under specifications and usually maintains in storage a large reserve for emergencies. Following the long coal-miners' strike (1922), it became necessary to replenish this stock which was then completely exhausted. At that time, advantage was taken of the situation by the late Prof. H. H. Stoek, head of the mining department, who undertook a systematic investigation of the phenomena of the heating and firing of stored coal, a subject in which he had long been interested. Prof. Stoek assigned the problem to Otis G. Stewart, a graduate research scholar, who worked under his supervision up to the time of the professor's sudden death, March 1, 1923, after which it fell to me to direct Mr. Stewart's work.

The results of this investigation, which have never been published, are embodied in a report prepared by Mr. Stewart in fulfilling the requirements for scholastic credits. The report consists largely of tabulated data which are of no special interest, except in respect to the deductions they warrant.

However, a discussion of the phenomena observed, together with a few of the conclusions reached in the course of this research may prove interesting to any who find it necessary to store coal. Though no actual discoveries were made relative to the spontaneous firing of stored coal, some theories were confirmed and opportunities were afforded for the observation of firing phenomena.

SEVERAL STORAGE CONDITIONS OBSERVED

All the coal investigated had been mined in various Illinois districts. As it was to be burned in automatically stoked furnaces, each shipment as received, if not already of a grade that would pass a 2-in. screen, was crushed to this fineness. During the building of one pile, however, the crusher broke down and run-of-mine coal of all sizes up to 6-in. lump was stocked as received.

The coal was hauled in auto trucks from the powerhouse to the storage lot, a distance of two or three blocks. Each truck arriving at the lot backed up and dumped its load as close as possible against the pile, and laborers with shovels threw the coal up the bank, which was maintained at a height of about 9 or 10 ft. Some of the coal was piled by a portable bucket elevator, but the results were about the same as in hand shoveling.

Several carloads of coal would thus be stored at one time and work would then cease awaiting the receipt

of more coal. The relays between shipments allowed the sloping bank of the storage pile to weather somewhat between storage periods, and this weathering accounts for some of the subsequent phenomena. The intervals varied at times, reaching a maximum of a month. Construction of the mine coal piles studied continued until the middle of November.

The manner of piling the coal was favorable to its gravity classification, the coarser pieces accumulating close to the ground. No attempt was made to spread the coal in a series of relatively thin strata. The ground which had been used previously for the same sort of storage, was of a clayey nature and muddy at rainy times.

No effort was made to prepare the ground for the storage. The coal was handled by contractors whose only object was to form the piles. Deep waterfilled ruts were often covered by the coal, and remnants of former piles, together with leaves and twigs from neighboring trees, were scattered about promiscuously. On two sides of the large area were common board fences against which the coal was stocked. The headpiece gives an idea of the average condition of the storage floor, and shows how the coal tended to classify according to size when being piled.

IRON PIPES USED FOR OBSERVATION

It was first planned to use potentiometer pyrometers or some sort of thermocouples that would automatically record variations in temperature. The expense involved, however, proved prohibitive, and instead, 10-ft. lengths of ordinary $\frac{3}{4}$ -in. iron pipe were prepared for use as thermometer wells. The lower end of each pipe was drawn to a point, and the top fitted with a screw-cap for use in driving. These pipes were sunk into the coal piles at nearly equal intervals of about 20 ft.; but, owing to the irregular outlines of most of the piles, this distance was often varied.

Each forenoon Mr. Stewart went over these piles, taking observations with a number of accurate 10-in. thermometers whose range was from -10 to $+212$ deg. F. Each thermometer, being attached to a cord wound on a spool, was lowered in turn into a pipe to a depth of 5 ft. and left suspended. After making a complete round of the pipes in one pile and returning to the first pipe the observer would read the temperature and then lower the thermometer to the bottom of the pipe. Returning from his second round Mr. Stewart obtained the bottom readings and removed each thermometer before proceeding to another pile. Some-

times he would hang two thermometers simultaneously in a single well at the specified depths of 5 ft. and 10 ft. respectively. Occasionally, when unusual heating conditions were indicated, he has taken readings at one-foot intervals; but there appeared such uniform gradations between the readings at the 5-ft. intervals that he eventually dispensed with other readings.

When the work was well under way, the Federal Engineering Development Co. kindly donated twenty of its sentinel-type indicators, one three-dial and two single-dial sounding instruments. These instruments

Fig. 1—Pile of Coal Showing Size Segregation

As the coal is piled the fine material stays near the top of the pile, and the coarser material rolls down on the pile toward or to the bottom. If another pile is built on this the fine coal on the top of this pile is in contact with the coarse coal on the bottom of the other and the variation in size and in the age of the coal may cause a fire even if the coals in the two piles come from the same bed in the same mine.

carry the general name of "protectometers." They were promptly put into service and served to check the results obtained by the thermometers. They proved wholly dependable as sentinels over coal piles during long storage; but they were found less convenient for the research work than the simple pipe-and-thermometer units previously employed. The protectometers were more cumbersome than the light pipes. Throughout the entire investigation ample time was afforded each thermometer to register accurately. In Table I is shown the thermometer readings in two holes compared with those of contiguous protectometers.

WHERE OLD AND NEW COALS MIX, FIRE OCCURS

One pile was started with old, dried screenings from bins in the power house, and against this was stocked fresh screenings. After the completion of the pile the difference between the two halves was distinctly noticeable, the new coal being blacker and more brilliant, the appearance of the older coal being dull and dirty. Twelve days after storing, heating began to affect the thermometers along the plane of contact between these different coals. The following day the pile smoked vigorously, showing that such a contact between fresh and weathered lots of coal presents a condition favorable to spontaneous combustion.

The heating and subsequent fire spread rapidly till it reached the fence against which the pile was built. The fence quickly took fire and ignited the adjacent coal along its course, the large cracks between boards affording excellent drafts of air. Workmen tore down

Table I—Thermometer and Protectometer Readings, Contiguous Holes

Depth Feet	Degrees Fahrenheit			
	Pipe 608		Pipe 609	
	Thermometer	Protectometer Dial	Thermometer	Protectometer Dial

8	181	179	178	178
9	193	183	163	168

the fence and removed all coal showing any evidence of fire.

However, heating soon began further along the contact plane and increased so rapidly that the entire pile would have been ruined had it not been expeditiously moved to the power plant and immediately utilized. Temperatures rose from 78 deg. F. to 356 deg. F. during these observations. The portable elevator used in removing the fired coal is shown at work in Fig. 2 where it is loading a truck for transportation to the power-plant.

DISSIMILAR COALS FIRE AT CONTACT SURFACE

It was intended that a certain pile should consist exclusively of screenings from a single mine; but, after about 200 tons of this coal was stocked, receipts ceased for a time, and the pile was finished with coal from a mine in a different field. It chanced that the placing of the last few truckloads of the first kind of coal left a little level bench about 4 ft. above the ground. When the new coal was thrown upon the pile, there was a segregation of the coarser fragments on this bench the surface of which was naturally composed of the finest fragments of the first coal. This established a plane of contact between not only unlike coals but also unlike sizes. The second lot of coal contained much more pyrite than the first. This condition had not been previously noted but it was easily disclosed subsequently. Heating increased at the rate of from 4 to 5 deg. daily, and a lively combustion ensued.

When the fiery masses were subsequently excavated, coke was found mixed with half-burned coal, red ashes and a yellow, viscous substance that proved to be sulphur probably reduced from the pyrite. Iron oxide from the same pyrite was present as a fine, red dust. The conflicting reactions that occurred in this pile provide imagery for the chemist.

Before the fiery masses were removed their heat had radiated until both kinds of coal reached a temperature of 180 deg. F. This was not considered a critical or ignition temperature and yet, when the pile was opened, the spots at this temperature quickly caught fire. Here is a phenomenon deserving scientific study.

One pile was formed exclusively of coal from a single mine. However, the first few hundred tons of this coal consisted of screenings, the rest being the run-of-mine coal previously mentioned as being stocked because of a broken crusher. The plane of contact of the two sizes proved to be occupied by the coarser lumps, many of them 6 in. in diameter.

The temperature of the coal, as placed, averaged 80 deg. F., but rose rapidly, and various wells near the contact showed temperatures ranging from 125 to 150 deg. F. These temperatures were not, at that time,

Fig. 2—Portable Elevator Loading Fired Coal

When the coal fired it was loaded out and carried away to the boiler plant. Fire first started where well-weathered screenings, already dull with age, from the bins in the power house, were stocked with fresh screenings. Such coals if possible should never be stocked together.

regarded seriously, but excavation being made into the heated zone for inspection, energetic combustion started instantly.

A strip about 20 ft. wide extending through the pile along this plane of contact, was then removed and it was thought the rest of the pile was safe. Nevertheless, one of the sections of the pile burst into flames a few days later. Investigation showed that the spontaneous heating had occurred at a limited contact plane between a stratum of fine coal and the overlying stratum of coarser coal.

WATER IN RUTS APPARENTLY STARTS A FIRE

A certain pile was formed on ground badly cut up with ruts made by the heavy coal trucks in wet weather. These ruts and other depressions in the floor were filled with rainwater. This pile heated early but the temperature failed to exceed 142 deg. F. A white cloud of vapor was often visible over the pile. When a cool thermometer was inserted in a well it promptly became clouded with moisture.

The pile was assumed to be safe against fire, and yet when the coal was subsequently hauled away there were numerous pockets showing the products of complete combustion. The water appears to have induced a quick heating of the bottom coal; but the vapor that permeated the mass must also have deterred the combustion to a considerable degree.

WOOD FENCE APPEARS TO HAVE FIRED PILE

Fire was discovered in one pile where it came into contact with a board fence. The thermometer nearest to this fire read only 106 deg. F. It is believed that spontaneous heating occurred because of the coal actually touching the wood. The crevices between the fence-boards permitted just the requisite supply of oxygen without sufficiently removing the heat by circulation. By tearing down the fence and flooding the coal with water from a fire hose, the bulk of this pile was saved. Similar phenomena were observed in another pile to which corrective measures were successfully applied.

A few piles remained comparatively low in temperature throughout. In one pile the temperature rose only along a limited horizontal stratum that was unintentionally produced about 4 ft. from the ground during the stocking of the coal.

Heating always occurred in the lower half of a pile, except in the instance of the fence fire mentioned. The reduced and molten sulphur frequently found in burned pockets often matted lumps of coal together. Removal of fiery coal alone did not prove adequate to prevent further combustion. The relief was but temporary. Heat from the fire usually permeated the pile, and it may be that combustible gas also from the fire was entrapped in the coal pile ready to aid in re-establishing combustion.

The heat of any fiery spot was strongly noticeable for about 5 ft. in every direction. Heat from an interior fire travels further along strata than in a direction transverse to them.

If coal is stored in the open, the piles should be relatively shallow because firing occurs in the lower zones, and because with high piling large quantities of coal must be handled to get at a fire. Contacts of coal with wooden structures or other inflammable substances should be avoided.

Keep different kinds and different sizes of coal separate. Keep old and fresh lots of coal apart. Sort out or otherwise remove as much pyrite as possible.

Use of Rock Dust More Dependable and Less Costly Than Sprinkling

EMPLOYMENT of rock dust in coal mines to prevent coal-dust explosions should not add to the cost of coal, according to George S. Rice, Chief Mining Engineer of the Bureau of Mines. In England, where some of the mines have been using rock dust for this purpose for more than ten years, and where its use in dry mines has been required by law since 1920, the direct cost is not over 1c. per ton and in many cases not more than half that, Mr. Rice points out. However, in the United States the costs probably will be higher on account of the higher wages in this country.

This is not really an added cost as far as the general public is concerned, even though the whole cost of mining is finally paid by the consumer of the coal. Two coal-mine explosions which have cost about a million dollars each in workmen's compensation, property damage and other costs have occurred in the United States since the first of the year. Averaging the cost of these two explosions over the approximately 500,000,000 tons of bituminous coal that will be produced this year represents an added cost of approximately 0.5c. per ton that in the last analysis must be paid by the consuming public. In other words, a sum of money equivalent to the damage done by the two mine explosions (which the use of rock dust undoubtedly would have prevented) probably would have sufficed to pay for the rock dusting of all the bituminous coal mines of the United States.

Many bituminous coal-mining companies in this country, in order to keep down the coal dust, are sprinkling their mines with water at a cost several times that of rock dusting. Sprinkling is not as dependable as rock dusting, for the water continually evaporates, and if sprinkling is neglected for a short time an explosion may result. How great is the difficulty of effectually wetting coal dust is evidenced by the fact that coal dust may float on the top of water in sufficient quantity to cause an explosion even in a mine that is so wet as to make work in it uncomfortable.

How to Keep Mining Equipment in Satisfactory Operating Condition at All Times

Electrical Apparatus Should be Supplied With Rated Voltage—Repair Worn Parts by Welding and Machining—Pumps and Fans Must Not Be Required to Deliver More Than Their Normal Capacity

BY J. F. MACWILLIAMS

Electrical Engineer, Pennsylvania Coal and Coke Corporation
Cresson, Pa.

ALL electrical apparatus is designed either to generate a particular voltage or to operate when supplied with a certain quite definite electric pressure. It is, therefore, important that generating equipment deliver its rated voltage and all other apparatus receive at its terminals the pressure for which it is designed.

Burnouts, breakdowns and other failures of electrical equipment are generally the result of the low voltage it received. Excessive pressure will cause the insulation to fail; the liability of such a breakdown depending upon how great the over-voltage may be. However, too high an operating voltage is rare because of the nature of power supply systems. Consequently, electrical men and others responsible for the successful operation and maintenance of electrical apparatus need to guard mostly against low voltage.

Nearly all motors are designed with ventilation ducts. Should these passageways become only partly obstructed with oil, dust or dirt the circulation of air is reduced and the temperature of the motor is abnormally increased at all loads. If the dirt is composed of current-carrying material there is great danger of short-circuits and grounds. For these reasons electrical equipment should be cleaned at frequent intervals.

KEEPING ROTATING PARTS IN POSITION

The air gap between the revolving and stationary elements of all machines should be inspected frequently. Normal wear of bearings gradually decreases the clearance at the lower part of an armature or rotor. When the air gap is not uniform the unbalanced magnetic attraction causes the shaft and bearings to wear much more rapidly than when the revolving element is in a central position.

Commutators should be kept smooth and clean as dirt and roughness will cause them to deteriorate rapidly.

Motor and generator fields should be kept in good condition. A weak motor field increases the normal operating speed and usually strains the armature windings. Unbalanced fields cause cross currents to flow in the armature and result in excessive heat.

When a motor or generator is designed certain characteristics determine the grade and type of brush to be used. After the motor is completed the manufacturer makes a thorough test of the motor and much time and money is spent to ascertain whether the brush previously selected is satisfactory. For these reasons it is always advisable not to change the grade of brush supplied by the manufacturer without first making a careful investigation.

Particular attention should be given to the proper

lubrication of electrical apparatus. Too little oil on motor bearings will cause excessive heat and wear, whereas too large a quantity will overflow and be sucked into the windings where it quickly rots the insulation.

Storage batteries should always be properly charged. The cells should be frequently examined to determine the level of the electrolyte in the jars. A proper charging current is essential to long life and efficient service. Each week the battery should be given an equalizing charge so as to be brought back into step with the ampere-hour meter.

Locomotives should never be run with broken frames or bumpers, as the bearings, gears, axles, etc., thereby are subjected to excessive wear and the motorman is exposed to great danger. Worn bearings, housings, and axles should be built up by welding and then machined so as to fit properly. If there is much lost motion in these parts, the power of the motors is partly absorbed in pushing the gear and pinion apart and clashing the teeth, instead of being used in useful work.

OPERATE EQUIPMENT PROPERLY

Motor suspension springs should be maintained in good condition; they absorb the initial shock that the motor gets when the power is applied. If these springs do not take the shock the shafts and gears are almost sure to be broken.

Starting locomotive motors in parallel is an all too prevalent practice around coal mines. When the motors are started in this manner the locomotive must accelerate twice as fast as it should. Smooth operation and greater starting torque can only be obtained by starting the motors in series and later changing them over into parallel.

No locomotive should be allowed to run on any mine track when the wheels have developed a false flange more than $\frac{1}{4}$ in. high. The delays and high maintenance costs of locomotives and track are excessive when the wheels have high false flanges. Turned-down locomotive wheels should be paired so that their diameters will not differ more than $\frac{1}{8}$ in.

Soldered cable and wire joints are always to be preferred, soldered feeder ears and connectors are better than mechanical connectors. The size of current-carrying conductors should never be less than that specified by the National Board of Underwriters. It must be remembered that these recommendations are based upon safe heating capacity and consequently larger conductors must frequently be used where the lines are long. Otherwise the loss of voltage in the small conductor may be quite large.

Electric generators are designed to deliver a certain current at a definite pressure. This is also true of fans and pumps. We would not expect to drive a

NOTE—Paper delivered before Mining Institute at Barnesboro, Pa., May 24.

Storeroom and Repair Shop

In the mine machine shop large savings can be effected by prompt repair service. Partly worn equipment can be easily welded and placed in the stock bins instead of being lost in the mines or put in the scrap pile.

generator built for 250 volts at a speed necessary to develop 500 volts, so why should we expect a fan or pump to operate satisfactorily at greater capacity than that for which it was designed? An electric generator if short-circuited may burn up; likewise, a pump or fan is subjected to strains if the head is reduced or the flow is short-circuited.

Usually plunger pumps are purchased because they can be operated at high efficiency, therefore special care should be taken so as not to defeat the purpose of the management. It is possible by not removing old packing or by pulling up new packing too tightly to

decrease the efficiency of a plunger pump 30 per cent. Loose packing and a little leakage of water at the glands is much better than tight packing.

Some types of centrifugal pumps are designed so that the bearings are water-cooled. Pump operators, especially those who have been accustomed to maintaining plunger pumps, should be careful not to pack the glands so tightly as to score the rotor shaft or shut off the cooling water. Water-seal rings in centrifugal pumps should never be removed or placed in a position on the shaft where the sealing water cannot properly enter them.

Peabody Picture Film Shows Mine Explosion

“WHEN a Man’s a Miner: a Story of Safety in the Coal Mines” is the title of the latest addition to the series of industrial motion picture films prepared by the Bureau of Mines in memory of Francis S. Peabody, and at expense of his son, Stuyvesant Peabody.

In this film, which is four reels long, the principle of “Safety First” is woven into the story of “Lucky” Burns, a carefree young coal miner who is inclined to laugh at danger and to take big chances in order to increase his daily output of coal. “Lucky,” however, learns the lesson of “Safety First,” as shown in a realistic scene where his neglect to pull down a block of loose coal results in his leg being crushed. His life is saved by a “buddy” whose knowledge of first aid enables him to apply promptly the proper emergency measures. “Lucky,” after his accident, concludes to take the first aid and mine rescue training offered by the United States Bureau of Mines, a knowledge which is of immense practical aid later in the story.

Following the arrival of the Bureau of Mines rescue car in Tiptonville, the typical midwestern coal mining town in which the story is laid, the gathering of several hundred coal miners at the mine mouth for their day’s labor is shown. The miners obtain their “life checks,” descend the shaft, and proceed in long trains of mine cars through the shadowy underground depths to their daily work. As “Lucky” and his “buddy” are engaged in loading coal the sound of a mine explosion is heard. They rush toward an entry, only to sense that deadly mine gases lie in that direction. “Lucky,” utilizing his new knowledge, retreats to a safer part of the mine,

gathers about him a number of his comrades, and instructs them in the method of building a barricade to protect themselves against the deadly afterdamp.

Meantime, in a series of vivid pictures, the power-plant whistle gives the disaster signal; the frenzied women and children of the town rush to the mine entrance; and the rescue men trained by the Bureau of Mines, wearing oxygen breathing apparatus, hasten to the aid of the imperiled miners.

Behind his hastily improvised barricade, hundreds of feet below the surface, “Lucky” Burns instructs his “buddies” how to conserve their limited supply of oxygen. He puts out crudely written signs to guide the rescuing party, and details men to rap on the rib as a signal to the rescuers.

Vivid glimpses of the rescue crew making their way through the dark mine passages are given, and finally the rescue of the entire party, made possible by the conversion of “Lucky” Burns to “Safety First” principles is depicted. “Lucky” has his reward in winning the hand of pretty Mary Kincaid, the girl of his choice. He is awarded the Joseph A. Holmes safety medal for heroism in time of mine disaster and is appointed mine safety inspector for the Tiptonville district.

The film will be available, after June 15, for exhibition purposes by educational, civic, commercial and similar institutions and may be obtained from the Bureau of Mines, Pittsburgh, Pa.

IT’S FUNNY ABOUT COAL FIRES. The Astoria Light, Heat & Power Co., of New York, is proud because its fire has burned one hundred years. The Alden Coal Co. is proud because its fire has finally been put out.

Mechanical Loading Problems and Their Relation To Room-and-Pillar and Longwall Workings

Ayrshire Coal Co's Experiences with Cars of 3200-Lb. Capacity—
Forty-Eight Cars Loaded per Day—Wagons Placed with Less Than
One-Minute Waits—Control of Roof the Problem with Longwall

Mechanical Coal Loading in Room-and-Pillar Mine

David Ingle, president of the Ayrshire Coal Co., in the closing session, May 15, of the meeting "On Correlation of Mechanical Loading with Haulage and Mining Systems" of the American Mining Congress, gave a description of the conditions under which his machine loaders operated and detailed the results obtained. Last week on p. 811 is contained his description of the mine. In detailing the method of shooting down and loading the coal Mr. Ingle said:

All the coal is undercut before being shot. Three holes usually are drilled and in general black powder is used although experiments have been made with other kinds of explosive. Mules are used to gather the coal and to furnish cars to the loading machine. An endeavor is made to have a switch in each working place, set as near the face of the coal as possible so that the minimum time will be lost in shifting cars. The purpose is not to allow any working face to get more than 200 yards from the gathering place.

NO MORE HAND LOADING

The mine has been operating since December, 1922, and since that time not a single car has been loaded out by hand. Seven Joy (4 B. U. type) machine loaders have been used. A record has been kept of these machines. Several months ago a man with watch, pencil and note book began keeping a record of just exactly what each machine did in an eight-hour day. Twenty-five different records were made.

The results obtained in the last eight days are set forth in Table I.

Some coal hangs up refusing to fall and the loader had to be stopped while

the operative broke the coal down so that the loading machine could get at it. The coal could be shot hard enough to overcome this loss of time, but if this were done the coal would be broken up unduly.

The delay in cleaning up the corners with a hand shovel was due to the fact that the Joy machine has a wide and straight loading end and as the corners of the room are square all the coal could not be loaded by the machine. The machine is kept at right angles to the face so that only a little coal is left in the corners. This is something peculiar to this machine loader which is the smaller of the types manufactured.

Breakages do not now cause as much waste of time as they did in the first

Each loading machine is given six places, though it is really unnecessary to provide so many. As there are seven machine loaders there are 42 places, whereas with hand shoveling there would probably be 75 places, for, under the agreements, with hand shoveling three places have to be allotted for every two men. With 50 men loading by hand 75 places would be needed instead of 42. This shows how greatly the work can be concentrated. In the hand-loading mines of the Ayrshire Coal Co., the production averaged 5½ tons per day per man for a period of three months. To some that may not appear to be a large production, said Mr. Ingle, but that is what the figures showed including every man on the payroll. With the machines the output

Loading Mine Cars

The loading boom has to be placed above the top of the car so that in low places it is necessary to use a low car. This illustration proves that large material can be loaded by machine—
Courtesy, Myers Whaley Co.

months of operation. Still too much time is lost, and the new machines are expected to do better. The loading tracks are of 16-lb. steel and are laid on steel ties. They are easy to shift. Mr. Ingle said he thought the short time consumed in shifting track was quite creditable. For the time lost for lack of power there could be no excuse, for it could be avoided entirely by keeping the power lines in good condition.

UPKEEP COST 7-8c. PER TON

With these machines 48 cars each containing 3,200 lb. a total of 75 tons were loaded daily per machine. The cost of upkeep for four months has averaged between 7 and 8c. per ton. That cost includes the upkeep on the cutting machines which is, of course, only a small part of the charge. The cost for explosives is 3c. per ton. As the work is done by the day all the explosives are furnished by the company which also does all the drilling and shooting. The cost for gathering with mules does not seem to be any more than for gathering with machines in hand-loading mines, because the territory to be served is smaller.

is 7 tons per day per man or a gain of 1½ tons. It is costing 85 per cent as much to produce coal by machines as by hand loading.

Questioned by Howard N. Eavenson, the chairman, Mr. Ingle said that 43 min. were lost in shifting 48 cars from the nearest switch point to the machine. That is more than one car per minute. Mr. Ingle said that no objections were raised by the union to the introduction of the machines. The district leaders set the scale for their operation at \$12 per day, the rate paid for operating a different type of machine at a mine ten miles away.

OPERATOR AND HELPER SPLIT PAY

Since that time the sum that was paid the operator and his helper has been divided equally between them. As the helper was getting \$8 per day the new rate is \$10 for each of them. That is good pay, but said Mr. Ingle, skilled men were needed on the job. Men who operate cutting machines are making \$15 and \$20 a day on tonnage rates. If the machine loader would not be profitable at those rates it could not hope to succeed.

NOTE—Part of discussion on "Correlation of Mechanical Loading with Haulage and Mining Systems" at the Cincinnati Conference and Exposition of the American Mining Congress.

Making Cars Large and Low For Machine Loading

Mr. Eavenson in discussing Mr. Ingle's address on the operation of the Ayrshire Coal Company's mine said it was remarkable that cars could be delivered to the machine with a loss of only one minute or less. The loss of time had appeared so important to persons installing machines that they were using cars of unusual capacity in order to reduce that loss to its lowest limits.

D. J. Carroll was using a 5-ton car with loading machines at the Chicago, Wilmington and Franklin mines and one operator was introducing 7-ton cars. Mr. Hockensmith said that the problem had been to devise a car that would have the same capacity as the old cars and yet leave room for loading with a mechanical loader. That made necessary a departure from the wooden mine car. By using a composite car, part steel and part wood, the capacity was increased 10 per cent.

OUTSIDE FLARE ELIMINATED

In the last few years the Hockensmith Wheel & Mine Car Co. has devised a semi-box type in which the flare at the sides is eliminated and the wheel is partly housed. This reduces the over-all height from 3 to 6 in. and adds 25 to 50 per cent to the inside capacity. A car has been constructed in the last few years that will hold 3,200 lb. without exceeding the outside dimensions of one of an early type that carries only 1,600 lb.

A car built for the Pittsburgh seam had an increase in capacity over former designs of 25 per cent. The machine operators now need cars that will hold 5 to 7 tons. These can be provided if the seam is thick enough, the roof is good and wide roadways are possible and are provided. The cars in the Pittsburgh region are relatively short. In West Virginia they are 10 to 12 ft. long, and they work satisfactorily but they cannot be constructed of wood. A wooden car would not withstand such loading.

A car 42 in. high, 6 to 7 ft. wide and 12 ft. long has been constructed to carry 7 tons. In order to start long trips with the larger types of cars special draft gear must be provided. The semi-box type of car can be used with other cars without material change of equipment. With a change from the semi-box to the true box type of car an increase of capacity of 10 to 15 per cent can be attained.

STEEL CAR LIGHTER THAN WOOD

A car only 24 to 30 in. above the rail can be built to carry 3 to 5 tons, but such cars can be used only with rotary dumps. The cost of a car divided by its carrying capacity will be about the same whether it is constructed of steel or of wood, for wood has greatly increased in price and will increase still more. A steel car can be built that will be lighter than a wood car of the same capacity. Some steel cars built over twelve years ago out of bessemer steel are only now being repaired. If they had been constructed of open-hearth steel they would have had a longer life by 25 per cent. The upkeep on steel

cars is not expensive so far as repairs are concerned. If they get in a wreck they can be put in a frame and be jacked back into shape. The same wreck would make it necessary to rebuild a wooden car.

It might be interesting to add that investigation has shown that the 18-in. wheel used in the Pittsburgh region is too large. It should be replaced by a 12-in. wheel. Tests the Hockensmith company has made show that the smaller wheel has the advantage because of its lighter weight. The Department of Mines will have a definite pronouncement to make on this in sixty days.

How Does Roof Break Ahead Of Face in Longwall

In the time devoted to the subject of the use of loading machines in longwall working, R. Dawson Hall, engineering editor of *Coal Age*, discussed the nature of the roof break beyond the longwall face prefacing his remarks, however, with the advantages inherent in longwall provided conveyors are not used and the roof tends to break in a manner favorable to operation. He remarked that he had always been an advocate of longwall mining in connection with loading machines.

Where Does It Break

At A B or C D B? If it breaks along the former line it will be impossible to hold the roof when the point A is reached unless the mined area has been closely back filled.

It has the advantage that the face can be cut and loaded continuously, the coal being fed by the machine loader into a trip of cars steadily moved in front of the face which is being loaded. Consequently less time is lost in placing each car in front of the loading machine. However, the progress of the conveyor has shaken that faith. Nevertheless conveyors are expensive and many will desire to use cars instead and consequently will continue to favor the longwall face.

Attempts might be made where something of the nature of a longwall face is being worked to deliver the coal to a trip of cars which pass at right angles to the longwall face on a roadway leading to one of the main roadways of the mine. But as the rear end of the trip when the front car is presented to the conveyor is well back in the goaf, cribs are needed along the roadway and these support the roof for a while but the working thus inadequately supported is always in danger of a sudden and dangerous squeeze or fall which may close the working face and injure the machinery.

Great Britain has a number of longwall faces but we must be cautious in accepting the results obtained in that country as a guide, because in Great Britain it is customary to fill the excavated area, the coal being, in most cases, sufficiently thin to make that practice actually economical for some place must be found for the stowage of waste.

In the early days when subsidence was first being discussed, said Mr. Hall, he was already an advocate of the conclusion that the roof broke back over the solid coal and the roof thus broken could not come down till the coal was removed. The principle which led to that conclusion was derived from the action of a stick held over an edge and pressed down. The stick broke over the support instead of at the ends. George S. Rice has been an advocate of breakage at the extreme edge of the pillar declaring that the roof did not fracture over the coal, at least in room-and-pillar workings.

BREAKAGE DUE TO "DRAW"

That fractures occur over the coal has been abundantly proved in Great Britain. This breakage has been described appropriately as due to "draw"—that is, to a tension in the measures above the coal. But in the United Kingdom the practice has been to deny that this fracture is vertical or even nearly vertical. It is argued correctly that the main roof is partly in tension and partly in compression, an area lying between the two which is neither in tension nor compression but at zero stress. This is known as the neutral area, it corresponds to the neutral axis in beams.

This area lies about one-ninth of the distance between the surface of the ground or upper surface of the rock and the top of the coal or drawslate. The compressed rocks compose the lower ninth and the stretched rocks compose the upper eight-ninths. So far the argument is indisputable. The British assert that the break near the coal slopes out into the gob until it reaches the neutral area and that from that point it slopes back away from the gob and over the coal, its extremity reaching the point of draw. Actually, of course, this break starts from the surface and works down to the neutral axis. Thus the break is not straight nor vertical but an angle break, one break extending from over the coal into the gob and the other extending from over the gob back to or toward the coal.

There is no question but that the observation that the rock above the coal breaks toward the gob is abundantly proved in practice, but the assumption that it connects with the break that comes down from the point of draw is not susceptible of proof. Moreover the lower break, that toward the gob, may be in the drawslate only and not in the roof proper. It is difficult to determine how far above the coal the drawslate extends and how much of the roof may be regarded as a monolith. The lower break may not extend any further than to the true roof. So far every assumption as to the slope of the fracture from the point of draw is a mere surmise. No one has been able to follow it.

News Of the Industry

Summer Storage by Railroads Would Level Coal Production

Coal Exports Tell International Railway Fuel Association That 20,000,000 Tons Each Summer Would Turn the Trick—Many Methods Discussed to "Save that Pound" During 1924

If the railroads would store 20,000,000 tons of coal during every summer, as they did in 1923, it would go far toward solving the coal problem of the nation. The country would follow their lead and they would benefit largely. This doctrine was driven home to 500 railroaders in Chicago last week at the seventeenth annual convention of the International Railway Fuel Association. F. G. Tryon, of the U. S. Geological Survey, laid the groundwork in an illustrated talk pointing out the painful fluctuation of coal production and the steadying effect the 1923 railroad-storage program had on it. Then along came Eugene McAuliffe, president of the Union Pacific Coal Co.; F. R. Wadleigh, of the Tuttle Coal Co., and C. F. Richardson, head of the West Kentucky Coal Co., hammering the idea deeper. Even the association's own committee on storage, surveying the attention the subject had been getting all year in the country, said that "it is the duty of each consumer to consider his responsibility in the matter of storage and see what he can do for himself."

"Save that pound of coal!" was the slogan of the association—an organization made up mainly of executives, operating men and fuel supervisors keen to help the lines of the world to get more out of what they burn. The slogan wasn't officially adopted, but R. H. Aishton, president of the American Railway Association, voiced it during the first session so punchfully that it just naturally was sounded all down the line of speakers from both railroads and the coal industry.

"Save Pound" in Various Ways

"That pound" was saved—verbally—by a variety of suggested methods, both direct and indirect. The burial of the old ax of enmity between railroad purchasing agents and coal men would help save it, Mr. Wadleigh intimated. It was saved by better fuel inspection and by better inspection work by the railroads at mines, proposed by Malcolm Macfarlane, chief fuel supervisor for the New York Central Lines. It was saved fifty times over by many railroaders proposing economies great and small. It can be done because "that pound" per 1,000 gross ton miles was saved nearly three-fold last year, according to Mr. Aishton, reducing the

average consumption for that haulage unit 2.8 lb., or down to 160.1 lb. To do that again would save the railroads \$3,165,000, he declared.

The four-day meeting was a wide-awake convention of the type this as-

©Harris & Ewing

F. G. Tryon

Parliamentary question by Geological Survey attaché, on summer coal storage by railroads, arouses deep interest at International Railway Fuel Association convention.

sociation has been holding every year since 1908, when Eugene McAuliffe and 35 other railroad men who understood coal started the organization. The first few years were not noteworthy for the approval they won from the executives of the world's railroads. But the staggering fuel waste by railroads was a subject that gave the engineers, firemen, roundhouse foremen, road foremen of engines and fuel men composing the association their chance to propose and demonstrate real savings to their companies. The resultant change in the attitude of the executives toward the association was exemplified by the presence and participation at this year's convention of a good many such executives.

The doctrine of great coal storage by railroads was preached strongly. Mr. Tryon brought it up "merely as a parliamentary question" but nevertheless

forcefully in his address, which will appear later in *Coal Age*. He incidentally raised one of the few voices to be heard in this country in praise of the U. S. Coal Commission, when he paid tribute to the value of the great mass of data on coal and coal mining which the commission collected. He defended the commission in a few words for not producing a panacea for all the ills of coal. The commission showed good judgment by not trying to produce any such thing, he said.

His "parliamentary question" was: "Why should not the railroads of this country store 20,000,000 tons of coal every summer?" He showed with charts how the coal production of the nation fluctuates wildly and disastrously to everybody concerned, including the railroads, and pointed out how the coal production curve had been flattened during 1923 by the admirable program of storage in which the country indulged. Railroads stored 19,800,000 tons early in 1922 against the strike and 19,000,000 tons during the summer of 1923, as compared with a storage of but 13,000,000 tons to meet the emergency of war. Thus he demonstrated that 20,000,000-ton storage programs are entirely possible by American railroads. The exact cost should be studied to determine just what losses there are from fire and chemical change and what counterbalancing gains there are by getting railroad coal out of the way of revenue coal each fall and winter.

Cites Example of 1923

Coal production now is so heavy that the railways never again can handle it in bursts, as formerly, without tremendous additions to equipment. This probably never will be necessary, he said, if the whole country, led by the railroads, will store every year as it did in 1923. He urged the roads to let their reserves work down to about 5,000,000 tons each spring and build them up to 19,000,000 or 20,000,000 tons by autumn, carefully timing the movement of this deadhead coal so as not to interfere with revenue coal. This timing means more money to the railroads than many may realize. He estimated that if railroad coal moved an average of 150 miles from mine to consuming point the average cost to the road of handling that coal would be about \$1.30. Multiply this by the 150,000,000 tons of railroad coal consumed annually and the roads can easily realize that getting their own coal is enough of an item of operating cost as it stands without letting railroad coal cut down freight revenue by getting in the way of revenue coal.

When Mr. Tryon finished showing his

charts H. T. Bentley, general superintendent of motive power for the Northwestern, rose to declare it was "the best thing I ever heard," and moved that the paper be printed and distributed.

"Twenty million tons moved in and out at the right times will balance the bituminous production of this country," Mr. McAuliffe told the convention. Maintaining this balance, he said, would benefit the railroads not only financially and in steadiness of rail traffic but in public esteem too. To prove this he declared that 50 per cent of the public criticism of the railroads has been raised at the times that the lines failed to deliver coal to the people when they wanted it. The reason the railroads couldn't deliver it was because so little coal had moved in the summers that it congested in the autumns.

The discussion that day veered for a while to coal miners' wages. Mr. McAuliffe said the agony of fluctuation in the demand for coal had given miners such irregular working time that some of the best racial groups of miners in this country, notably the English, practically quit the industry. The men of all colors and degrees that remained in such great numbers had to have a wage high enough to earn them a living. For this reason some of the most ignorant among them are paid a higher rate than the average American locomotive engineer. McAuliffe himself once was an engineer.

Then came C. F. Richardson, another "hog head" of other days and now head of the West Kentucky Coal Co., telling the audience that miners' wages certainly ought to be lowered but that he believes they ought to get enough work to provide them 4½ or 5 days a week. This, he thinks, should be a part of a big program of regularizing the coal industry. Railroads should help in that process by buying regularly and at such times as would best fill in the low points of the market.

Mining Not Wilfully Wasteful

Still another coal man who used to pull an engine throttle, M. B. Morrow, operating head of the Camnor Coal Co., operating in Alberta, defended the coal operator against the charge of willful waste of coal in the process of mining. He admitted that much coal of low grade must be gobbled because of the presence of impurities in it and showed the reasons for the abandonment of pillar coal, but held that the percentage of extraction in this country still is more than 50 per cent. Recovery of the balance is too expensive to be economical.

"The antagonism that undoubtedly exists" between coal men and the railroads ought to be wiped out, according to Mr. Wadleigh, who was Federal Fuel Distributor and therefore had close contact with both industries before he left the government service last autumn. This is partly due, he thinks, to constant effort on the part of so many purchasers of railroad fuel to beat down the price and to the lack of mutual understanding between railroads and mining companies of their industrial problems. The railroad often loses in the end because of this condition.

He urged that railroads give more

attention to the importance of their coal traffic and that some sort of uniform contract for coal purchases be worked out and agreed upon by both industries. He spoke of the proposed "coal institute" which may be of such great technical and economic help to the coal industry and recommended that the International Railway Fuel Association co-operate with it when it is formed. He also urged closer study of the economic side of coal storage by the railroads so as to bring out all the phases of the storage problem.

©Harris & Ewing

F. R. Wadleigh

Former Federal Fuel Distributor, who favors coal institute and indorses proposed summer storage by railroads.

An appeal for better handling at the mines of railroad coal was made by Mr. Macfarlane. If the railroad fuel of this country contains but 10 lb. of non-combustible matter per ton, then there are 15,000 fifty-ton carloads, or 200 trainloads, of such matter hauled and handled every year adding to the cost of fuel and cluttering up channels that ought to be free for good coal.

The miner at the face is the man who should get most of this burden off the railroad, Mr. Macfarlane thinks.

He urged that in loading mine-run railroad coal at the mine the sizes be more thoroughly mixed so that when it gets into use, one engine will not receive a tank full of machine slack while the next one gets all lump.

Railroads should set up larger and more efficient forces of fuel inspectors who would study coal and know its conditions and handling all the way from mine face to coal chutes. Many improvements in the quality and preparation of railroad fuel have been made, he said, because an inspector actually studied mine and tippie conditions and made suggestions to the mine operator.

The greatest railroaders' interest of the convention was awakened by D. F. Stevens, general superintendent of the Baltimore & Ohio, who read a paper showing how division superintendents can make great fuel savings by bearing coal in mind as they handle the movement of their divisions.

The association's committee on storage reported that much study had been given the subject all last year by many

agencies and that the general result was good, but that the public must get the storage habit before storage will give the coal industry much relief. The committee gave much space to the report of W. L. Abbott's committee of the Federated American Engineering Societies, in which "a sustained policy of storage by railroads in quantities similar to the practice of the past year is indicated as of advantage to the roads and to the public." The problem of spontaneous combustion, however, needs much further study.

In a symposium on coal and oil fuel R. E. Rightmire, engineer of tests for the Consolidation Coal Co., spoke briefly of the improvement in the preparation which railroad coal has received, due partly to increased coal inspection by the roads, partly to the fact that of late coal had to be well prepared or it wouldn't sell, and partly to the fact that there are some operators who take pride in their output. Apparently the present standard of quality will be maintained so long as there are no serious disturbances affecting coal production, he said.

George W. Reed, vice-president of the Peabody Coal Co., welcoming the association to Chicago on behalf of the coal fraternity of the city, remarked that 20 per cent of the coal produced in the United States is sold through Chicago, 95 per cent of this by rail, and that therefore there is a close interest between the Chicago coal man and the railroad. Of all the Chicago-handled coal, he said, 86 per cent moves direct from producer to consumer. This is an important low-price factor probably not equalled in any other industry.

He paid tribute to the increasing attention railroads are giving to fuel economy. Last year with 50 per cent more traffic than in 1914, the railroads consumed only 3 per cent more coal. He said the country's coal operators are trying to help in this improvement of efficiency by preparing coal better every year. Today it is an actual fact that operators are shipping coal cleaner than nature made it.

In the election of officers at the final session P. E. Bast, J. W. Dodge and J. R. Evans were candidates for the presidency, nominated by a committee. Mr. Bast won by a large vote and Mr. Dodge moved that it be made unanimous. Thus Mr. Bast succeeded M. A. Daly, of the Northern Pacific. The other officers chosen were: Vice-presidents, J. R. Evans, C. & O.; J. W. Dodge, Illinois Central; E. E. Chapman, Santa Fe. New members of the executive committee are: A. W. Perley, Oregon-Washington Railroad & Navigation Co.; T. C. Hudson, Canadian National; O. J. Brown, B. & M.; W. J. Tapp, D. & R. G. W.

Berger Wants Government to Own Natural Resources

Victor Berger, Socialist, of Wisconsin, has introduced in the House of Representatives a joint resolution proposing that the government take over and operate the natural resources of the country, including coal, minerals, oil, water power, waters and forests. The resolution was referred to the House Judiciary Committee.

Varying Estimates of Coal Stocks Reveal Need of Accurate Consumption Data

Texas Retailers' Convention Urges Summer Buying

Figures Necessary for Intelligent Production and Buying—Would Prove Valuable Business Barometer—Small Outlay by Congress Required—Incomplete Statistics Responsible for Heavy Losses

By PAUL WOOTON
Washington Correspondent of *Coal Age*

Some exception has been taken to reference, in this correspondence last week, to 65,000,000 tons as the amount of coal in storage on April 1. That figure was arrived at only after due study had been given such information as throws light on the extent of storage. The fact, however, that the figure was questioned prompted an inquiry of various coal specialists as to their estimates of storage on April 1. These estimates varied from 40,000,000 tons to 75,000,000 tons. The inquiry also developed that the men who are specializing in coal recognize that one of the important elements in the present situation is the amount of storage.

While the reference to the 65,000,000-ton figure was made only incidentally in an effort to reflect opinion to the effect that consumers would be well advised to buy coal now, when it is selling below cost, and save their stock-piles against the time when transportation may be scarce and coal prices higher, this incident has emphasized the deplorable lack of figures showing current consumption of coal. Not only are such figures necessary for the intelligent production and purchase of coal but they would furnish one of the most valuable business barometers just at this time when there is such difference of opinion as to the extent industry is slackening its pace.

It would cost only \$20,000 a year for the U. S. Geological Survey and the Bureau of the Census, possessing as they do going statistical divisions handling coal exclusively, to compile a stock report quarterly.

As it is, the only way of estimating consumption is to take the figures of the railroads, the public utilities and the few large industrial establishments which prepare such statistics. There are figures showing the amount of coke burned and certain other facts which can make the estimate more accurate, but at best it is only an intelligent guess.

When it is considered that great losses could be avoided by having these figures, it is difficult to understand why there should be this loophole in our coal statistics. Since the public is the chief beneficiary, it frequently has been suggested that Congress appropriate the small amount needed. With that parsimony which characterizes the attitude of the appropriations committees toward the mining industry, this item fails to get into the supply bills.

There are some who contend that there is little use to provide consumers of coal with this information, as most of them would pay no attention to such figures. This contention is that with a few outstanding exceptions, coal is used with less intelligence than nearly any other operation entering into the

business of conducting industry. The average consumer burns storage when he finds that coal is selling for less than it was when he bought his reserve. By the time he has consumed his stock on hand and he prepares to go into the market again, he finds that coal has risen in price. Then, being low on coal, he rushes into the market along with thousands of others who have done the same thing, with the result that prices are forced to abnormal levels and the railroads are called on to handle an unnecessary peak in the coal movement.

The foregoing, however, is a minority view. The majority believe that the storage idea is well entrenched. There are current statistics to show how well the railroads, the public utilities and the large manufacturing plants have learned the lesson. Enough is known of the practice of smaller concerns to justify the belief that they too have change their policy. All consumers, however, would be able to regulate the amount of their storage more intelligently were there a positive knowledge as to the general level of stocks.

A warning comes from an important official source that in calculating the extent to which reserves of coal can be depleted consideration must be given to the possibilities of weather conditions that would interfere with transportation efficiency. For several years the winters have been open ones. The railroads have been able to operate during the period of grain movement and other heavy demands for transportation without having to combat much unfavorable weather. There always is the chance that the next winter will set in early. Not only would that interfere with the efficiency of transportation but the early advent of cold weather would accentuate the autumn peak, with resulting price increases and the possibility that many plants might be unable to obtain the supplies necessary to continue operation. That official expresses the opinion that the provident consumer buys in a buyers' market and does not put himself in the position where he must buy in a sellers' market.

Ruhr Coal Strike Settled

Indications point to the resumption of work this week by the Ruhr miners who have been on strike, refusing to accept a lengthened working day. According to an announcement May 31 the miners' union decided that work should be resumed on the terms of the award made by Dr. Syrup, special arbitrator of the Department of Labor. The award, announced May 27, grants a 5 per cent increase in wages.

The Retail Coal Dealers' Association of Texas met in nineteenth annual convention in Vernon, Texas, May 20 and 21, with a large attendance.

In compliance with a written request by Herbert Hoover, Secretary of Commerce, a campaign was ordered and will be inaugurated immediately under the direction of Secretary Goldman to induce coal consumers to purchase their winter supply of fuel during the summer months. Representatives of miners, operators, wholesalers and railway companies present pledged co-operation to the fullest extent.

J. E. Simpson, an operator in the Henryetta (Okla.) field, declared that wages and freight rates put into effect during the war period have not been reduced in the coal industry as in other lines of activity, and this makes appreciable reductions in the prices of coal impossible, he said. Operators, wholesalers and retailers are operating on the smallest margin of profit possible with safety, he said.

Senator F. R. Wood, of Trinidad, Colo., president of the Colorado-New Mexico Coal Operators' Association, urged closer co-operation among operators, wholesalers and retailers to bring about a higher standard of ethics and business practices in the industry as the best means of eliminating waste.

Elijah Coles, of Houston, president of the association, reviewed in his annual address the association's activities during the year, and related at length efforts that had been made to bring about all-year buying of coal to the end that the industry may be stabilized. Mr. Coles referred to the fact that there are about 2,000 retail coal dealers in Texas, but that so far only about one-eighth of this number had become members of the association, and suggested a campaign to increase the membership of the association.

C. R. Goldman, of Dallas, secretary of the association, reviewed the work of the association during the seven years he has been secretary. Closer co-operation among the retailers, he said, may be regarded as the outstanding accomplishment of the association.

Gomer Jones, of Muskogee, Okla., vice-president of District 21, United Mine Workers, in a brief address pledged the co-operation of the mine workers of his district in any movement looking to the improvement of conditions in the coal industry.

W. F. Sterley, of Fort Worth, general freight and passenger agent of the Fort Worth & Denver City Ry., said that only by starting the movement of coal during the summer could it be hoped to avert a car shortage during the fall and winter months when the demand for coal becomes heavy.

At the closing business session on Wednesday, Houston was selected for the convention city in 1925 and Harvey S. Trewitt, of Dallas, was elected president. Other officers elected are: W. N. Martin, of Vernon, first vice-president; D. F. Bushnell, of Waco, second vice-president; C. R. Goldman, of Dallas, secretary and treasurer.

More Connellsville Plants Return to 1917 Scale

Effective May 27, the following companies in the Connellsville coke region reduced wages to the Nov. 10, 1917, scale: Hillman Coal & Coke Co., Oliver & Snyder Steel Co., Washington Coal & Coke Co., Puritan Coke Co., Consolidated Coke Co., Reliance Coal & Coke Co. and Redstone Coal & Coke Co., the two latter being subsidiaries of the Weirton Steel Co.

All these companies continued at work without any trouble at the reduced wage scale. The Hillman Coal & Coke Co. is firing some additional ovens at the Isabella plant, at Hillcoke. The Westmoreland-Fayette Coal & Coke Co., at Cheat Haven, Pa., which had been idle for several months, has resumed operations at the 1917 scale.

The Republic Iron & Steel Co., W. J. Rainey, Inc., and the Monessen Coal & Coke Co., subsidiary of the Pittsburgh Steel Co., have not yet made any reduction.

The following are the rates paid under the Nov. 10, 1917, scale:

	Rates Before Reduction	
Pick mining and loading, room and rib work, per 100 bu.	\$2.29	\$3.24
Pick mining and loading, heading work, per 100 bu.	2.52	3.56
Loading machine mined coal, per 100 bu.	1.65	2.10
Pick miners drill their own holes and furnish their powder, while the company drills holes and furnishes powder for machine-cut places.		
Drivers, rope riders, motormen, snappers, blasters, timbermen and tracklayers (8 hrs. per day)	5.00	7.50
Helpers for same (8 hrs. per day)	4.35	6.75
Inside common labor (8 hrs. per day)	4.15	6.55
Mine mechanics and wiremen (8 hrs. per day)	5.00	7.50
Outside common labor (9 hrs. per day)	3.30	3.60 to 4.50

Eastern Coal Retailers Scan Trade Problems

Nearly a thousand retail coal dealers of eastern Pennsylvania, New Jersey, Delaware and Maryland were represented at the twentieth annual convention of the Pennsylvania Retail Coal Merchants' Association, May 22 and 23 in the Commercial Museum, Philadelphia. Public officials and men prominent in the coal and railroad industries made addresses.

In addition to the regular business sessions there was a dinner at the Bellevue-Stratford, May 22, with Edward J. Cummings, Director of Public Welfare Grakelow and former Director of Public Safety Sheldon F. Potter as the speakers; a luncheon at the Commercial Museum, May 23, with Henry Wolf Bikle, general solicitor of the Pennsylvania R.R., and Howard W. White, former president of the Pennsylvania Retail Coal Merchants' Association, speaking, and a dinner in the Bellevue-Stratford Friday night, with Walter L. Montgomery, vice-president of the association; J. Washington Logue and the Rev. Arthur C. Baldwin making addresses. For the ladies there

Northwest Dock Operators Win Lake Dock Cases

In a decision covering nearly 50 pages the Interstate Commerce Commission has upheld the objections of the plaintiffs in the case of the Northwestern Coal Dock Operators' Association vs. the Chicago & Alton R.R. et al., and has ordered that "the present unduly prejudicial and preferential rates" be withdrawn on or before Aug. 21, 1924.

was a dinner at Valley Forge on May 23, with addresses by Mrs. Maurice J. Crean and Rev. W. Herbert Burk, in addition to a luncheon in the Bellevue-Stratford, when E. E. Bach, director of the Americanization Bureau of the Chamber of Commerce, was the speaker.

Among the important topics considered at the sessions were a general discussion of coal legislation. "Coal Organization," by Samuel L. Kamps, commissioner of the Philadelphia Coal Exchange, and "The Future Anthracite Market," by James B. Neale.

An interesting feature of the convention was an exhibition, open to the public, of heating problems and methods by which the householder may economize in the consumption of fuel. A demonstration of the mechanical problems involved in the delivery of coal also was given.

Dr. Bain to Study British Accident-Prevention Work

Dr. H. Foster Bain, Director of the Bureau of Mines, is en route to England, where he will spend some weeks in the study of the measures employed in that country to prevent or minimize accidents in the coal-mining industry.

Dr. Bain's mission is in furtherance of the agreement effected some months ago between the British Home Office and the U. S. Department of the Interior for the exchange of technical information as to means of preventing mine accidents and the promotion of mine safety conditions, and follows the recent visit to this country of Dr. R. V. Wheeler, Director of the Eskmeals Testing Station, Cumberland, England, for the purpose of observing conditions in the American coal-mining industry.

The Director of the Bureau of Mines will visit the Eskmeals Testing Station and will attend mine-safety conferences of British government officials and mine operators' and miners' representatives. He will devote special attention to the study of the stone dusting method generally employed in England to limit coal-dust explosions. He also will visit a number of the larger coal mines in France for the purpose of noting conditions in these mines. Dr. Bain expects to return to the United States on July 3.

Navy and Marine Corps Award Coal Contracts

The Navy Department awarded contracts, May 26, based on proposals opened May 21, covering the delivery of 300,000 tons of steaming coal at Hampton Roads during the fiscal year beginning July 1, as follows:

Pocahontas Fuel Co., New York, 150,000 tons at \$4.58 per ton; Crozer-Pocahontas Co., Philadelphia, 100,000 tons at \$4.48 per ton; Castner, Curran & Bullitt, Inc., New York, 50,000 tons at \$4.72 per ton. Awards for delivery of coal during the coming fiscal year to other points will be made during the next few days.

Contracts for bituminous coal, for delivery during the coming fiscal year, also were awarded by the U. S. Marine Corps on the basis of proposals opened May 15, as follows: Sixteen thousand tons run of mine for delivery at Paris Island, S. C., Clinchfield Fuel Co., Spartanburg, at \$3.56 per ton f.o.b. mines; 6,000 tons for Quantico, Va., Johnstown Coal & Coke Co., New York, \$4.80 per ton delivered; 3,500 tons for Philadelphia, Maryland Coal & Coke Co., Philadelphia, \$4.385 delivered; 4,000 tons Paris Island, S. C., Clinchfield Fuel Co., \$1.95 f.o.b. mines; 3,000 tons for Quantico, Va., Chesapeake & Virginia Coal Co., Lynchburg, Va., \$4.91 delivered, and 300 tons for Charleston, Clinchfield Fuel Co., \$1.95 per ton f.o.b. mines.

Coal Commission Report To Be Printed

Washington, May 31.—The joint committee on printing finally has been convinced that it will be wise to print the report of the U. S. Coal Commission. As the printing of this report involves a cost of more than \$20,000, the committee declined for several months to authorize the expenditure. Arguments to the effect that it is poor economy to eliminate the expense of harvesting after the crop has been planted finally prevailed with the committee, which has submitted a favorable report. The report, however, must be acted on by each house. As a rule, however, resolutions carrying recommendations of the committee on printing are passed perfunctorily.

Two of the reports, the Cost of Production of Bituminous Coal and the Investment and Profit of Bituminous Operators, were not issued even in mimeographed form. The question has been raised whether these reports are open to public inspection. The policy of Director Smith, of the U. S. Geological Survey, the custodian of the Coal Commission's record, has been to give every possible access to these reports. The manuscripts of all the reports have been in the hands of the Senate committee and of the Public Printer for some months. Duplicate copies, however, have been available for inspection and portions of these reports have been copied during recent months by those interested in them. As some time is certain to elapse before printed copies of the report will be available, Director Smith calls attention to the fact that copies of all the reports may be consulted at his office.

Model Mining Law Chief Objective of House Safety Hearings

Increased Facilities for U. S. Bureau of Mines Also Sought—Recent Mine Disasters Responsible for Action in Congress—Varying Conditions Make Possibility of Standardized Regulations Uncertain

Although the hearings on mine safety which have been conducted recently at Washington by the House committee on mines and mining will not be concluded until Congress reconvenes, anticipating adjournment on or about June 7, it is evident that committee members at present have in mind two definite objectives relating to the subject, namely, increased facilities for the U. S. Bureau of Mines and a model law under which mines on government land shall be operated.

How far the committee will go in recommending legislation to embrace these objectives remains to be seen, as the information desired by the committee has not been developed fully. The hearings thus far held, called by Chairman John M. Robsion after attention had been directed to the general subject by explosions in mines in West Virginia, Pennsylvania and Utah, have been rather in the nature of educating members of the committee as to what constitutes hazards in coal mining. With this as a background, the committee intends to go more deeply into the subject and also to give attention to conditions in metal mines.

Committee members appear convinced that the Bureau of Mines is in a position to do greater good for the mining industry if Congress will provide the money to increase its personnel and to make possible further research and experimentation. Whether it would be possible to draft a law to govern the operation of mines on government land and to serve as a model upon which state laws might be builded is regarded as somewhat uncertain by the committee members in view of testimony that widely differing physical conditions in various sections of the country make a single mining law impracticable, although the desirability of a model law is recognized.

Stresses Government Responsibility

In testifying before the committee, H. Foster Bain, director of the Bureau of Mines, explained the research work of that agency and its educational work in training operators and miners in safety and first-aid work. He stressed the permissible system of the Bureau in testing explosives and mine equipment. Safety precautions must be increased as the upper veins are worked out and the mines are thrust deeper into the earth, Mr. Bain emphasized. He expressed the opinion that the responsibility for mine safety will rest more heavily upon the federal government in the future, because the great coal reserves of the nation are on public land in the West, which will be developed in the future generation as older mines become exhausted.

L. C. Ilsley, electrical engineer of the Bureau of Mines, told the committee the Bureau lacks sufficient personnel to test apparatus as rapidly as it

is offered for this purpose. The use of electrical equipment increases the hazards of coal mining, Mr. Ilsley said, but if it were forbidden the cost of mining would increase heavily. There are about 200,000 pieces of electrical equipment in use in mines of the country which bear the safety label of the Bureau of Mines, the witness said. Safety equipment costs more, he said, but pays in the long run even from the sordid dollars and cents standpoint because of minimizing disaster. The field is a large one, Mr. Ilsley stated, as there is not a single approved motor for pumps, loading machinery or hoists. The Bureau could use to advantage an electrical engineer at every coal mine in the country, the witness said, but hopes in the next fiscal year to be able to add three to its staff. Mr. Ilsley testified that the recent explosion in West Virginia was caused by an unapproved electric coal drill; that in Pennsylvania by an unapproved electric coal-cutting machine, and that in Utah by an unapproved flame safety lamp.

Compares Conditions in Europe

Information regarding conditions in European mines as compared with those in the United States was given the committee by George S. Rice, chief mining engineer of the Bureau. Natural conditions in Europe are more hazardous than here, he said, but greater precautions are taken. Safety precautions are not keeping pace with increased use of mechanical devices in United States mines, Mr. Rice testified. He also declared that there is a lack of technical operating staffs at domestic mines as compared with those abroad.

O. P. Hood, chief mechanical engineer of the Bureau, testified that there is a large field of work in testing mechanical devices which the Bureau has been unable to enter because of lack of funds. The Pittsburgh experiment station has never been used to its capacity for this reason, he stated. The Bureau could use \$100,000 immediately in tests of safety stops, overwind devices and brakes on mine locomotives, Mr. Hood said. He told the committee that economy and efficiency in the use of fuel is highly important also, as tending to reduce consumption and thus reduce the opportunities for mine accidents.

E. A. Holbrook, head of the School of Mines of Pennsylvania State College, who was chairman of the Mine Safety Committee of the U. S. Coal Commission, urged that personal contact in educating miners in safety precautions is the outstanding need. The Bureau of Mines is undermanned and hampered in investigations and research by lack of funds, Dr. Holbrook asserted. He suggested extension of the permissible system. Explosions are dramatic, this witness said, yet are not the principal

Railroads Indorse Move to "Ship Coal Now"

The Car Service Division of the American Railway Association has joined Secretary Hoover's campaign to get large manufacturers to ship their coal early. All of the railroads throughout the country will call attention of their consumers to the conditions.

The transportation companies call attention to the fact that the usual autumn demand for coal comes at the period when railroads are handling the grain movement. In the second place, the volume of coal handled in recent weeks has been far below that moved in the same period of last year. These conditions indicate an immense movement of coal traffic in the fall unless something is done to avoid such congestion.

cause of fatalities in mines. He explained to the committee that the chief hazard in bituminous mines is falls of roof or of coal; secondly, underground transportation, and third, explosions. This information appeared to astound several members of the committee. Many state laws need revision badly, Dr. Holbrook said, declaring that competitive conditions have interfered with progress in this line and that in some instances changes have been opposed by operators and by miners in other cases. Dr. Holbrook urged means of extending the preventive work of the Bureau of Mines.

Edgar Wallace, of the American Federation of Labor, urged more appropriations for the Bureau of Mines and a model federal mining law. He urged that surface water lines be piped into the shafts and that working places and roads be sprinkled. John B. Andrews, national secretary of the Association of Labor Legislation, New York, urged uniform mining laws as far as uniformity may be carried.

The bituminous operators stand ready to co-operate in safety work at all times, Harry L. Gandy, executive secretary of the National Coal Association, told the committee. Personal education of the miners in safety work is necessary, he declared. Miners in some instances have resisted installation of safety devices, Mr. Gandy stated. A uniform law to apply to all coal mines would be impractical, this witness said, owing to varying conditions under which operations must be conducted. He suggested that state universities give instructions in mining according to local conditions. He also stated that state mining laws should apply to all operations, large and small, as some states exempt smaller mines and this tends to make the workers careless. He further suggested that a survey be made to determine whether more mine-rescue stations and cars are needed, and where.

The question of more mine-rescue stations and mine-rescue cars is one that the committee has expressed great interest in and will be taken up more fully later.

Illinois Union Curtails Farrington's Power

Miners who answer more questions than the law requires in applying for work in Illinois mines will be subject to expulsion, according to an amendment to the constitution of the Illinois district union as adopted at Peoria just before their fifth biennial and thirtieth consecutive convention ended May 27. The restriction was an indirect blow at the operators, who, it was complained, are requiring new workmen to fill out a questionnaire before getting work. The convention instructed the miners that they must answer no questions except those required in the miners' certification law and the workmen's compensation law. Delegates complained that operators are rejecting men over 45 years old because they are more expensive risks under the compensation law.

A roll call vote of 496 to 443 deprived President Frank Farrington of power to appoint the nine legal investigators, three auditors and three alternate auditors, one arbitrator, two special accountants, and two legislative committeemen. They will henceforth be subject to election, the first one Dec. 9, 1924.

Efforts to abolish the district executive board failed, as also did efforts to abolish the sub-district organizations. A heated fight over the Ku Klux Klan issue was avoided by the chairman by delaying it till the last half hour of the convention.

The miners voted to investigate the possibilities of the giant power-plant proposal of President Farrington, by which the entire state would be provided with electricity, and Illinois coal be consumed in making it. They also adopted an old-age pension of \$25 monthly for miners 65 or over who have been miners twenty years, ten consecutively in Illinois, and then decided to refer it to the rank and file for approval in a referendum. Funds for the pension would be raised by a 1-per cent assessment of members. The convention voted to join the states of Michigan and Kansas in demanding that Alexander Howat, deposed Kansas district president, be restored all rights and privileges and that an international convention be called to give him a hearing.

C. W. Hunt Succeeds Murdock On Trade Commission

Charles W. Hunt, of Logan, Iowa, secretary of the Iowa Farm Bureau Federation, was nominated by President Coolidge, May 26, to be a member of the Federal Trade Commission, succeeding Victor Murdock, of Kansas, who recently resigned. The Senate confirmed the nomination May 31.

Appointment of Mr. Hunt was recommended by the Iowa delegation in Congress, including Senators Cummins and Brookhart. He also had the endorsement of the Farm Bureau Federation and other farmers' organizations in Iowa, Nebraska and Missouri.

Mitchell Memorial Unveiled At Scranton

Mine workers from all sections of the United States, labor leaders, state and national officers, and men prominent in business and professional life, assembled in Scranton, Pa., on Friday, May 30, to pay tribute to John Mitchell, president of the United Mine Workers at the time of the anthracite strike of 1902. A monument and bronze life-size statue of the famous labor leader was unveiled on the Court House Square following a parade of 10,000 mine workers from the three hard-coal districts. Miss Catherine Mitchell, only daughter of the deceased miners' leader, unveiled the monument.

The memorial was erected by the miners of the anthracite region at a cost of \$75,000. It is constructed of Dummerstone granite from a Vermont quarry. Peter B. Sheridan, of Hazleton, is the designer; Charles Keck, of New York, the sculptor. The granite block originally weighed fourteen tons. Four tons was cut away in designing the memorial. The design shows seven miners at work in the mine, a mule pulling a loaded car and other mine equipment is depicted. On the block under the bronze statue is this inscription: "John Mitchell, 1870-1919."

Lehigh Valley Strike Called Off

At a meeting at West Wyoming May 23 the general grievance committee of the Lehigh Valley Coal Co. voted to call off the strike of 12,000 miners that had been in progress for a week and to send the men back to work Monday morning, May 24. Early May 22 the same committee voted to continue the strike and threatened to call out all maintenance men if their grievance was not adjusted by May 28. It was said that the threat of President Cappellini to appeal to the miners directly and ignore the general grievance committee had much to do with the sudden change.

The strike followed an alleged reduction in wages of 75c. in yardage work at the William A. colliery. The union heads blame the company for such action. Failure of the company to restore the old rate of wages may result in a walkout that will have the sanction of the entire union, it was intimated.

Bureau of Mines Opens Bids

Keen competition for government contracts was again disclosed when bids were opened last week by the Bureau of Mines for the supply of bituminous and anthracite coal for the Government fuel yards during the fiscal year 1925.

Quotations were asked on 239,600 tons of bituminous and 14,990 tons of anthracite, forty-eight proposals being received for the former and six for the latter. A wide range of prices was revealed in some items, the more important being as follows:

One hundred and fifty thousand one hundred tons run of mine: Sugar Creek Coal Sales Co., 20,000 tons at \$2.50; Central Pocahontas Coal Co., \$1.68; Minter Fuel Co., Beckley, W. Va. 54,000 tons at \$2.19; C. G. Blake Co., \$2.35 to \$2.49; Fayette Smokeless Fuel Co., \$2.10 to \$2.20; Smokeless Fuel Co., 60,000 tons at \$2.22; Leckie Coal Co., Columbus, Ohio, 50,000 tons, \$2.18; Johnstown Coal & Coke Co., Johnstown, Pa., \$2.13; Chesapeake & Virginia Coal Co., Lynchburg, Va., 20,000 tons at \$2.22; Lynch & Read, Baltimore, 24,000 tons, \$2.33; Equitable Fuel Co., Baltimore, 29,200 tons, \$2.54; White Oak Coal Co., 75,000 tons, at \$2.24; Lake & Export Coal Corporation, New York, 60,000 tons at \$2.18.

Shipping Board Contracts Awarded on Second Bids

The U. S. Shipping Board at New York on Monday of this week opened bids for furnishing and delivering alongside vessels, and stored in bunkers, operated by the board from New York harbor a maximum of 18,000 gross tons of bituminous coal per month, deliveries to run over a period of 12 months. The specifications called for coal with a minimum of 14,500 B.t.u., bidders to give the name or names of the mines from which the coal is to be shipped. Bids for this tonnage were opened by the board on May 12 and later rejected because of the failure of some of the bidders to name the mines from which coal was to be shipped.

There were seventeen bidders on June 2 and the prices alongside ranged from \$5.19 to \$6, as compared with \$5.17 to \$6.12 on the former opening.

The bidders and prices named follow:

	T.I.B. Over Top	T.I.B. Over Side	F.A.S. according to tonnage taken
Cosgrove & Co.....	\$6.42	\$6.62	\$5.62
McNeil Coal Co.....			5.74
J. H. Weaver & Co.....			\$6.05 to \$6.55
Quemahoning Coal Co.....			5.375-5.23
Morrisdale Coal Co.....			6.00
Coleman & Co.....			5.40
H. B. W. Haff.....			5.99
Horgan Fuel Corp.....			5.34
Eastern Fuel Co.....	6.30	6.50	5.65
Seller Coal Co.....	6.08	6.28	5.43
E. Russell Norton.....	6.40	6.78	
Pattison & Bowns.....	6.52	6.87	5.82
Independent Coal Corp.....	5.89		5.19
Johnstown Coal & Coke Co.....			5.47
Imperial Coal Corp.....			5.50
Dexter & Carpenter, Inc.....			5.59
Steamship Fuel Corp.....			5.51

Practical Pointers For Electrical And Mechanical Men

Selecting Standard Pipes for Columns or Struts

Standard pipes often come in handy for use as columns or struts or for use as push members in transmitting forces. This is because a pipe is strong both in tension and compression.

However, when it comes to calculating columns, it often takes considerable time digging in handbooks, etc., and as result, the use of a pipe is avoided, or a pipe much too large or too small is used, chosen entirely by guess. The pipe that is too small may fail and be the cause of disaster. It is always best, of course, to be on the safe side, but at the same time, one should practice economy.

Table of Pipe Sizes and Loads

Size of Pipes in In.	Column A Maximum Length in In.	Column B	Column C
$\frac{1}{8}$	14.5	826.40	0.07
$\frac{1}{4}$	19.4	617.30	0.12
$\frac{3}{8}$	25.0	480.80	0.17
$\frac{1}{2}$	31.3	383.10	0.25
$\frac{5}{8}$	40.0	300.30	0.33
1	50.6	237.50	0.50
$1\frac{1}{8}$	64.7	185.50	0.67
$1\frac{1}{4}$	75.0	160.50	0.80
2	94.7	126.90	1.07
$2\frac{1}{2}$	114.0	105.30	1.71
3	139.0	86.21	2.24
$3\frac{1}{2}$	161.0	74.63	2.68
4	181.0	66.23	3.18
$4\frac{1}{2}$	202.0	59.52	3.68
5	226.0	53.19	4.32

To assist those who may have occasion to use standard pipes and to make it as easy as possible for them, the following simple table and rules have been developed:

(1) Knowing the load that is to be carried and the length of pipe needed, make a guess as to the size of pipe. Column A in the tables will help in making the guess as it gives the maximum length of pipe that may be used. Thus, never use a $\frac{1}{8}$ -in. pipe as an important column longer than 14.5 in. Never use a 3-in. pipe as an important column longer than 139 in., etc.

(2) Multiply the length of the pipe in inches by the corresponding figure in column B of the table. This product should never be greater than 12,000. If it is greater than 12,000 it means that you have guessed a pipe that is too small. After getting the right size, proceed as follows:

(3) Subtract the product, obtain as stated above, from 19,000. If the difference is equal to or less than 13,000 use it, in 4. If the difference is more than 13,000 use 13,000 in 4.

(4) Multiply by the figure in column C corresponding to the pipe size.

The result is the number of pounds that the pipe will carry as a column,

strut, or push member. If the result is less than the load to be carried, try again, using the next larger pipe size, and so on until the proper and most economical size is selected.

For example, it is desired to support a load of 10,000 pounds at a height of 84 inches. What size of pipe should be used? Following the rules, we do this:

(1) Guessing the size of pipe, column A shows that 84 in. falls between $1\frac{1}{2}$ -in. and 2-in. pipe. We will therefore try a 2-in. pipe.

(2) $84 \times 126.9 = 10,650$. This is less than 12,000 and we will continue.

(3) $19,000 - 10,650 = 8,350$. This is less than 13,000 and we may therefore use it in 4. If the difference were 18,350 we would have to use 13,000 in 4.

(4) $8,350 \times 1.07 = 8,950$ pounds.

Since 8,950 pounds is less than 10,000 pounds a 2-in. pipe is too small. We will therefore recalculate, this time trying a $2\frac{1}{2}$ -in. pipe.

(2) $84 \times 105.3 = 8,850$.

(3) $19,000 - 8,850 = 10,150$.

(4) $10,150 \times 1.71 = 17,370$ pounds.

This shows that a $2\frac{1}{2}$ -in. pipe would be amply safe to hold up 10,000 pounds. It shows that a $2\frac{1}{2}$ -in. pipe is capable of holding almost twice as much as a 2-in. pipe at a height of 84 inches. The small difference in pipe sizes and the great difference in strength indicates the necessity of careful computation and the danger involved in guesswork.

W. F. SCHAPHORST.

How Pipe Joints Can Be Made Truly Tight

So many forms of joints for pipes conveying oil, water or gases have been made that another new type would seem to be almost impossible. It is well known that pipes with screw connections are much more satisfactory than those with clamped joints, especially when carrying liquids or gases which easily flow through small openings.

Ordinarily the ends of pipes are screwed into collars or sockets and the cutting of the threads on the pipes, and particularly in the sockets, must be exact and accurate. For connecting the ends of pipes parallel sockets threaded from each end generally are used. In many cases, and especially where considerable pressures have to be carried, it is customary to give the threaded socket a slight taper from both ends, so that the pipe ends fit more tightly as they are screwed into the sockets.

The new joint-making device shown in the illustration will make it less necessary to taper the threads in the sockets, and is a simple method of obtaining a tightness that will prevent leakage. A machined ring tapered to the same angle as the inside of the pipe ends is placed in the joint. As the internally tapered ends of the pipe are screwed into the socket a radial pressure is exerted by the ring, tending to swell the pipe outward and thereby make an absolutely pressure-tight fit.

Pump Casing Salvaged at Low Cost

The ring shown in the illustration was used to close the leakage space worn between the second and third stage of the centrifugal pump. Most pumps are scrapped when leakage from stage to stage has become too great to permit the pump to oper-

ate efficiently. Many times the unit is in every other way as good as new and considerable money can be saved by making the above simple repair, which was described in detail in the April 3 issue of *Coal Age*.

Leak-Proof Pipe Joint

The machined ring seals the joint between the pipe and sleeve coupling and also expands the end of the pipes so as to close the space along the threads.

The tightness of the joint is therefore not dependent solely on the precision of the screw thread on the pipe and in the socket. Although with the perfected system of the most recent thread-milling machinery great accuracy is insured, the tapered socket is frequently required, but it is thought this new ring joint will generally make this tapering of the socket less necessary.

THE ENGINEER.

Transformers Meet Many Requirements

Instrument transformers are used for two reasons: first, because they make the front of switchboards safe, and second, because they make it possible to use instruments with a reasonable amount of insulation and a reasonable current-carrying capacity. The function of these transformers is to deliver to the instruments and other controlling equipment a current or voltage which shall always be proportional to the primary current or voltage. Generally, the secondary of a high-voltage transformer is designed for about 115 volts, and the secondary of a current transformer for 5 amp.

In connecting instrument transformers to the various types of meters used in conjunction with them, it is necessary to know the relative instantaneous direction of current in the transformer leads. For this reason one primary and one secondary lead of the transformer is usually marked to indicate this polarity. The relation of the marked leads is such that the instantaneous direction of the current in them is the same; that is, toward the transformer in the marked primary lead, and from the transformer in the marked secondary lead, or vice versa.

GROUND INSTRUMENTS FOR SAFETY

All instrument transformers should be grounded on the secondary side as an extra precaution against danger from the high voltage in case the insulation of the transformer should be punctured by lightning, or other abnormal stresses. It is also a general and safe practice to ground the cases of the meters to which the transformers are connected. In polyphase groups of transformer connections any point of the secondary may be grounded, but it is preferable to use a connection where a neutral point or a common wire between the transformers may be readily grounded.

Voltage transformers are used with electrical measuring instruments, synchrosopes, synchronizing apparatus,

protective and regulating relays, and no-voltage and over-voltage trip coils of automatic circuit breakers. One transformer may be used for a number of instruments, or other potential coils at the same time, provided the total current taken by the equipment does not exceed that for which the transformer is designed, and compensated. Voltage transformers of this type usually have a capacity of 200 volt-amperes, but are compensated to give a correct ratio of voltage transformation at 40 volt-amperes, as this is the average load demanded by a voltage transformer. Special transformers may be compensated for any desired load condition up to the full capacity of 200 volt-amperes. The standard secondary voltage is nominally 115 volts.

The instrument voltage transformer is essentially an ordinary constant-potential device especially designed for close regulation, so that the secondary voltage under any condition will be as nearly as possible a fixed percentage of the primary voltage. There are several reasons why the secondary voltage can never be exactly proportional to the primary voltage or exactly opposite to it in phase. The losses in the transformer and the magnetic leakage between the primary and secondary winding must be considered. These two classes of errors, inherent in voltage transformers, namely the ratio error and the phase-angle error are always present. These errors are in part due to the exciting current which is however constant for any given applied voltage. In the design and manufacture of voltage transformers this error may be reduced to a minimum by choosing the best quality of iron and working it at a low magnetic density. That part of the error due to the load current, obviously, varies directly with the load and in turn can be minimized in the manufacture and design of the transformer by making the resistance and reactance of the winding low.

Low Power Factor Affects Meter Accuracy

The effect of the phase displacement of the secondary voltage in the voltage transformer is not important when using meters having only a voltage element and when using protective relays, because these devices depend only upon voltage for their operation. However, when watt-hour meters and similar apparatus are used the indication of these instruments depends not only on the value of the voltage, but also on its relation to the line current, therefore, the phase error has some effect. Obviously, the lower the power factor of the load the greater will be the phase error of the voltage transformer upon this type of instrument. The phase displacement depends not only upon the constants of the transformer but on the power factor of the load to be measured, and, therefore, the effect of this error cannot be compensated in the transformer. In the design of the transformer if the phase displacement is made as small as possible, its effect on reading for commercial purposes is not great.

Grease Cars with Bicycle Pump

The need for the proper lubrication of mine cars should hardly be a matter for argument. Nevertheless, it is not uncommon to see some mine-car bearings almost "crying" for lubrication.

With transportation equipment both expensive in first cost and maintenance our company has saved much money by keeping mine cars well greased, thus making it possible for every locomotive to pull a larger trip of cars than usual.

Grease Gun Lubrication

When one considers the delay occasioned by a dry bearing or the cost of repairing an axle worn out due to lack of proper lubrication, there is ample justification for providing efficient lubricating equipment whether it be by grease or oil.

As soon as we began to give close consideration to the lubrication of car bearings, we realized that the reason why equipment was sometimes inadequately greased or oiled was because the workman found the application of lubricant difficult or arduous. We were not long in learning that the best way to get good results is by making it as easy as possible for the workman.

One of the mechanics' helpers at the mines brought an old bicycle pump to the shop one morning and before long had placed a nozzle on the end suitable for the grade of grease which we use. Now our oiler merely puts the nozzle of the grease gun in a pail of grease and with little effort can lubricate a large number of bearings in a short time.

Another advantage of this gun is that with it the workman need not get smeared with grease. This fact makes it much easier for us to get men for this work.

J. T. WARTON.

Oil Grooves for Locomotive Motor Bearings

In general, it is not considered necessary to have the axle bearing fitted with oil grooves, as these bearings have large surface areas and windows, and are of the split type. However, many men, who believe grooves necessary, use them as an extra precaution against hot axle bearings. Frequently a deep ridge cut in the babbitt at the joint between the upper and lower half of the bearings supplies sufficient extra lubrication.

Production And the Market

Bituminous-Coal Market Marks Time as End of Industrial Depression Approaches

That it requires patience and staying power to an unusual degree to stick in the coal business probably never was exemplified in a more striking manner than at the present time with reports of market conditions from the various centers week after week running the gamut in lugubrious expressions describing the state of business. The end of the depression—or “breathing spell,” as the more optimistic have termed it—seems to be nearing an end, however, the latest report of the Federal Reserve Board indicating that “constructive programs are under consideration in some business circles which a few months ago were content to meet only the demands upon them and make no future plans.” While the activity in some lines is traceable to seasonal increases, the general tone is healthier and it is prophesied that the approaching revival will have more than temporary life.

Government Departments Award Contracts

Regular summer storage of coal by the railroads, as proposed and warmly indorsed by the International Railway Fuel Association last week, is a big step in the direction of stabilization of the industry, which has been so strongly urged by Secretary Hoover. The government is doing its part, the Navy Department having awarded several large contracts last week with others to follow. The Bureau of Mines opened bids May 28 for 239,600 tons of bituminous coal and 14,990 tons of anthracite, the quotations of soft coal varying from \$1.69 to \$2.54 f.o.b. mine. Meanwhile the coal trade is marking time, there being little change in either demand, prices or output.

Coal Age Index of spot prices of bituminous coal advanced 2 points during the last week, registering 169 on June 2, the corresponding price being \$2.04. This compares with \$2.02 on May 26.

Dumpings of coal for all accounts at Hampton Roads

during the week ended May 29 amounted to 371,564 net tons, compared with 241,490 tons dumped during the previous week. Coal dumped at Lake Erie ports during the week ended May 31, according to the Ore & Coal Exchange, were as follows: Cargo, 625,440 net tons; fuel, 39,640 tons. The figures for the preceding week were 529,883 tons of cargo coal and 35,748 tons of fuel coal.

Output of bituminous coal during the week ended May 24, according to the Geological Survey, was 7,155,000 net tons, an increase of 124,000 tons over

the week before, when 7,031,000 tons was produced. Production of anthracite fell off slightly, the output being 1,850,000 net tons, compared with 1,898,000 tons during the week ended May 17.

The anthracite market is beginning to show unmistakable evidences of a tendency to slow down. Demand has slackened and independents are preparing for cancellations. Stove continues to lead the van, but the call for egg, chestnut and pea is noticeably tapering off. While the output of hard coal is smaller than last year it is sufficient to satisfy immediate requirements. A slightly stronger note was apparent as a result of the mines being idle over the holiday.

Estimates of Production

(In Net Tons)

BITUMINOUS

	1923	1924

(a) Revised from last report. (b) Subject to revision. (c) Minus one day's production to equalize number of days in the two years.

Midwest Expects Improvement

There was a hopeful undertone to the mournful lay the coal trade in the Midwest region was singing just before June 1. A good many men were of the impression that the demand for coal was due for a slow but steady pick-up after that date. Stockpiles are still high but there is more indication of summer buying now than there was a week ago. The urgings of Secretary Hoover and others are having a certain effect.

Production in Illinois last week would have registered a slight improvement had it not been for the shutdown of two busy mines in the central Illinois field caused by a labor dispute. Indiana production also appears to have reached rock bottom and is ready to rebound. Both states are so low, however, that a little business makes a big showing.

In the Chicago region a steady though thin dribble of domestic business has continued, due to unseasonably cool weather. Smokeless lump and egg has had a small market at a mine price of \$3.25@3.50, which is an improvement of 25c., and mine run has reached that territory at \$2, but with no indication of a June 1 rise. Yards are taking the customary amount of hard coal for this time of year.

Conditions are unusually quiet at St. Louis. There seems to be no domestic business moving excepting in small quantities for current needs. Rain and cool weather have developed a little country business, but the storage of coal on the part of the consumer for next winter has not started, although indications are that it will pick up in June.

Kentucky Remains Somnolent

Demand for Kentucky coal at Louisville continues quiet, movement of western Kentucky coal being very slow, as retailers are not buying and small industrial demand is not heavy. Eastern Kentucky isn't getting much lake business as yet, as movement has been sluggish and is not expected to get well under way for another thirty days. Eastern Kentucky, however, is busier than most fields, due to low non-union scale of wages and low selling price.

The situation in the western Kentucky field remains unchanged, there being a generally slow demand for all grades, but with some improvement noted in stove sizes from the South. Screenings are scarce and selling at about the mine-run price, while large egg, block and lump sizes are a bit quiet. Strike benefits are now being rationed out to the miners in the affected portion of the field. The

Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines

	June 2 1924	May 26 1924	May 19 1923	June 4 1923
Index	169	167	169	215
Weighted average price.....	\$2.04	\$2.02	\$2.05	\$2.60

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913-1918," published by the Geological Survey and the War Industries Board.

non-union, stripper and other operations in the field are not busy, in spite of the large number of mines that are down.

West Virginia operators discern a fundamental improvement in conditions, based on gradually increased production in some sections, but depression still prevails in many sections. Virginia mines are producing a little less coal than for the corresponding period of May and yet market losses are not any heavier than they have been.

Northwest Gets Busy

The one significant feature of the coal market at the Head-of-the-Lakes is the better temper which prevails among all dock men. It is not optimism exactly but merely the better feeling produced by more hustling for orders. Old stocks must be moved to avoid deterioration and fire losses. For the first time in months the coal market is really awake, and it is probable that business will be done. Duluth coal men predict that much of the anthracite trade which was lost at Twin Cities will be brought back into the fold. A high-spot survey has brought to light unusually light stocks in northern consumers' bins, and the trade looks for orders to fill soon.

The market is fairly stable at present prices. One significant increase during the week is of Pocahontas to \$7.25 for lump, \$5.50 for run of mine and \$4.50 for screenings. This shows that many docks expect consumers to use smokeless soft as an anthracite substitute next winter.

Receipts at Duluth-Superior docks showed marked improvement last week, when 25 cargoes, three of them hard coal, were landed. This compares with 18 the week before. Since the opening of navigation 591,660 tons of soft and 126,930 tons of hard coal have been landed.

Iron range towns have lately come into the market for lots of coal ranging from 5,000 to 20,000 tons, mainly for utilities. Bids on these contracts will be opened the first week in June.

There is very little business at Milwaukee. A moderate demand for anthracite and Pocahontas is all there is. Coal is coming quite steadily by lake. The receipts by vessel thus far since the season opened aggregate 131,908 tons of anthracite and 282,499 tons of soft coal.

Southwest Bestirs Itself

Operators began the last week in May to open up mines in Arkansas and take orders for semi-anthracite in anticipation of the reduction in freight rates effective June 5. A slight increase in activity is noticeable also in Kansas, where a few more mines, both shaft and shovel, have been reopened in the last week, and where others are expected to be reopened before the middle of June. The resumption of mining is partly due to the current demand and partly in preparation for the storage market, which will open soon, and for the threshing market, which will open in June. Kansas City prices are: Kansas lump, \$4.50; nut, \$4; mine run, \$3.50; screenings, \$2.50; Arkansas semi-anthracite lump, \$5.50@6; mine run, \$3.50; screenings, \$2; Henrietta (Okla.) lump, \$5.50; nut, \$3.75; mine run, \$3.50; screenings, \$2.50.

Colorado buyers were inactive during the week, despite the fact that everyone was expecting an advance in prices June 1. Mines worked on an average of 20 hours last week and the operators' reports show that 46 per cent of the working time lost was attributed to "no market." With the miners' resumption of work at the Broadhead mine all labor disorders have been eradicated for the time being.

In Utah the coal industry is marking time. Production figures show mines are working below 30 per cent of full-time capacity. Dealers are making an effort to get their customers to put in their winter coal now, but the response is poor.

Undertone Stronger at Cincinnati

June prices of smokeless at Cincinnati are up 25c. for lump and egg, and first of the month bookings are said to be heavier than May orders. While the prepared sizes are moving in good shape there is not the ready market for screenings, and some sales have been made down to \$1.50. The undertone continues to be stronger. Movement to the lakes is 35 to 40 per cent behind normal, but there is no rush to get coal for that movement. Utilities are not in the market as they might be but the closing of several large railroad contracts within the last two or three weeks shows that pressure that formerly kept driving the market down has been released. A slight recovery in the price of slack and run of mine resulted. There is little or no change in retail prices. River business continues good with a high stage flowing. Kanawha tonnages show an increase. Specialized coals are quoted as follows: Egg, \$2.50@3; block, \$3.25@3.75.

The trade continues rather dull in Columbus and central Ohio. Buying is limited, as neither retailers nor steam users are showing any disposition to stock up for the future. The weather has mitigated against a more lively domestic trade. Dealers have been making rather low prices in order to clean up and as a result quotations are irregular. Some smokeless grades, including Pocahontas, are being sold and there also is a demand for splints and Kentucky grades. Ohio-mined coals are extremely dull. Steam business is quiet as reserves in the hands of some of the larger users are still heavy. Contracting is not brisk, as most of the steam users are content to buy from the open market. One of the features is the shrinkage of distress coal due to the closing down of more mines. Lake trade is showing signs of becoming more active, but contracting for lake shipment is not strong.

The trade at Cleveland is pessimistic, seeing little immediate hope for material improvement. Inquiries are scarce, and producers are of the opinion that the mines may as well be closed completely as to operate only one or two days per week. Almost one-half of the mines in the eastern Ohio field are closed down indefinitely, and no attempt will be made to reopen until the market is much improved. During the week ended May 24th the eastern Ohio No. 8 Field produced 253,000 tons, or about 36 per cent of the combined potential capacity of the district, estimated at 700,000 tons. This is a gain of 5,000 tons over the preceding

week, but this increase is without significance as a market factor, because it was due largely to a slightly accelerated production of coal for shipment to the lake by operators with dock interests at the head of the lakes.

Demand for coal at Pittsburgh continues extremely poor. Steel mill operations continue to decrease, as buyers of steel are liquidating stocks. There are no signs marketwise of increased interest on the part of lake snippers. Wage reductions by independent operators in the Connellsville region, it is thought may influence the Pittsburgh coal market. Strip mines are crushing considerable coal, which accounts for increased offerings of slack.

The Buffalo market is still quiet, with not much prospect of early improvement. Demand seems even poorer than it was, as consumers continue to rely on their stock piles.

Pessimism Enshrouds New England

In New England the market for steam coal shows no sign of recovery. Prices drag along much as they have for the past 60 days and it cannot be said that the trade is at all encouraged over the prospect. In the textile centers, like Lowell, Lawrence, Fall River and New Bedford, there is a pronounced pessimistic tone, and from these sources and the shoe industry there is today almost no inquiry for coal.

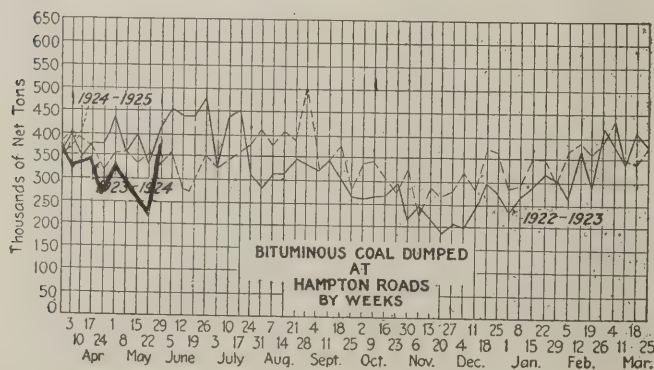

At Hampton Roads there is little change. Some days the spot market improves to a degree, but invariably thus far these periods have been followed by dull spells that bring down the average of both tonnage and price. No. 1 coals are still being sold down to \$4.35, with an occasional sale made at \$4.40, these figures being per gross ton f.o.b. vessel. A few agencies have set \$4.50 as an asking price; no sales are reported at that level. No. 2 coals can be had at prices down to \$4. Output fluctuates from week to week with the trend of prices, but practically all the time there are considerable accumulations at the piers.

All-rail there is the same stagnant market. Receipts week by week show heavy declines compared with other years, and there is today no rosy outlook for coals in central Pennsylvania so far as this territory is concerned. Via the New York and Philadelphia piers there is no noticeable improvement.

Inquiries Drop in Atlantic Seaboard Markets

There has been a falling off in inquiries at New York and the prospects of increased business during this month are not as bright as they were. Buyers continue to hold to the policy of caution which they have followed for many weeks. Receipts at the local tidewater piers increased to around 1,500 cars some days during the past week and there was an accumulation of coal, but not in sufficient quantities to lower prices. Demand was slow, however, and it required hard work to keep the coal moving. There were reports current that a 50,000-ton order for foreign shipment had been obtained by a local house but it could not be confirmed. Inquiry, however, points to some new business with South America.

Faint signs are discernible in Philadelphia that some consumers are inclined to take in a little stock, but even the most hopeful producer is not willing to admit that it is likely to become general soon. General industrial conditions are unsatisfactory, especially in textiles. Manufacturers expect a favorable turn soon, but the unseasonable weather all spring has held them back and they are waiting for warm weather to move their goods and get back to longer working time. The only real demand is for slack. The spot market remains unchanged as to price, and the market is firm at present figures.

Inquiries are beginning to come in at Baltimore for contract delivery over the late summer, autumn and winter. The competition in selling is still so keen and mines are still selling at such a low price to the jobbing trade that so far there is little response in price raise either in the open market or on contracts, which are being made at "ruinous rates." The spot market shows but little change, demand being moderate and competition keen. The export situation continues to drag, only seven ships with a total of but 25,399 tons cargo and 2,341 tons in bunkers loading from May 1 to 23.

Buying in the Birmingham market is very slow, with consumers indifferent and taking as little as they can get by with, as a rule. Slight price reductions on some grades as a result of wage adjustments recently made, has not stimulated buying so far, even on the grades affected, emphasizing the fact that the trade inactivity is not attributable to the price of fuel but rather to restricted industrial requirements and a disinclination to stock.

Anthracite Business Slowing Down

There are many indications of a slight slump in the New York anthracite market. Demand has slackened and some of the smaller operators and sales agents of independent coals are taking orders at less than last week's quotations. One producer announces prices for some of the domestic coals 10c. lower for June than for May and he is said to have orders booked for June and July delivery at these prices. Stove continues to lead in demand. Both egg and chestnut are accumulating in some quarters and pea coal is moving much more slowly. Retail dealers' yards are well filled. Independent operators are well booked ahead but with demand subsiding cancellations are looked for. Some shippers of independent coals had an oversupply of chestnut at tidewater which they were forced to load into boats in order to save demurrage charges. Demand for steam sizes has already slowed down considerably. Only the better grades of independent No. 1 buckwheat and rice are quoted at full company circular. Barley continues to be the most active of these coals. Hard-coal business at Philadelphia is slowing down. Retailers have few orders on their books for cellar filling and orders are just straggling in. There is still quite a shortage of stove and shippers are being urged for deliveries.

Coke Output Slumps Again

The general reduction of wages inaugurated by the independent coke operators in the Connellsville region to the scale of Nov. 10, 1917, is not proceeding as rapidly as was expected. This, however, does not mean that the reduction is any less certain to be general among the independents in operation, for not a few are entirely closed. Output of beehive coke again slumped during the week ended May 24, when 159,000 net tons was produced, compared with 189,000 tons during the previous week, according to corrected returns by the Geological Survey.

Foreign Market And Export News

British Market Notes Stronger Tone; Inquiry and Output Better

The South Wales market has been slow in recovery by reason of a number of difficulties, chief of which is labor. Coupled with the labor trouble is the problematical effect of the new wages on prices and the strike in the Ruhr. The settlement of the wage question for the next twelve months is an encouraging influence, but fifteen thousand miners are still on strike, owing to a local dispute. The tone of the market has improved slightly due to an increase in inquiry in anticipation of the holidays. Exports also are expanding, though supplies are ample and prices are holding barely steady.

European inquiry on the Newcastle market has improved somewhat, though the market is in a state of great uncertainty, due to the same factors that have influenced South Wales. There has been considerable anxiety as to the possible result of the negotiations between operators and miners. The Norwegian State Rys. have placed orders aggregating 35,000 tons of steams at prices between 28s. and 28s., while two other contracts for 7,000 tons of best steams and 10,000 tons of steam smalls have been placed.

A cable to *Coal Age* states that the coal production by British mines during the week ended May 17 was 5,659,000 tons, according to the official reports. This compares with an output of 5,220,000 tons during the previous week.

Prices Stiffen at Hampton Roads, New Business Scarce

Demand for coal at Hampton Roads having reached rock bottom, the piers turned in the lowest monthly dumping record for a year, though there was a marked increase last week. Prices have stiffened somewhat due to shortage at the piers rather than to demand.

Foreign business, except for a sporadic movement to South America, is without feature, bunkers holding their own chiefly on account of old con-

tracts, with little or no new business reported. New England trade has slumped materially and the opening of lake shipments did not help trade here.

Supplies at the piers has been lower than for a great many months, operations in southwest Virginia and elsewhere having curtailed their output substantially because the market did not make it attractive to operate.

French Industrial Demand Holds; House Coal Orders Slacken

The French coal market is almost stationary. Orders for household coals have slackened at the French mines, but the demand for industrial fuels remains satisfactory.

Imports from Great Britain have been better of late, especially when the rates of sterling stood around 67@68 fr.; besides most of the f.o.b. prices at the shipping docks have been lowered, the result being that certain grades of British coals have been selling here at either equal or even lower prices than French coals. Since the last rise of sterling, however, the situation has changed.

The Belgian miners have accepted a reduction in wages and a strike has been averted. There is still much difficulty encountered in marketing the output, however. Although prices have not been officially changed, rebates of 10 to 20 fr. per ton can be obtained on sized products for transportation on barges.

Rail traffic has been good and freight is being maintained at 22 fr. Bethune-Paris.

Deliveries of indemnity fuel to the O.R.C.A. from the Ruhr for France and Luxemburg during April included 524,600 tons of coal, 729,400 tons of coke and 47,100 tons of lignite briquets, a total of 1,301,100 tons, or an average of 43,370 tons daily. During the first two weeks of May the daily average was 19,000 tons.

News Items From Field and Trade

ALABAMA

Reports from Jasper, Walker County, state that the Deepwater Coal Co., recently organized by L. B. Musgrove and associates, is preparing to make drillings on the Black Creek seam with a view to locating openings for the development of the property.

The Etowah Investment Co. has leased coal properties from the Raccoon Coal Co., of Gadsden, and will make openings on lands located in the western part of the county.

ALASKA

Operation of a first-aid and mine rescue car to serve all the mines located along the Alaska R.R. in the Territory of Alaska has been arranged by Secretary Work of the Interior Department. A railroad car is to be turned over to the Bureau of Mines by the railroad and equipped with oxygen-breathing apparatus, oxygen tanks, first-aid material and fire-fighting equipment, in addition to living quarters for the safety men in charge. This car will be prepared to answer emergency calls. The plan of safeguarding lives of Alaskan miners was initiated by General Manager Landis of the Alaska R.R. and D. J. Parker, chief engineer of the mine-safety service of the Bureau of Mines, who is looking over the bureau's work in safety instruction in Alaska.

COLORADO

J. B. Elby, government geologist, of Washington, D. C., was in Denver late in May en route to western Colorado and eastern Wyoming, where he will survey coal fields and oil deposits.

ILLINOIS

The Inter-State Fuel & Power Corporation, 313 North Main St., Decatur, has been incorporated with capital of \$500,000 to mine and deal in coal and other fuels. The incorporators are M. Harvell, S. O. Harvell, and H. O. Hood.

A meeting of the stockholders and certificate holders of the Lovington Coal Mining Co., of Lovington, was held a few days ago in Decatur and \$20,000 of the necessary \$40,000 was subscribed. The work will be continued and it is believed that the mine will be reopened and operated.

Clarence Bean, for the past year superintendent of the two mines of the Jewel Coal & Mining Co. at Du Quoin, has resigned to be head of a mine of the Willow Creek Coal Co. at Terre Haute, Ind. Fred W. Price, formerly of the

Tamaroa, Little Muddy Coal Co., Tamaroa, has been appointed to succeed Mr. Bean with the Jewel concern.

Jewel No. 2 of the Jewel Coal & Mining Co., of Du Quoin, began operations last week. A new crusher was moved from Mine No. 1 to No. 2 and will be used at this time to crush the lump and egg coal into smaller sizes.

The Hart-Williams mine near Benton has been sealed up and probably will not be operated again. The mine, which is one of the oldest large mines in the state was operated for years by the Hart-Williams Coal Co. of Benton. The machinery and most of the equipment was taken over by Pollack Bros., of Herrin, largest junk and machinery dealers in that section of the state.

KENTUCKY

State Banking Commissioner James P. Lewis, Frankfort, has authorized the Defiance Coal Co., of Lexington, to sell \$100,000 of preferred stock in the state, under the blue sky law regulations.

It was reported from Owensboro on May 22, that United Mine Workers of District 23, who have been on strike since April 15, were to start receiving strike relief on Monday, May 26, announcement to this effect having been made by Lonnie Jackson, district president at Central City, who stated that the international finance agent would arrive on Monday to supervise distribution of supplies. Food and supplies will be issued from commissaries in various parts of the district, and about \$25,000 is to be expended in the first relief.

Abner Lunsford, of Stone, who has charge of Henry Ford's coal interests in Kentucky and West Virginia, was recently elected a delegate to the Democratic National Convention which will be held in New York in June.

MASSACHUSETTS

Boston has awarded a contract for 14,000 tons of semi-bituminous coal for the police, public buildings and other departments to the Metropolitan Coal Co. on proposals advertised twice. The coal for the public buildings department will cost \$6.32 a ton and that for the police and fire boats \$5.95. The Mayor asserts that a saving of nearly \$2,000 was effected on the second bids.

OHIO

The mines of the New Lexington Coal Co., the Silver Fox Coal Co., the Caledonia Coal Co. and mine No. 19 of the Sunday Creek Coal Co., in the vicinity of New Lexington, are resum-

ing operations, following a suspension in most cases of about six months.

The Chesapeake & Virginian Coal Co., Inc., announces the appointment, effective May 12, of Thomas R. Morgan, formerly sales manager of the Webb Fuel Co., as western manager, located at 1322 Union Trust Building, Cincinnati.

Ohio coal miners are being urged to produce more coarse coal and less slack as the result of a conference recently at New Philadelphia between coal operators and Ohio officials of the United Mine Workers. The conference was called by W. H. Haskins, Coshocton, operators' commission to improve Ohio coal in competition with West Virginia and Kentucky coal. Lee Hall, president of the Ohio miners, and G. A. Savage, secretary, are said to have agreed to circularize locals in an effort to improve the quality of coal. Half of the 21,000 Ohio miners are idle, but little relief will be felt until a huge reserve of stock is consumed, Mr. Hall said.

The Central States Coal Co., of Toledo, Chas. T. Harther, president, and S. T. Walbolt, general manager, advise that a reorganization of the Defiance Coal Mining Co., in which they are now financially interested, was completed in their office at Toledo, May 28. The following officers were elected: C. P. Harley, president; W. G. Jarvis, vice-president; Carel Robinson, secretary-treasurer. Mr. Robinson is associated with the Central States Coal Co. and manages the other mines in which that company is interested, viz: Rockhouse Coal Co., Blackey, Ky.; the Solar Coal Co., Conda, Ky., and the Bermuda Coal Co., at Chavies, Ky.

PENNSYLVANIA

Payment last week by the Glen Alden Coal Co. of state taxes amounting to \$922,231 to Auditor General Samuel S. Lewis brought the total receipts for the first year of the present biennium up to \$65,633,679.90. More than a year ago the Auditor General predicted that the receipts for the present appropriation year, ending May 31, would surpass \$65,000,000.

Work has been started by Maurice Sullivan, contractor, on the dismantling of the Sloan breaker and shaft of the Glen Alden Coal Company. The timbers and machinery are being salvaged. It will take several months to complete the contract.

The Bureau of Mines, Pittsburgh station, proposes to broadcast a message to the chapters of the Joseph A. Holmes Safety Association at 8:30 p.m. (daylight saving), June 6 and 20. A.

C. Fieldner, superintendent of the Pittsburgh Station, will deliver the first address, which will be in reference to the service being rendered by the Pittsburgh station of the safety association. Mr. T. T. Read, safety service director, who became safety service director June 1, will make the second talk, on the safety work of the Bureau of Mines.

The Baton Coal Co. (George S. Baton), First National Bank Building, Pittsburgh, has taken charge for the Union Trust Co. of the mines acquired at the sale by the receivers of the property of the American Coke Corporation several months ago. The properties consist of American mines Nos. 1 and 2 and beehive ovens at Linn, near Brownsville, and the Sunshine Mine at Martin, both in Fayette County. The mines at Linn are nearly worked out and the Baton company is withdrawing the pumps and will allow them to fill with water, dispensing with the services of the superintendent at that plant, William H. Hardy. The property will be left in charge of a watchman. None of the above mentioned plants has operated since being acquired by the Union Trust Co.

A four weeks' course in coal mining, for which 25 men will be accepted as students, will be given beginning June 16 by the Carnegie Institute of Technology, Pittsburgh, in co-operation with the U. S. Bureau of Mines experiment station. The course, the subjects for which will be prepared with the advice of a committee of coal operators, will include sessions each morning at the institute in mine laws and regulations, ventilation, gases, safety lamps, methods of working, explosives, timbering and mine arithmetic. Afternoon sessions will be held at the experiment station in mine rescue and first aid, coal-dust explosion demonstrations and permissible explosion demonstrations, with lectures. A special examination for firebosses, assistant mine foremen and mine foremen will be given at the station by the State Department of Mines at the close of the course, July 16, 17 and 18.

A class of 247 took the examination in Johnstown last week for first- and second-grade mine foremen certificates and 100 applied for fireboss certificates. The board of examiners is composed of Mine Inspector Nicholas Evans, of Johnstown; George W. Wilkes, of Windber, mine superintendent of the Berwind White Coal Mining Co., and Robert Jones, a miner, of Windber. The board was assisted by John I. Thomas and Thomas D. Williams, both of Johnstown. Additional examinations will be held at State College and in Pittsburgh following the close of the short courses in mining at Carnegie Tech. and State College on July 15.

TENNESSEE

O. P. Pile, Chief Mine Inspector, and the Examining Board will hold a mine foremen's examination in the Federal Building, Knoxville, June 3, 4, 5, 1924.

WASHINGTON, D. C.

C. Lorimer Colburn, who is promoting the Joseph A. Holmes Safety Associa-

tion work for the U. S. Bureau of Mines, will soon make a trip to Norton, Va.; Knoxville, Tenn.; Birmingham, Ala.; Baton Rouge, La.; Bartlesville and McAlester, Okla.; St. Louis, Mo.; southern Illinois and Vincennes, Ind., thence returning to Pittsburgh.

WASHINGTON

Examination and prospecting of six sections of land south of Wilkeson and adjoining that property, under the direction of Mel C. Butler, proved the continuation of the Wilkeson seams and also revealed three additional seams, making seven seams of high-grade of coking coal containing considerably over 25,000,000 tons. The Pacific Coke & Coal Co., will develop the property through a tunnel some two miles long which will cut all the seams on both dips. The company expects to produce 2,000 tons of washed coal per day. E. F. Lawson is manager of the company and Mr. Butler is engineer-superintendent.

Ira Clemens

President of the Clemens Coal Co., Pittsburgh, Kan., and one of the new vice-presidents of the National Coal Association named at the Cincinnati meeting.

WEST VIRGINIA

The Coal River Collieries Co. has increased its capitalization from \$2,500,000 to \$5,000,000 and the American Eagle Colliery from \$400,000 to \$500,000.

Construction work has been started by the Philadelphia & Cleveland Coal Co., the Logan Dock Co. and I. R. Ingersoll, of Cleveland, on a coal dock for the Ohio River at Huntington, to cost approximately \$600,000.

The following coal companies have been dissolved as corporations: Thomas Smokeless Coal Co., Plum Eagle Coal Co., High & Low Volatile Fuel Co. The Anchor Coal Mining Company has been dissolved by deed of sale. The New River Collieries company has withdrawn from the state.

The property of the Barbara Mining Company on Scott's Run in the Monongalia field was sold at public auction on May 24. This is a fully equipped mining plant operating in the Waynesburg seam. The sale included com-

pany houses, tipples, siding, trackage and other mining equipment and machinery.

D. C. Jones has been designated as receiver for the Carry-On Coal Co., a Huntington corporation capitalized at \$200,000, by Judge Thomas S. Shepherd in the Circuit Court of Cabell County. H. S. Brown, who with his wife, owns a controlling interest in the company, asked that a receivership be appointed in connection with a pending chancery suit against the company.

At a special convention of the miners of District No. 17 held at Charleston a resolution was adopted calling for abolition of the four subdistricts in the district, subject to a referendum of the members of the union in the district, in order to reduce operating expenses. At the same time a policy was formulated providing for the strictest economy possible in the conduct of the affairs of the district. Such action became necessary in order to meet conditions now confronting the organization in its effort to maintain its existence in northern and southern West Virginia, for with membership greatly reduced the union has not been able to pay any strike benefits where circumstances appeared to call for it.

The statement in *Coal Age* of May 22 that the Elkhorn Piney Coal Mining Co. had closed its Huntington offices was a mistake. The company has curtailed the personnel of its Huntington office but the office is still in operation. D. T. MacLeod, who resigned as of Jan. 1, 1924, has been superseded by George W. Mackie.

The Circuit Court of Monongalia County has sustained the exceptions to the answer of the defendant in the injunction proceedings of the Chaplin Collieries Co. against the Pursglove Coal Mining Co. involving the right of the defendant company to mine all of the coal beneath the Sewickley coal of the plaintiff company. This case, as has already been stated, involves the mining laws of West Virginia as well as the question of mine rights.

After a delay of about two months, the Bertha-Consumers Company has signed the Baltimore agreement. The contract between the company and the union was signed at Pittsburgh at a meeting between John H. Jones, president of the company, and Percy Tetlow and others representing the United Mine Workers. Inasmuch as the contract is effective at once, it is understood that President Jones contemplates a resumption of operations at the Bertha mine at Madsville in the near future.

Receivership proceedings having been instituted against the Beckley Pocahontas Coal Co. in Cabell county. A. P. Grady, of Huntington, has been appointed receiver by the court. Those familiar with the case are inclined to believe that the company will be able to right itself and that its affairs will be worked out satisfactorily. This company has its mines at Besoco, in Raleigh County, on the Stone Coal Branch of the Virginian Ry. as well as on the Chesapeake & Ohio Ry. There are about 2,000 acres of smokeless coal

under lease, with about 18,000,000 tons available. Under present equipment the property is able to produce from 18,000 to 20,000 tons of coal per month.

The Consolidation Coal Co. adopted a centralized system of purchasing, effective June 1, by which this phase of the company's business is conducted from the company's main offices in the Watson Building, Fairmont. This will eliminate the division purchasing offices at Somerset, Pa., Frostburg, Md., Jenkins and Van Lear, Ky., and Coalwood, W. Va., all of which are grouped in Huntington with A. T. Watson as general purchasing agent and F. C. Davis as assistant purchasing agent.

WYOMING

Miners for the Rock Island Coal & Mining Co. at Hartshorne struck May 20 when the company refused to permit them to go back to open-flame carbide lamps. Electric lamps had been adopted but ruled against by Ed. Boyle, mine inspector. The company has appealed to the federal court to enjoin Boyle from interfering with the safety program.

Promotions in the personnel of the Union Pacific Coal Co. have been made by President Eugene McAuliffe to fill the vacancy caused by the death of E. S. Brooks. George B. Pryde moves up from general superintendent to the vice-presidency and general management of mines, A. W. Dickinson is advanced from safety engineer to general superintendent and John A. Smith from engineer to safety engineer.

CANADA

Sir Stephenson H. Kent and Sir John Scott Hindley, British coal dealers, are in Montreal with a view of establishing in connection with local distributors a new company to deal with the Canadian trade. It will be known as the British Canadian Coal Co. and will be operated

in connection with the Canadian Industrial Coal Co., Ltd., Sir Stephenson Kent said in an interview: "We do not anticipate sending over sufficient quantities to appreciably affect the amounts received from American mines." He pointed out that the English collieries must have a market to enable them to maintain steady production. The mines being made much deeper than those of the United States, requiring large capital and heavy overhead charges, could not be worked on short time with low production without entailing a loss.

Following a conference in Toronto between Premier Ferguson and various interests concerned in shipping Alberta coal to Ontario, it was announced that Ontario and Alberta jointly would submit a new proposal to the Canadian National Rys. to the effect that two solid trainloads of Alberta fuel be sent eastward and that these trainloads be made a practical test of cost per ton of transportation.

At last account there was no indication of any termination of the deadlock existing between district No. 18 of the United Mine Workers, embracing Alberta and eastern British Columbia, and the Western Canada Coal Operators' Association. The miners have been on strike since April 1 and neither side is inclined to make any move in the direction of conciliation or the reopening of negotiations.

The Princeton, (B. C.) Colliery Co. has been incorporated in London, with a capital of £1,100, to take over and operate the Princeton Coal & Land Co.'s coal mines and town sites. This appears to be a reorganization with nominal capitalization. The Princeton Coal & Land Co. is capitalized at \$1,000,000, and for several years has been operating a small coal mine and developing prospects near Princeton, besides selling land in the town.

The Mineral Tax Act of the Province of Alberta has been disallowed by the

Dominion Government on the ground that it interfered with Dominion rights and was in conflict with Dominion policy and interests. The public lands of the western provinces belong to the federal government and the mineral rights are reserved when the lands are disposed of. The Alberta act provides for the collection of the tax by distraint upon the equipment and plant of the lessee, which often is the only security the federal government has for the payment of rent or royalties. The act was therefore declared *ultra vires*.

New Companies

The new Bevier Coal Co., Cleaton, Ky., capital \$100,000, has been chartered by John W. Price, John W. Bastin and R. S. Lytle.

The Paramount Fuel Co. of Illinois, with a capital of \$30,000, has filed articles of incorporation in Missouri, with headquarters in Kansas City and with a capital of \$10,000. The company will mine coal and sell coal and coke. The principal agent in Missouri is Julius C. Smith, of 524 Dwight Building, Kansas City.

The Valentine Coal Co., of Kansas has filed articles of incorporation with the Secretary of State at Jefferson City, for Missouri, with a capital of \$60,000 and headquarters in Worland. The company will carry on a business of mining, stripping and selling coal. A. A. Grimmel of Worland is the principal agent in Missouri.

The Missouri-Oklahoma Fuel Co. has been incorporated at Muskogee, Okla. with a capital of \$100,000. The incorporators are William McKinnon, of Kanima; E. H. Mills, of Springfield, Mo., and E. D. Holley, of Stigler, Okla.

The Vanzandt Coal Co. has been incorporated at Gadsden, Ala., with a capital stock of \$2,000 and will begin mining operations near Altoona. W. A. Booker is president and W. M. Booker, secretary-treasurer.

The Portage Coal Co., Kenmore, Ohio, has been chartered with an authorized capital of \$125,000 to mine coal and deal in coal and coke at both wholesale and retail. Incorporators are S. M. Ranger, B. R. Felt, D. S. Felt, S. H. DeLong and L. C. Wogan.

A Dominion charter has been granted to the McMaster Coal & Transportation Co., Ltd., Montreal, Canada, who engage in business as manufacturers, operators and dealers in coal and all its byproducts. The authorized capital is \$50,000 and the incorporators are Montreal lawyers.

Industrial Notes

The Pulaski Iron Co., of Eckman, W. Va., has completed arrangements for the installation of a "Rands" shaker loading boom to be used at the tippie of the company at Eckman. The contract for the installation has been awarded the Roberts & Schaefer Co., of Chicago.

Construction work has been started at Whitman, in the Logan county field, on a new steel tippie which will rank as one of the best in southern West Virginia. It is to cost approximately \$100,000 and will replace a wooden structure now in use. The tippie will be ready for operation about Sept. 1.

The Blackwood Coal & Coke Co., of Blackwood, Va., has contracted with the Roberts & Schaefer Co., for the complete installation of concrete storage bins and tippie at their new operation at Calvin, Va. The tippie will be complete with revolving dump and reinforced concrete storage bins of a capacity of 2,500 tons. In connection with the storage bins will be built a steel Marcus tippie.

L. D. Albin, formerly general sales manager of the Ingersoll-Rand Co., 11 Broadway, New York City, has been elected vice-president in charge of European sales of that company. D. C. Keefe, formerly assistant general sales manager, has been appointed to succeed Mr. Albin as general sales manager.

Traffic News

Buffalo-Twin Cities Rate Boost Effective July 1

The Wabash R.R. has given notice that the increase in rate on hard coal from Buffalo to the Twin Cities, amounting to \$1.16 per gross ton, becomes effective July 1. It was expected to go into force May 29, but it was not possible to get out the new tariffs in time. Retailers who specialize in all-rail hard coal have been rushing deliveries through in advance of the new rate, and are going to be pretty well stocked up. The dock concerns state that they do not expect to advance prices in the Twin Cities because of the virtual elimination of all-rail competition.

Obituary

Ray M. O'Connell, 27 years of age, died at his home at Delhi, a suburb of Cincinnati, on May 26. He had been in the coal business all of his business life. Was associated with the Western Coal Company and afterward a partner in the Southeastern Coal Co., resigning a year ago to go into business for himself. Early this year he was stricken with typhoid fever in Cumberland, Md. He had been out only a month when he took the boat ride at the convention of the National Coal Association, where he contracted a cold that turned into pneumonia resulting fatally.

W. L. Davis, attorney, of Lexington, Ky., died at his home there on May 22 after a short illness, of apoplexy. Mr. Davis has long been associated with Colonel Dudley, of the Kentucky River Land Corporation, which owns large acreages in the Hazard district under production of coal. With Colonel Dudley and others he was a large stockholder in operations in Perry and Clay Counties, Kentucky.

Association Activities

The Buffalo Bituminous Coal Association held its annual meeting May 27 and elected Harry F. Coxon, Fred A. Mohr and Gurnsey Camp, trustees, Harold B. Alderman and C. J. Renwick holding over. On the following day the new board, according to rule, selected from its own body the following officers: President, Harold B. Alderman; vice-president, Harry F. Coxon; secretary-treasurer, C. J. Renwick; delegate to the convention of the American Association at White Sulphur Springs, retiring President C. F. Westfall.

The Toronto Wholesale Coal Association held its annual meeting and luncheon recently and elected the following officers: President, Fred A. Fish, of the F. A. Fish Coal Co.; Vice-President, W. H. Cox, of the Cox Coal Co.; Secretary-Treasurer, K. Thompson, of the Dunlop Coal Co. Only routine business was transacted at the meeting.

New Equipment

Another Metal Track Tie

For more than 14 years, many different kinds of metal ties have been placed on the market. S. M. Casterline, of Crafton, Pa., has lately designed a tie which, he claims, overcomes many of the disadvantages of other ties.

In the illustration, cleat A holds one flange of the rail and is riveted to the tie, which is of the usual steel channel construction. Strap B, fastened to the tie by means of a circular collar holds the other flange of the rail. In the strap is a longitudinal slot, so that when it is swung inward to extend over the flange of the rail, the upper end of the stud C projects through the slot. A track spike or any piece of wood or metal may then be forced through the stud, thus jamming the strap down in position and holding it there. It is claimed that one of these ties can be put in position or released in a moment's time with very little effort.

Boltless Mine Tie

Cleat A holds one side of the rail and strap B the other. The end of the strap fits into the slot C and locks the strap in position.

Fan with Heating Unit

A new device has just been placed on the market by the American Blower Company, Detroit, Mich., for heating the air entering warehouses, offices and other buildings. Its light weight and rugged construction make it applicable to installations where ordinary heating units would be cumbersome and impracticable. Steam coils in the heater are made from copper and brass, which offer much less resistance to the heat. The arrangement of the tubes, it is claimed, is such that approximately five times as much heat is transferred to the air as is usual with similar heating devices.

The tubes are made of straight, seamless, copper and brass tubing, upon which is a helically wound copper ribbon forming a continuous fin. This fin is shaped so that a large part of its surface is in contact with the tube. The construction insures easy transmission of heat from the tube to the fin and from there to the air passing over the pipes.

Standard heaters are built to withstand a pressure of fifty pounds of steam, liquid, or any commonly used vacuum. All materials used are of non-corrosive metals insuring long service even under severest conditions. A disk type fan driven by a standard motor is part of the unit and is usually supplied with all orders.

Motor-Driven Air Heating Unit

This heater provides means for controlling the ventilation and temperature of the air in offices or warehouses. A fan circulates the air around steam heating coils designed to warm the incoming air and prevent drafts.

The most efficient way to install the heater is to place it in a steel housing designed to take in cool air near the floor, and discharge it about 7 ft. higher. This insures complete circulation of the air within the range and capacity of the fan.

Transformer for Electric Arc Welding

The American Transformer Co., 178 Emmett St., Newark, N. J., has just developed a new air-cooled welding transformer. The secondary coils are constructed of heavy drawn-copper strips and the terminals are braised to the winding at each turn. This arrangement obviates the necessity of

cast copper terminals clamped to the winding and has made it possible to design the transformer for 750 amps.

The primary circuit consists of two coils so arranged that the transformer may be used on 110-volt or 220-volt circuits. The secondary winding is split into five sections so that from 0.67 to 3.35 volts can be obtained. The transformer is rated for 1 kva. and is for use on 60-cycle circuits. It is particularly suitable for operation on lighting circuits and will no doubt be found very useful wherever high currents are desired.

Relay Indicates Current Flowing in Line

After an accident has happened to a power line or a piece of electrical machinery many have wondered why the protective equipment did not function to prevent the disturbance. Frequently an investigation showed that the protective relays did not function properly, were out of order, or were not even connected in the circuit as was supposed.

To meet such conditions the Westinghouse Electric & Mfg. Co. have recently placed on the market an improved-type induction relay, with an indicating scale which shows the value of the current flowing in the line. This new feature obviates many difficulties, and removes, beyond the question of a doubt, any confusion in a electrician's mind, as to whether or not current is passing through the relay and it is ready to trip a circuit.

There are other advantages of such an indicating relay, it shows the current flowing in a line and directly impresses the electrician or engineer with the difference between the actual current flowing in a line due to poor power factor, and the estimated current which one might think should be flowing. Unbalanced, three-phase circuits are

Instrument Protects Equipment and Discloses Unbalancing

Such a device as this takes much of the guess work out of properly setting overload relays. It immediately indicates any unbalancing of three-phase circuits when used in conjunction with two other similar relays.

very easily detected by this relay. This is especially important on three-phase, grounded-neutral systems. Many three-phase machines and transformers are now working under conditions where they cannot deliver their full or expected kilowatt capacity, because of unbalanced conditions, existing on the lines unknown to the electrician.

New Ball-Bearing Pump

The Ives Manufacturing Co., 203 Hanover St., Baltimore, Md., has recently placed on the market a direct-gear-driven ball-bearing shallow well pump. This unit consists of a single-cylinder, double-acting, brass-lined col-

Small Single-Cylinder Pump

Being brass-lined and having bronze valve seats this unit is quite practical for pumping small quantities of mine water.

Transformer with High-Current Secondary

There are no clamped or soldered connections in the windings of this transformer. Such a detail makes it particularly suitable for alternating-current welding, high-current testing and pipe thawing. Taps can be easily made to the copper lugs.

umn pump made in several sizes. It is compactly designed and accessible for repair. It is driven by an eccentric shaft working at all times in oil. Noiseless operation is obtained by the use of soft-rubber valves fitted on renewable bronze seats. The capacity of the pump is 120 gal. per hr., and it is driven by a 1/4 hp. high-torque motor with automatic pressure control.

Make a Scale in Haste And Repent at Leisure

NO ONE can afford to set a tonnage scale for mechanical loading until its technique has been perfected. If one is made now it will be little lower than that for hand loading. Once fixed no changes in machines or methods will be allowed to modify it, and the art of loading will be arrested in its youth. The operator will be left only with his regrets. The hasty provisions made when mining machines were introduced have hampered development seriously from that time to this. To this day there are only two scales, that for punchers and that for chain machines and the operator has no advantage if he introduces a shortwall or arc-wall machine, provides means for ready loading and unloading of the machine or affords a long working face. In consequence the operator has been slow to adopt the better classes of machinery and advanced methods of operation.

The union is today quite strong. We question whether at this juncture a change in loading machines as revolutionary as that between punchers and chain cutters would cause a revision of the tonnage scale. Consequently it is well to go slowly in forming a scale so that the industry can go rapidly in developing its loading machinery.

Wage Standardization

NON-UNION operations cannot but feel some alarm at the constant wage reductions. They must know that their employees will compare the wages paid in non-union mines with those current in the union regions. If the practice of lowering wages to meet every new contract made continues, the wage rates will fall below a level at which any working man can live. The non-union regions may then be overrun by the union as easily as was the Pittsburgh region in the nineties.

Information has been received that at least one company in West Virginia is paying \$2.88 per day to its underground daymen and \$2.80 to its surface employees. In one Pike County, Kentucky, mine, it is said, drivers are getting 35c. an hour, trackmen 45c. an hour, hand mining is 52c. and machine mining 42c. a ton. Compare these rates with those in the Pittsburgh regions where drivers and trackmen receive 93½c. an hour, where the pick-mining rate is \$1.1164 per ton (thin vein) and \$1.0311 per ton (thick vein) and where the rates for mining by machine and loading by hand are 94c. (thin vein) and 88.31c. (thick vein) in wide work with extra allowances for narrow work.

To all appearances the wage rate in non-union fields tends to decline and will continue to do so unless the non-union operators meet together and decide to stabilize the wage. The present cut-throat competition cannot fail to have an unfavorable reaction on the non-union regions.

You Can't Please Everybody

IT IS sometimes quite difficult to understand the Canadian viewpoint. One man will declare that American coal should be excluded from Canada as she has plenty of her own, another that it is to be regretted that the anthracite operators discriminate against Canada so woefully. As a matter of fact there is no such discrimination, Canada and all remote markets being served first for good and substantial transportation reasons.

Hearing these contrary arguments, one is disposed to believe that Canada argues for herself all the time. As a matter of fact the man who wants to exclude American coal is quite likely to be a coal producer or a Canadian Government engineer, and the man who condemns the slow receipt of anthracite is probably a coal consumer of Ontario. Their point of view is different and so their plans for Canada clash.

What of it! We have advocates in the United States of foreign markets for United States coal and we have those who believe that we ought to ship only manufactured articles, keeping our fuel at home. There are those who believe that the Canadian who has bought our anthracite for years has just as much right to receive it as the consumer in New York. Others contend that we have but little and should keep it for our own consumption and perhaps, in the last analysis, that it is Pennsylvania's coal and it should be kept in Pennsylvania. The miners it will be remembered tried to keep the coal at the mines till the needs of their own communities were fully satisfied.

In England also there are many viewpoints. At one time a tax was put on exported coal to prevent it from leaving the country. But on the whole most people are in favor of the foreign coal trade and of making it easy to get the return cargoes of ships engaged in the transport of coal.

Mr. Geddes shows a little acerbity at times about America's "big stick." Canada has in her time used her "big stick" also. She has trade that some people in the United States want and she can quite readily insist on getting what she wants in return for what we want. She has not been slow to do it. The problem must be settled with equanimity and good will. Our markets should be unrestricted.

If Alberta can displace anthracite coal in Manitoba and Ontario she surely is welcome to do so. Let the best man win. However, it would seem unfair to rest the situation on Sir Henry Thornton and the railroads. Why not for a change try to make the Alberta mines more efficient? Of course there is place for the inefficient operation serving a small local market, but we fear that Alberta has few, if any, mines with the most up-to-date equipment and till she has she must continue to have a relatively narrow market. The vision of Alberta men is on the development of resources. They might well narrow it to developing technique. Properly operated

mines will command their own markets. Economies in operation will do more for Canada than polemics about resources and national heritage.

Fallen in the Pit They Dugged

IN TIMES of coal plethora the operator will do anything to please. He will make all kinds of coal to meet the demands of consumers. As a result he will make sizes he can move only at an immense sacrifice. Once prepared to make that fine size he is likely to continue to make it—first because he has created a demand for it, secondly because he has created a desire on the part of those who have had it excluded from the size they have bought to get coal with the smaller size excluded, thirdly because both parties get to know they can burn that particular coal to advantage and doubt if any other coal would be as economical or desirable in price or quality, fourthly, because much money has been expended in preparing for sizing and the operator does not want to throw it away by ceasing to make the additional size, fifthly, because the consumer buying the finer size will not want to pay more for the mixed size and the consumer buying the larger coal will want to pay less if the coal is mixed. For these reasons, we may cry aloud for simplification of sizes without getting it. Once started it continues forever.

Some sizing is advantageous. Probably, too much mine-run coal is used; it would be better if almost all coal were separated into three or four sizes. Combustion would be better regulated and less coal would be lost on the grates. But the many sizes we now have are a ridiculous excess and serve no useful purpose, except to make marketing difficult. The manufacturer can make sufficient collars or shirts to suit the demand. If there is a shortage of "fifteens" he can put his factory to making that number and cease making "fourteen and a half," but the coal man must continue making all the sizes though perhaps he has sale for only one of them. There is a call for lump and to supply that size perhaps six sizes are made for which there may be little or no market or there is a call for some one of three kinds of screenings with a like result. If coal men could make coal of any size to order without also making sizes that are not desired there would be less harm in this meticulous sizing.

Faults and Mining Fractures

IN DISCUSSING the action of the longwall face a speaker at the Cincinnati Convention questioned whether the fracture below the "point of draw" was vertical or sloping. Knox and Statham have held the British point of view that the crevice was inclined at an angle of about 70 deg. and sloped forward to a point somewhat in the rear of the advancing face, that is over the gob, from which point it sloped back toward the coal face.

The interesting point about the British contention is that the crevice in the roof if thus inclined closely follows the slope of faults, many of which have been traced repeatedly in coal and metal mines. Most of these faults are inclined at 70 deg., and the line drawn from the coal face to the point of draw is about 20 deg. from the vertical or 70 deg. from the horizontal, a striking but perhaps misleading coincidence. No one has ever seen in nature, as far as can be learned, any

turn in a fault corresponding to the angular fracture in the roof of the coal which British theorists describe. Perhaps that is because no one has ever traced faults far enough below the surface. The suggestion, however, that faults are fractures like those in mine roofs is intriguing, and would be more so if the British had been able to make good their contention.

There is no reason why an absolute proof of the British point of view should not be attempted. Suppose a mine is opened in the lowest of several seams and the coal is removed so as to cause a longwall break extending up to the surface. There the locus of the points of draw could be carefully followed on the top of the ground. Openings could then be made in one or more intermediate seams, places being driven till the fracture was reached. The maps of the lowest and intermediate workings and of the surface would show whether the fracture was approximately vertical or sloped down to the coal face or to some line in front of that face. The work done would not be lost, but could be used to advantage in the future development of the seams. Perhaps this interesting experiment yet may be made where conditions favoring this sequence of development would make the operation profitable or at least not unduly costly.

The question is not an unimportant one. On it depends many of our conclusions as to the possibility of working extensive longwall faces without back filling. The problem may appear valueless and a mere abstract question of roof stress and breakage, but it has a distinct economical aspect and is worthy of elucidation.

Consolidation or Bankruptcy

CONSOLIDATION is being considered as a way of avoiding bankruptcy but unfortunately there are many concerns which are not yet convinced that the inventory value is not the true value. The money may have been invested and the investment may have been made in good faith, but the value of the mine is wholly different from the investment. If the coal is not clean and readily salable, if the equipment will not produce cheap coal it is immaterial if \$500,000 or \$1,000,000 has been invested. The headworks have been built for the coal beneath them, and the profit must be derived from that coal and not from the invested capital.

Estimates of value are made only with difficulty. Some will consider only the cost of equipment and unused development; others will base the estimate on possible profit, but that quantity greatly varies. In times of close competition a mine may be valueless; at times of coal shortage the mine may have real value. The true commercial value is hard to obtain. Most consolidations are made on the basis of valuations that do not represent the commercial but rather the inventorial value. Consolidations thus made in many cases have excessive capitalization. In fact a consolidation based on a really conservative estimate of value is hard indeed to establish.

However, consolidation whether with a watered or a true valuation is worth while. The consolidated company is able to keep such mines as it operates working full time. It can work those supplying the cheapest and best coal. It can use experience gained from tabulations in one mine as guides for the operation of another. It can reduce overhead and the cost of selling coal.

McDermid Tipple West of Edmonton

Alberta Seeks to Fill the Coal Bins of Canada

Would Seek Tariff to Keep Out United States Coal but
Would Like to Continue to Sell Coal in Spokane and Ad-
jacent Markets — Too Many Mines Cause High Costs

By M. D. GEDDES
Calgary, Alta., Can.

ALTHOUGH it is not generally known Canada, in coal resources, ranks second among the nations of the world. Unfortunately for her, however, her immense coal reserves are far removed from her present industrial activities and main centers of population.

What a different story there would be to tell today if the North American continent had been discovered by way of the Pacific instead of the Atlantic. Alberta with her coal supremacy would by this time have been a mighty hive of industry and wealth. No nation on earth, during modern times, ever became truly great unless it possessed within its borders an abundance of coal.

As determined by the geological survey of 1913, the total coal reserves of Canada, which includes the Northwest Territories, the Yukon and the Arctic Islands, are placed at 1,234,269,000,000 metric tons, of which Alberta is credited with 1,072,627,000,000, or over 85 per cent.

The figures, as taken from the report just mentioned, are as in Table I.

Quebec and Prince Edward Island, it will be noticed, have no coal so far as is known. The report shows the tremendous preponderance of coal in Western Canada which holds practically all the coal in Canada except what is contained in Nova Scotia. The entire quantity

in New Brunswick and Ontario, as shown by the report, would only last Canada five and a half years, as the present rate of consumption exceeds 32,000,000 tons annually.

The total world reserves are placed at 7,397,553,000,000 tons so it will be seen that out of every seven tons of coal in the world one is in the province of Alberta. To put this another way, Alberta has 15 per cent of the known coal supply of the world, over 70 per cent of all coal known to exist in countries under the Union Jack and fully 85 per cent of all the coal in Canada.

Table II gives the estimated coal tonnage in British possessions, other than Canada.

It has been figured that Alberta alone has sufficient coal to supply a hundred million people for 170 centuries. The coal deposits of that province cover an area

Table I—Probable Coal Resources of Canada

Province	Metric Tons
Alberta	1,072,627,000,000
British Columbia	76,035,000,000
Saskatchewan	59,812,000,000
Nova Scotia	9,719,000,000
Arctic Islands	6,000,000,000
Yukon	4,940,000,000
Northwest Territories	4,800,000,000
Manitoba	160,000,000
New Brunswick	151,000,000
Ontario	25,000,000
Total	1,234,269,000,000

**Table II—Coal Resources of British Possessions
Omitting Canada**

Countries	Tons
Great Britain and Ireland	189,553,000,000
Australia	165,572,000,000
India	79,001,000,000
South Africa	56,200,000,000
New Zealand	3,386,000,000
British Islands in the Pacific	75,000,000
Total	493,767,000,000

exceeding 81,000 square miles and the grades range from lignite to anthracite with the poorer grades greatly predominating in tonnage as is usual in all coal countries. Authorities tell us there are over 45 billion tons of anthracite, semi-anthracite, or high-carbon bituminous coals and this quantity at the present rate of consumption would last over 14 centuries before the low-carbon bituminous or lignite coals would require to be used. Quite a considerable quantity of the lignite coal is of extra high quality and as it is close to present railway lines, is being used extensively.

To an outsider it would seem that Canada could not possibly have any fuel problem, that she is absolutely self-contained on that score at least, yet the irony of the matter is that annually she is paying over a hundred million dollars to a neighboring country to purchase fuel and thus assisting in the commercial prosperity of a foreign land at a crucial time in her own development. The reason obviously is that the major portion of Canada's coal wealth is so far removed from present main centers of population that it does not appear to be economically expedient to use it as a main supply in Ontario and parts of Quebec. Then of course monied interests are well rooted in established mine holdings and allied industries in the present locality where the east gets its main fuel supply and naturally these powerful organizations are doing, and will continue to do, all they possibly can to block "Home fuel for Home fires."

F. W. Gray, coal-marketing expert of the British Empire Steel Corporation, an organization which holds controlling interests in Nova Scotia's coal mines, is quoted as saying: "By the summer of 1950 the larger half of Canada's population will be west of the Great Lakes, and what will take them there will be coal and the industries which must grow up about coal. Ontario's doom as the commercial leader of Canada, has been sounded."

Cutting a Good Seam at Pembina, Alta.

This is one of the better and more up-to-date mines of the province of Alberta. Note the shortwall machine and the electric cap lamps. Only the last word in efficiency can, and indeed ought to, justify an attempt to bring coal all the way to Ontario to compete with coal mined almost on its borders.

Mine at Cardiff, Alberta

The cars at this mine greatly resemble those of central and western Pennsylvania. The coal piled on the top of the cars is blocky and attractive and evidently not piled so as to provide maximum capacity. However, thus loaded there is less waste and less explosive dust on the roadways.

It is well known that the United States is getting a strangle-hold on some of Canada's natural resources, particularly her forests, owing to Ontario's dependence upon her for fuel. In looking at the coal map of the North American continent, it will be noted that the two major coal fields are, south of the Great Lakes commonly called the Pennsylvania field, and on the easterly slope of the Canadian Rockies in Alberta. Canada's main industries have been drawn as by a magnet toward the dominating coal field of Pennsylvania, so today are bunched in the lower peninsula, over 2,200 miles removed from the main coal bins of Canada.

This being the present situation, Ontario from an economic standpoint will naturally remain quite an extensive purchaser of American soft coal, but there is no reason why she should continue to do so in any way that will in the very remotest degree imperil other natural resources of the Dominion. That day has passed. Today Canada can be self-contained, although from an economic standpoint it is not advisable that she should, yet the stage in her development has been reached when no big-stick tactics have any right to intimidate her into negotiating treaties that are detrimental to her general progress. The time has come when Canada should call her soul her own.

Nova Scotians can take care of the coal needs of the Maritime Provinces and Quebec and reach out in portions of Ontario as well. Then in the extreme West, British Columbia can look after her own needs and be prepared at some later date to do a colliery business at least as far south as San Francisco, leaving Alberta with her enormous coal bins to supply the prairies, New Ontario, part of Central Ontario, and in addition steadily pour a stream of coal into Montana, Idaho, Washington and Oregon.

Although quite a large percentage of eastern Canadians claim to favor a reasonable amount of protection, which sometimes is a misnomer through unduly stretching the meaning of the word "reasonable" yet when it comes to putting the same theory in practice, but changing the location so that the westerner might become the beneficiary, the whole principle is considered void and meaningless. How human we are and prone to see merit in that which makes for personal gain with the other fellow footing the bill!

There is no doubt, however, that a large number of those who live in Eastern Canada are beginning to realize the national importance of Canada becoming more self-contained from a fuel standpoint. At the

sixth annual meeting of the United Boards of Trade and Chambers of Commerce of Western Ontario, held recently, a resolution was passed unanimously urging the Dominion and Provincial Governments and Canadian railways and others concerned to endeavor to make it economically possible for Ontario to use Alberta coal.

The main reasons advanced were that thereby it would be possible to avoid a repetition of the unfortunate conditions that have prevailed on several occasions when sufficient coal could not be obtained from the United States, and also that interprovincial trade would be stimulated. As a means of assisting the introduction of Alberta coal into Ontario, over 10,000 tons of domestic coal, as trial shipments, were sent east last fall at specially reduced rates. This coal was, in most cases, well liked, hence the resolution by the western Ontario Boards of Trade, a most representative body of business men in the territory most vitally affected. Another splendid sign of the times is that Premiers Ferguson of Ontario and Greenfield of Alberta, representing the main consuming and producing provinces, are consider-

"Two years ago the U. S. Bureau of Mines unofficially warned the Canadian Department of Mines that within a short time Canada would have to work out her own solution for replacing the anthracite now imported from the United States. No less than three bills were recently before the U. S. Congress to place an embargo on the export of anthracite to Canada. They did not pass, but the fact that they were introduced indicates the drift of public sentiment. This contingency ever hangs above us like a sword of Democles, and the Board considers it of the utmost importance that the use of coals of domestic origin should be more widely extended and that other native fuels should be more fully developed so that the resources of our fuel supply may be widened and diversified."

It is common knowledge that the United States anthracite supply which is found in an area of only 484 square miles, will at the present rate of consumption last only 80 to 100 years. This coal has given excellent satisfaction to Ontario and Quebec consumers, but the time is at hand when of necessity they must make a

Strip Pit at Drumheller, Alta.

An admirable opportunity for big stripping equipment, yet here the men are not even loading into cars but instead are using wheelbarrows, which could hardly be justified even at a local mine for supplying farmers. This mine is northwest of Calgary on the Red Deer River.

ing ways and means of overcoming, or at least greatly lessening, the present difficulty.

Continuing the same line of argument, the Dominion Fuel Board in its Interim Report, 1923, says:

"During the ten-year period from 1912 to 1921, Canada's bill for importing coal exceeded \$580,000,000. In the same period the Canadian coal-mining industry increased its output materially, but the value of the total production from our enormous coal resources was considerably less than the sum of our payments for foreign coal. It is not necessary either to underestimate the natural obstacles in extending the use of native coals, or to set the desirable but doubtful objective of complete fuel independence, in order to warrant a systematic search for practicable methods of permanently re-adjusting a branch of Canadian commerce which has for many years yielded one of the main trade deficits of our national balance sheet and which, with equal constancy, has drawn its increased volume only in minor degree from natural resources within the Dominion.

change and so far as possible that change should be from United States to Canadian coal.

In a small way Alberta is beginning to offset this and is supplying coal to small areas in the adjoining states of Montana, Idaho, and Washington, the chief market at present being the city of Spokane where Alberta coal today can be laid down 75c. per ton below the price of Utah coal. This market consumes about 100,000 tons of Alberta coal annually and is a growing market.

Although Alberta is so remarkably endowed with coal wealth, her average annual output is still under 6,000,000 tons. Table III shows what growth has been made during the past 30 years. It includes, however, a small portion of the southeastern corner of British Columbia, which in this case is included with Alberta shipments as its natural market and railway facilities are identical.

The coal statistics for Canada for the calendar year of 1922 published under the authority of Hon. Thomas A. Low, and prepared by the Mining, Metallurgical and

Table III—Output of Alberta and Part of
British Columbia

Year	Tons
1890	128,753
1900	518,253
1910	4,259,586
1920	7,851,760
The tonnage of the latter year was made up as follows:	
Kinds of Coal	Tons
Steam	4,363,082
Domestic	3,361,105
Anthracite	127,573

Chemical Branch of the Dominion Bureau of Statistics, in dealing with Ontario's fuel problem, says:

"The consumption of coal in central Ontario in 1920 was 13,331,000 tons comprising 10,385,000 tons of bituminous and 2,946,000 tons of anthracite coal, nearly all of which was imported from the United States. A total of 2,259,000 tons of United States coal was dumped at the head of the Lakes in that year. Of this quantity, 296,000 tons was anthracite and the rest bituminous. About 15,000 tons of western Canadian coal were also shipped into the area served by the ports at the head of the lakes.

"In 1921, the total consumption in central Ontario declined to 11,543,000 tons including 2,809,000 tons of anthracite and 8,734,000 tons of bituminous. The ports at the head of the lakes received approximately the same quantity of coal as in the preceding year. The total coal made available for consumption in that area was about 2,249,000 tons, of which 11,900 tons was Canadian coal, 260,890 tons was United States anthracite, and 1,976,000 tons was imported bituminous coal.

"During 1922, owing to the great strike in United States coal fields, the supply of imported coal obtained by central Ontario was considerably reduced and shipments of coal from the Maritime Provinces, particularly New Brunswick, were brought in to help meet the fuel needs of the province. Shipments from Eastern Canada mines amounted to 16,864 tons while Western coal shipped to Ontario points was not brought farther east than the head of the lakes. The total consumption of coal in central Ontario was 9,095,977 tons comprising 1,586,936 tons of anthracite and 7,509,041 tons of bituminous coal. At the head of the lakes, 2,019,794 tons of United States coal was dumped including 57,525 tons of anthracite and 1,962,269 tons of soft coal."

Now let us move westward to Manitoba. Up until about three years ago, that province used Pennsylvania anthracite almost exclusively. At that time, Winnipeg was faced with a fuel problem similar to the situation confronting Ontario today. The citizens of Winnipeg felt no other fuel than the best that could be imported from the far-famed coal fields of Pennsylvania could be expected to prove satisfactory in their rigorous climate. Increased prices, coupled with uncertain delivery, labor and freight difficulties paved the way for Alberta coal and now experience has demonstrated that they can get more heat with less money by using Alberta coal.

The same report on page 75, in dealing with the output and disposition of Alberta coal says:

"Alberta retained in 1922 the premier position among the coal-producing provinces of Canada, a position reached in 1920 when the record output of 6,907,765 tons was produced. The production in 1922 was, however, only slightly in excess of the 1921 output and was also nearly one million tons below the 1920 peak, reaching a total of 5,990,911 tons. Anthracite, bituminous, and lignite coals are all produced within the province."

The following interesting figures are taken from a table in the same report which includes Alberta coal output from 1886 to 1922. In 1886 the output was 43,220 tons. With that as a basis, we will show how often it has doubled. In 1888 it was 115,124 tons; in 1893, 230,070; in 1903, 495,893; in 1906, 1,246,360; in 1910, 2,894,469; in 1918, 5,972,816; and in 1920 the banner year, 6,907,765.

The problem today is, how can Canada's vast storehouse of fuel be used to meet present needs? Alberta is turning out a coal well-suited for eastern domestic use at from \$4.50 to \$5 per ton at the mine mouth. The all-rail haul appears to be prohibitive under present conditions, but so it is with grain. The best solution seems to be rail to the head of the lakes, then water to Toronto.

Canada's coal deposits, and her railways are two of her resources that should, in the common interest of a greater Canada, be interlocked, thus making her more self-contained and less dependent upon the United States. This naturally calls for the lowest possible freight rates which in turn means real co-operation between railway companies, mine owners and government officials. To accomplish this, coal would require to be shipped from mine to treating plant at such times as the railways were slackest and in solid train lots.

By concentrating in this way, as many tons as the physical character of the roadbed will carry, providing locomotives powerful enough to haul the heaviest trains

Lignite Stripping in Saskatchewan

Apparently this is not a machine stripping. Eventually it got too deep for operation in the open and a mine was opened in the depth of the cutting. It would furnish a good opportunity for a big shovel provided the market would be reasonably steady the year round which probably is not the case.

and running them solid from division point to division point, the freight rate should be reduced to the minimum. In addition, the railroads have a lot of rolling stock usually idle for several months of each year and further they have large numbers of box cars that are past the useful stage for hauling grains, yet have years of usefulness for such purposes as coal haulage. These are some of the facts that should induce the railway heads to establish a rate that will permit large consignments of Alberta coal to be marketed in Ontario.

Many feel that under conditions as mentioned, \$6 per ton should be a fair price. The Alberta government freight supervisor wrote Sir Henry Thornton and other Canadian Northern Ry. officials and a quotation from one of his letters reads as follows:

"If we had a \$6 per ton rate in train lots from Coalspur to Toronto, there is no doubt but that Alberta coal could be put down there in competition with American coal and an extensive trade developed which would have the dual effect of keeping Canadian money in Canada and creating work for the unemployed in Alberta.

"The distance from Coalspur to Toronto via Port Arthur is 2,282 miles. A train of fifty 40-ton cars readily could be hauled over this entire route. Fifty 40-ton cars would be 2,000 tons at \$6 per ton which would be \$12,000 per train, \$5.26 per train mile.

"In Canadian Pacific Ry. statement, year ending Dec. 31, 1920, freight train earnings per train mile, lines west, were \$5.82, operating expenses per train mile, lines west, were \$3.58. This of course includes all kinds of trains, but if the average operating cost was \$3.58 per train mile, the actual cost for hauling this 2,000-ton train should be much less and should therefore provide a large margin of profit.

Anyone conversant with coal mining in Alberta knows that the cost of production is abnormally high. How to reduce this is an exceedingly intricate and difficult phase of the situation. In the first place, there are far too many mines in operation for the quantity of coal produced. Increased consumption would assist in cheapening production provided additional mines were not opened up. There are some 380 coal mines of one kind and another in operation in the province of Alberta. Of course, it is easy to open up a mine in many parts of the province as the coal outcrops along river banks and in numerous places farmers and ranchers can back their wagons or sleighs to the seam and

shovel a weathered soft coal right into their vehicles. In a larger way some of the coal companies, after scraping off some six or eight feet of surface soil, use steam shovels to load railway cars with coal. Professor Allen of the Geological department of the University of Alberta has made the statement that the sixteen largest coal mines in the province have sufficient capacity to supply the entire output required at present.

Thus, in a nutshell, is given the main reason for the excessive cost of production, excessive overhead, and yet how to adjust that to a reasonable minimum in a democratic country where everyone is free to acquire coal leases who feels there is a possibility of making a little over a mere living out of the operation, is a puzzle. The records show that mine operators on the whole are not making fortunes. Each year a lot of companies go out of business, but there usually is about a like number ready to take a chance on what seems to them a profitable venture. And thus it is that a long-suffering public pays a high price for fuel in the midst of plenty.

Miners' Wages and the Cost of Coal

Isador Lubin on behalf and in collaboration with the council and staff of the Institute of Economics has published a book on "Miners Wages and the Cost of Coal" which he denominates "an inquiry into the wages system in the bituminous coal industry and its effects on coal costs and coal conservation." It is not a muck-raking treatise but a sober, careful study of coal mining by an unprejudiced outsider. It must be admitted that at times outsiders get erroneous ideas. Mr. Lubin has not always escaped, but when that occurs it is Mr. Lubin's misfortune and not his fault and the facts he has gathered will be useful for those who know the coal industry well but do not have its statistics at their fingers' ends.

Mr. Lubin has gathered some exceedingly useful information. We are justified in regretting that he writes about mining 16- and 18-in. seams. Perhaps they are worked in the United States but it must indeed be rare. Those who know the industry well will be hard put to it to say where these low seams are being worked.

The author believes that the price paid for mining should bear relation to the sacrifice and time expended in producing a ton of coal. That is an excellent assumption but unfortunately neither the company that has expended its money nor the miner that has established his home has ever been known to pay much attention to it. The operators and mine workers establish a scale which Mr. Lubin says is for certain mines inequitable and which possibly is as inequitable as he declares it. Nothing compels the miner to accept it. He can move to some other district but he does not. Prices in the city vary from store to store but some go to one store and some to another.

Something besides financial advantage rules. John T. Ryan remarked about the varying wage scales in France. Others have spoken about it in England. Mr. Lubin has found it in the United States. It is found everywhere. It appears, nay it is, unreasonable, but the United Mine Workers of America will never change it. The union is not ready to depopulate any district, to close down any mine. The economics of the industry does both, but it would not do for the labor union to be as inexorable as economics. So the inequality con-

tinues and will continue and men will keep on making scales that assure them of their jobs be they good or bad. A job almost always appeals to a man and the closing of a mine or a factory brings its heartbreaks.

But this is beside the issue. It is not the part of the conscientious critic to quarrel with 0.5 per cent of a book when he approves 99.5 per cent, though that is just what he usually does. In 316 pages 5x8 in. Mr. Lubin has packed an astonishing quantity of information. The book is published by the McGraw-Hill Book Co., 370 Seventh Ave., New York City. A. M. Ogle read the first nine chapters. One wonders he allowed the author to say, as he does on page 14, that a "horizontal tunnel" is "sometimes called a drift or *slope*."

Much Heat Wasted in Furnace Walls

An insulated wall loses only about 40 per cent as much heat as an uninsulated wall and the savings through insulation aggregate approximately 480,000 lb. of coal per year for 1,000 sq.ft. of wall surface. At \$5 a ton for coal delivered, this would represent a loss of \$1,200 actually saved by insulation of the walls. Data for various insulators and refractories show that a layer 0.5 in. to 1.5 in. thick of the various insulators has an insulating value equivalent approximately to 9 in. of fire or silica brick.

The thermal conductivity of insulators varies with the temperature at which they are used, their density, the unevenness of the distribution of the pore spaces, the temperature to which the material has been subjected during manufacture and possibly with the elasticity.

The need for insulation increases without an increase in the temperature of the furnace. These facts were presented by Roberth Calvert, Lompoc, Cal., at the Heat Transfer Symposium of the Division of Industrial and Engineering Chemistry in connection with the meeting of the American Chemical Society at Washington. The heat losses by the industries of the United States, said Mr. Calvert, are equivalent to fuel costing approximately a billion dollars yearly. Part of the loss is carbon in the ash, part is heat that goes up with the draft and part is heat passing through the walls.

How Wire Rope Is Manufactured and Used and How Its Life May Be Prolonged in Mine Service

Physical and Chemical Tests Constantly Check Wire-Drawing Process — Saturated Core Acts As Cushion and Lubricant — Care of Ropes and Their Application to Mine-Hoist Problems

BY LAWRENCE W. BEVAN

WIRE rope was made some time prior to the destruction of Pompeii, which occurred in 79 A.D. for we find exhibited in the Musio Borbonico in Naples a short length of 1-in. diameter bronze wire rope which was excavated from the ruins of Pompeii. Beyond the fact that it was made of wires twisted into strand and the strand into rope we have no further information. Subsequent to this date there is no record of the existence of stranded rope until early in the nineteenth century.

However history records that prior to the year 1351 single wire was hammered to shape by smiths, but since that date it has been drawn by power. It may be worthy of note that the first wires were those of precious metals.

The application of wires to make rope is first mentioned in the construction of a suspension bridge in Geneva, Switzerland, in 1813. Such ropes as these, however, would not strictly be classed as wire rope today, for they were made by laying a number of charcoal-iron wires parallel to each other and binding them together by a serving of smaller iron wires which in turn were covered with yarn. In 1835 a cable of this type was made for the Freiburg Suspension Bridge in Germany with a span of 800 ft. in the clear. The supporting cables were composed of twenty bundles of wires of $\frac{1}{8}$ in. diameter laid parallel, the total diameter being $5\frac{1}{2}$ in.

Cables manufactured according to this principle, known as the Selvagee construction, have been applied in this country on the Niagara Suspension Bridge, Ohio River Bridge, Brooklyn, Manhattan and Williamsburg bridges in New York City. It is interesting to note that this same type cable will be used for the world's largest suspension bridge, with a span of 1,750 ft., which is now being constructed between Philadelphia and Camden. The main supporting cables will be of 30 in. diameter, and will contain 16,531 galvanized steel wires of $\frac{1}{8}$ in. diameter. The wires for these main cables if placed end to end would completely encircle the globe at the equator.

FIRST STRANDED WIRE ROPE USED AT MINE

The first so-called stranded wire rope was made in Germany in 1834 by a mining engineer by the name of Albert, who used a rope which was composed of iron wires, for hoisting ore in the shafts of the Hartz mines. This rope, fabricated with much difficulty, demonstrated its superiority over its hempen predecessor. In 1837 Albert, before the Engineering Society of Berlin, read a paper on the "Construction and Manufacture of Stranded Wire Ropes" in which he mentioned that ropes made of 4, 6 or 8 strands of four wires of 0.144 in. diameter were used.

In England in 1840 R. S. Newell was granted the first patent papers for "Improvements in the Manufacture of Wire Rope, and Machinery for Carrying Same into Effect." In these papers we find the first mention of the use of a central heart or core in the making of wire rope.

NOTE—Paper read at Anthracite Session of American Institute of Electrical Engineers. Head piece shows a small rope haulage system at the coal face. Such systems have largely supplemented mine locomotives.

In the year 1812 a partnership was formed by Erskine Hazard, father of Fisher Hazard, the founder of the Hazard Manufacturing Co. and Josiah White for the purpose of operating a mill on the banks of the Schuylkill near Philadelphia for the manufacture of wire and nails. These men built a bridge of wire over the river for the use of their workmen, and thus demonstrated its practicability for this purpose. To the best of my knowledge this was the first wire suspension bridge in America.

At this time no well-constructed machinery was in use for the manufacture of wire, so these two men exerted their inventive genius to produce equipment for the purpose. In the early '40's Erskine Hazard invented and made the first wire-rope machinery in this country.

The first wire was made, of course, of wrought or charcoal iron, and it is worthy to note that the first successful attempt to use anthracite in the iron industry was by these two men in their wire mill. Historians

materials used in wire rope are divided into seven classes, iron, low-carbon steel, traction steel, cast steel, medium plow steel, plow steel and olympic steel. These materials vary in breaking strength from approximately 65,000 to 280,000 lb. per square inch. As purchased they must meet rigid specifications in order to insure the high quality demanded by the various users. All iron and steels as received are carefully inspected and before being drawn into wire they are thoroughly tested in physical testing machines and a complete chemical analysis made. In fact all materials entering into any process of wire drawing or wire-rope making are thoroughly tested and analyzed before use.

Iron and steel are received by the wire mill in coils of rods varying in diameter from No. 0 to No. 5 gage, i.e., from 0.34 in. to 0.22 in. diameter. These rods are as a rule covered with rolling-mill scale which is removed by pickling in sulphuric-acid baths until the scale is entirely dissolved. The rods are then given a lime

Fig. 1—Fast Frequent Hoisting

High headframes usually increase the distance between the sheaves and hoist drums and greatly lengthen the life of the rope. Such hoists as these are less severe on ropes because the rope is generally wound in single layers. Reverse bends and sudden shocks soon break the small strand wires.

write that "Cist, Miner and Robinson succeeded in sending two arks of anthracite to Philadelphia, via the Lehigh and Delaware Rivers. The cargo was bought by White and Hazard at \$21 per ton. The mill hands while experimenting with the new fuel kept stirring the coal, but it refused to burn. Finally, being disheartened, they threw a quantity of anthracite into the furnace, closed the door and quit work. A workman returning for a coat some time later found the furnace red hot. Hurriedly he summoned other workmen, and they succeeded in running off three separate heats of iron."

At a later date, with the introduction of the Bessemer process, and later the Siemens-Martin or open-hearth process, iron wire was replaced to a large extent by steel. It is apparent that with this change of material it was necessary to make changes in all processes incident to wire drawing.

It is only within recent years that English steels have been replaced by steel of American manufacture. The

bath to neutralize the acid. After this they are heated in bakers or ovens to drive off acid or hydrogen.

When cool, the rods are taken to the wire-drawing mill where without preheating the rod is passed through a steel die, and reduced in diameter. The rod is then taken to the annealing furnace or the patenting furnace and heated to relieve the effects of wire drawing and permit the rod to be further reduced in diameter. This heating leaves a certain quantity of scale which is then cleaned off in an acid bath as before. The rod is then lime coated, baked and taken to the wire drawer for further drawing. Cast steel, which is the material used in the majority of operations in the anthracite region, has a tensile strength 50 to 55 tons per square inch when the wire drawer receives it for the final drawing.

This rod is reduced in area approximately 75 per cent in a series of 5, 6 or 7 passes through the wire-drawing die and will finish not more than 0.001 in. from the required size, and have a tensile strength of 80 to 85 tons per square inch. It is well to remember

Fig. 2—Drawing Wire

These are the wire drawing benches where the steel is reduced in size before being twisted into rope. The tensile strength of the material is high and much power is required to pull the wire through the dies.

that the physical and chemical laboratories are constantly checking the material as it passes through each process. It may seem that the process just described is excessively long, but it is merely a good example of the usual procedure necessary for making the wire which goes into the manufacture of 1½ in. diameter rope. For rope of smaller diameter, say of ¾ in. diameter in which 0.019 in. diameter wire is used there is much more processing. For wire rope the wire sizes range from 0.009 in. in diameter to any larger size desired.

ROPE-CLOSING MACHINE COMPLETES PRODUCT

After the wire is drawn to the desired size it is spooled on bobbins and placed in a stranding machine, which twists 7, 19, 37 or any number of wires into a strand. The strand as it leaves the nozzle of the machine passes through a die and then on to a larger bobbin or spool which in turn is placed into a larger unit called a rope-closing machine. This device operates in the same way as a stranding machine, twisting the 6 or 8 strands into a rope. Through the center of the shaft of this machine a core of manila, heavily saturated with a good lubricant, passes and the strands are twisted around it. This core acts as a cushion and holds the grease or lubricant in reserve. This does not however, obviate the necessity of the subsequent

use of a lubricant when the rope is placed in operation.

It was previously mentioned that wire rope was primarily designed for mining operations, and it is therefore still used in enormous quantities in the anthracite and bituminous coal regions for hoisting coal, water and men, outside and inside the mines. A notable operation, which depends to a great extent on wire rope, is the Ashley Planes near Wilkes-Barre, Pa.

This hoisting incline consists of three planes with a total elevation of 1,025 ft. in about 3 miles, on which is hoisted 10,000,000 tons per year. The largest main cable on the middle plane, weighs 12 lb. per foot and is of 2¾ in. diameter. The main cables on the other two planes are of 2½ in. diameter. The three back cables or tail ropes are of 1½ in. diameter. The total weight of the wire rope used is 190,000 lb.

The question, "When has a wire rope reached the end of its usefulness, and when should it be removed?" has been much discussed. As the result of a study of this subject made by the Bureau of Standards the investigators stated in substance that a rope should be removed after a certain number of broken wires appear in each of the strands.

Tables have been prepared supporting this conclusion, but undoubtedly certain definite loads, speeds, head-sheaves, drum diameters and shafts of varying depth were used to arrive at the results. The report

Fig. 3—Rope-Closing Machine

Most steel ropes are now made with a core of manila. This material is saturated with a good lubricant and assists the external lubricant which should be applied occasionally after the rope has been placed in service.

is no doubt a useful guide, provided it can be applied where conditions are the same, or nearly like those from which these tables and figures were compiled.

However, each operation varies, in some cases considerably, sheave and drum diameters are not standard; therefore, it is quite necessary that for each operation a separate study be made to determine exactly the factor of safety so that with any number of broken wires or with a reduction in cross-section due to wear the remaining breaking strain of the rope may be known. It is obvious that, due to difference in mining conditions and operations, no set rule for the removal of the rope can be set down to govern each case.

In the catalog of wire-rope manufacturers, tables appear showing "Proper Working Loads" of wire rope of given sizes and grades. This proper working load in most cases is $\frac{1}{5}$ of the approximate breaking strength, or in other words, the factor of safety is 5. The proper working load must not be interpreted to mean tons of material which can be lifted, but the load should be figured to include the material, the carriage, the rope itself, the bending stresses, the stress due to starting, etc. Bending stresses should receive careful consideration from the engineer. In the anthracite mining field sheaves and drums of ample size have been employed in 90 per cent of the operations, so that the stress due to bending has been reduced to a minimum.

DANGEROUS STRESSES OCCUR IN REVERSE BENDS

Reverse bending, such as occurs with an underwind rope brings severe stresses on the steel causing an early deterioration by reason of a definite set given the rope, as it comes off the head sheave. The permanence of the set depends on the relation of rope diameter to sheave diameter. The smaller the sheave the greater the set. Obviously the set is not altogether overcome when the rope starts to wind on the drum in an opposite direction to the way it comes off the head sheave, hence the effect of the latter bend is more severe. Individual wires removed from ropes which had operated under conditions of reverse bending show under the microscope minute cracks, sometimes running in planes between the grains. In other cases the grains themselves are cracked. On mine hoists the distance between the head sheave and hoist drums is such as to favor the rope, but in some installations the bend is reversed in a few inches, thus causing a much earlier breakage of the iron or steel wires.

Wire rope may often fail due to repeated shocks being thrown on the rope, not one of which in itself would be sufficient to cause fracture. Suddenly applied loads approaching the elastic limit, even though at intervals days apart, eventually tire out the rope so that at some time or other when a heavy load, which ordinarily would not cause fracture, is suddenly applied the rope will break. The man in charge will be most positive that the load was much less than the rope should lift. The effect of these strains or over-strains can best be shown by microscopic examination of the metal.

The overlapping of the rope on the hoisting drums with the occasional slipping down of the top layer into grooves made by the lower layer will have two bad effects. First, it will cause jerks which increase the load on the rope by a quantity depending upon the slack between the drum and head sheave. In most cases this is small, but in time the wires will show the effect of these shocks not only because of the in-

creased load but also because a vibration is set up in the rope which usually settles at one point causing trouble later. Second, the inner wires will crush somewhat from the squeezing between the top and bottom layer and will assume a pear or bell shape. In this disturbed condition it is impossible for these inner wires to perform their proper function, and the outer wires will be forced to take more than their share of the load, also they will tend to take the form of the inner bell-shaped cushion thus causing abrasion on themselves. Overlapping, cannot in all cases be eliminated, and therefore the need for frequent rope inspection is essential.

All users of wire ropes appreciate the value of protecting them from mine or other injurious water, which corrodes the steel, but it might be well to state that as the sulphur water acts on the steel, hydrogen is

Fig. 4—Nothing Can Take the Place of Rope Here

The hoisting shaft is the neck of the bottle and much depends upon the steel cable. Here, as in other service, it is important to lubricate the rope properly. Accidents due to rope failure are extremely rare; occasionally, when an accident occurs and the headframe is wrecked, the rope is not broken.

liberated which replaces the iron in the steel, acting as a metal itself and remaining occluded. Heat of the correct temperature applied a definite length of time will drive off the hydrogen, but in the case of a wire rope in operation this is impractical, therefore it is imperative that the rope be protected by the use of some mineral compound which will resist the action of the acid and so prolong the life of the rope.

Where wire rope plays an important part in an industry, it is most essential that an inspector who is familiar with the construction and application of wire rope be employed. The duties of an inspector are too numerous to mention, but the mere fact that most mining companies recognize this need and have in their employ such a man, emphasizes the point that wire rope is a part of the equipment which requires expert knowledge, careful handling and the most rigid inspection.

What Kind of Rock Dust Should Be Used in Mines?

Fifty per Cent Should Pass Through a 200-Mesh Screen—A Smaller Percentage May Be Thus Fine Under Certain Conditions—Some Mines Need Seventy-Five per Cent of Non-Combustible—Effect of Methane

BY GEORGE S. RICE, J. W. PAUL AND R. R. SAYERS*

STANDARD rock dust for use in the rock dusting of coal mines might be defined tentatively as powdered mineral, light colored and free of carbonaceous matter and free silica, all of which will pass a 20-mesh screen while 50 per cent of it will pass through a 200-mesh screen.

Such dust may be prepared from limestone, gypsum, anhydrite or shale free of sand and flint. For the initial rock dusting of the average non-gaseous bituminous-coal mines enough standard rock dust should be applied so that the combustible content of the resulting mixture of rock dust with mine dust shall not exceed 45 per cent, a range somewhere between 35 and 45 per cent being the practical objective sought.

All entries, slopes or passageways and room necks should be rock dusted. Additional safeguards are: (a) Rock dusting rooms; (b) scattering of dust in vicinity of shots before firing; (c) placing of barriers in the mouths of panels, cross-entries and other key positions.

Redusting becomes necessary whenever the combustible content of the mine dust exceeds the permissible maximum. This should be determined by regular, systematic sampling, followed by a simple analysis of the samples for combustible content. A Bureau of Mines volumeter for measuring the density can be used for the determination of combustible content.

In gaseous mines from 5 to 10 per cent additional non-combustible is required for each per cent of methane present in the air current.

Specifications for size and character of rock dust to be used in coal mines as a means of preventing disastrous explosions have not yet been standardized by the Bureau of Mines, but so many inquiries have been received from mining operators and engineers who are considering adopting rock dusting for their mines that this memorandum has been prepared.

(1) *Size of Dust Particles.*—The finer the size of particles of rock dust, the more easily is the dust raised in the air with the coal dust to prevent the propagation of flame, if enough rock dust is used proportional to the kind of coal dust found in any given mine.

Only such particles of either coal or inert material as will pass through a 20-mesh sieve are considered to be dust. Thus dust—whether coal dust or rock dust—would include particles ranging from 20-mesh (roughly about $\frac{1}{30}$ in. diameter) to the finest microscopic size. However, mine road dust that passes through a 20-mesh sieve will vary widely in its proportion of the finest dust and correspondingly in its explosibility. From experience in tests at the Experimental Mine, the Bureau of Mines has adopted that percentage of dust by weight that passes through a 200-mesh sieve for the criterion of the most explosive size of any coal dust,

also of the most effective size of inert dust to limit an explosion.

Also, the Bureau's experience is that rock dust should be ground until 50 per cent will pass through a 200-mesh sieve, but a dust having a smaller percentage through 200-mesh may be used provided: (a) That at least 30 per cent passes through 200-mesh, and (b) that a proportionately larger quantity of the dust is used. For example, if the unit of weight of the finer dust required be represented by 1, the quantity of dust having 30 per cent through 200-mesh would be determined by the proportion:

$$30 : 1 :: 50 : x \text{ (} x \text{ being the quantity required of a dust of which 30 per cent will pass through a 200-mesh screen)}$$

$$30x = 50$$

$$x = 50 \div 30 = 1.7 \text{ or } 1.7 \text{ times as much should be used as of a dust of which 50 per cent will pass through a 200-mesh screen.}$$

These specifications are similar to those of the British standards of size as defined in their regulations, except in giving a slightly coarser dust. The British maximum size is 28-mesh, and although the criterion of the finest size is that passing through their standard 200-mesh sieve, this size corresponds to the size through the usual American standard screen of 250-mesh.

(2) *Character of Rock Dust.*—(a) As concerns composition and physical properties of the rock dust, less than 2 per cent combustible material is desirable, and it should not be as much as 10 per cent. If the inert dust contains any combustible material, 1 per cent increase in the quantity of dust should be used for each per cent of combustible material.

(b) Rock dust should be as light in color as possible, both to permit ready observation of freshly distributed coal dust from the regular coal production operations of the mine and to increase the illumination of the passageways which tends to prevent accidents arising from poor illumination.

(c) Rock dust should not contain an appreciable quantity of siliceous particles, and dust from sandstone and dust from sandy shale should not be used. Dust from pure limestone, dolomite, gypsum and anhydrite are preferable. The dust from roof shale free from gritty material is extensively used in Great Britain, but not all roof shales are suitable; often they are too sandy or contain too much combustible matter. The Bureau of Mines is prepared to advise operators as to the suitability of the material or rock that they propose to pulverize for coal mine dusting. Such advice may be obtained by submitting a sample of the material to the Bureau of Mines Experiment Station at Pittsburgh, Pa., where chemical, petrographic and physiological tests will be made.

(3) The quantity of rock dust that must be used for

*Chief Mining Engineer, Coal Mining Engineer and Chief Surgeon, Bureau of Mines, respectively. Dr. Sayers is also Surgeon, U. S. Public Health Service.

NOTE—The British and French methods of rock dusting are described in Bureau of Mines Bulletin 225.

initial dusting for any particular stretch of passageway depends upon: (a) The character of the coal, whether high volatile or low volatile; (b) the size of the particles of coal dust found on the road, ribs and timbers as determined under specifications (1); (c) the percentage of inert matter naturally present, that is, moisture and ash of the coal and ash of dust from the roof, partings and floor that has become mixed with the coal dust; (d) the quantity of road and rib dust in the specified stretch of passageway before rock dusting.

General information on factors (a) and (b) can be obtained by studying results of tests of various coals in Bureau of Mines, Bulletin 167, or by applying directly to the bureau.

Factors (c) and (d) can be determined only by systematically sampling the dust in that part of the mine to be rock-dusted in such a way that the quantity per linear foot of passageway can be estimated approximately. Practically, however, the way to start is to clean up a stretch of passageway and rock dust it, then from time to time sample the resulting mixture analyzing the sample thus taken.

(4) *Redusting*.—After the initial rock dusting, samples should be taken at regular intervals to ascertain how rapidly coal dust is accumulating, and from the analysis to determine whether or not additional rock dusting should be done and whether cleaning up is necessary before redusting.

FACTORS INFLUENCING RAPIDITY OF DEPOSITION

The rapidity with which coal dust is made in any mine varies with the friability of the coal, the method of mining, and, most important of all, on the spillage of coal in transportation whether by the coal escaping from leaky cars or by material in the "topping" being jarred onto the roadway. These factors taken with the character of the coal dust and the quantity of natural rock dusting make the quantity needed for the continued dusting of a particular mine or district of a mine difficult to estimate without some trial. Some parts of an entry must be dusted every week; in other parts of a mine redusting will last for several months. In British mines the quantity of rock dust used daily in any one mine varies according to the conditions and size of the mine from 5 in the smaller to 20 tons in the largest mines.

(5) *Maximum Permissible Percentage of Combustible in Road Dust After Rock Dusting*.—It is not possible, as indicated above, to state the maximum permissible percentage of combustible content in road dust applicable to all mines. The amount depends on many factors and ranges from 75 per cent for semi-anthracite to only 25 per cent for certain pulverized high-volatile dusts.

Conversely the minimum percentage of non-combustible content that will prevent explosion propagation varies from about 25 per cent for the least explosive to 75 per cent for the most explosive. If firedamp is present in any part of the mine, a greater percentage of rock dust must be used than in a mine practically free from gas. Therefore, it is not possible to lay down a hard and fast rule that will apply to all the different conditions and characters of coal dusts found in the mines of the United States.

The British law says the dust on floor, roof and sides throughout shall always consist of a mixture containing not more than 50 per cent combustible matter. In other

words, there must be 50 per cent of incombustible matter.

Tests in the Experimental Mine of coal dust from various mines of the United States indicate that although 50 per cent of incombustible material (total ash plus moisture) will prevent ignition of many natural mine-dust mixtures, with no firedamp present, it will not suffice if firedamp is present, and it will not prevent propagation of an explosion when strongly started, as by gas and coal dust at the face. To meet such contingency from 55 to 65 per cent incombustible matter is required to prevent propagation, and if 1 or 2 per cent of firedamp is present in the air current, 5 to 10 per cent additional incombustible must be used.

It must be remembered, however, that the British regulation sets a *maximum* of combustible matter in any part of a mine, and to meet this regulation it is found that the average combustible in the treated road dust of British mines will range from 40 to less than 30 per cent combustible, or conversely have 60 to over 70 per cent non-combustible.

ROAD DUSTS CONTAIN MUCH INCOMBUSTIBLE

Further, it must be remembered that the average natural road dusts in American mines, as determined by thousands of samples, contains usually over 20 per cent non-combustible (ash plus moisture) and sometimes 30 to 50 per cent, so that an additional quantity of rock dust equal to the quantity of coal dust present in a passageway (after it has been well cleaned up) may be sufficient ordinarily and sometimes a small quantity may suffice.

Subsequently, the quantity required to keep the roadways safe will depend on the control by the mine management of the production of coal dust. Rib and timber dust is much finer than road dust and contains less incombustible matter, consequently it requires a larger proportion of rock dust to make it safe against the propagation of an explosion; moreover, it is in a position from which it is easily brought into suspension as a dust cloud. In rock dusting effort should be made to supplant the coal dust on timbers and rib projections, then the coal dust which is subsequently made and carried by air currents till it falls on these places will tend to roll off, as the angle of repose of coal dust is less steep than that of rock dust.

(6) *Sampling*.—One of the greatest advantages of the method of rock dusting is that the danger or freedom from danger of explosion propagation through the agency of mine dust can be determined by sampling that part of the mine under suspicion and analyzing the samples. This more or less positive ability to determine the degree of safety during a period of some days or weeks is invaluable to the mine operator and the state inspector, as systematic records of the condition of any part of a mine can be made.

The method of sampling in a roadway requires further development. The Bureau of Mines has heretofore been using a special sampling scoop with screen and brush and has taken a sample of the dust about 8 in. in width across the roadway, on ribs and overhead timbers. All coal passing over a 10-mesh sieve is rejected in the mines. Before analysis the sample is dried, if necessary, and is then screened in the laboratory through a 20-mesh screen and the oversize rejected. This gives a fair sample of the dust at any one cross-section of the passageway. Investigations are now

being conducted to develop for such sampling a portable vacuum-cleaner device not requiring electricity for its operation.

To a certain degree such small samples are grab samples, but if they are taken at regular intervals along the passageway, they give a fairly accurate average for the distance examined. An official test of this was made at the Bentley Colliery, Yorkshire, England, in which a comparison was made of an average of the analyses of many small samples in a given stretch of entry with the analysis of a gross sample obtained from shoveling and sweeping up the entire dust in that same length of roadway. The ash content by the two methods agreed within a few per cent, so the many small samples were regarded as fairly representative of the dust in the passageway.

(7) *Analysis of Road-Dust Samples.*—A comparatively simple fire analysis will determine the total combustible of a mine dust except when limestone is used or other dust that loses carbon dioxide or water of composition. For such dusts these losses must be determined and added to the non-combustible material.

The Taffanel volumeter, modified by Fieldner, of the Bureau of Mines, is a device for quick determination of the combustible content. It is based on density of the non-combustible material. Tests have indicated that it is accurate within a few per cent.

(8) *Extent of Rock-Dusting Necessary in a Mine.*—Questions are repeatedly asked such as: How extensive is it necessary to carry rock dusting through the mine to prevent an explosion? Is it necessary to rock dust rooms? Is it necessary to rock dust entries? In the opinion of the Bureau engineers, it is necessary to rock dust all passageways that contain any coal dust

whatever. It is not enough simply to rock dust the rooms. Many of our most disastrous explosions have started in entry ways and even near the mouth of the mine, through ignition of coal dust by electric shorts from trolley wires or power lines or by explosions of bodies of gas forced into the entry from adjacent workings.

There is always the possibility of ignition of fire-damp from one cause or another. Therefore, it does not suffice to prevent *ignition* of coal dust in a particular locality; the dust must be so generally neutralized that it will prevent *propagation* of an explosion of a body of firedamp or of locally untreated or insufficiently treated coal dust.

The first step should always be to rock dust the haulage roads and dusting should be carried on into the cross entries, subsidiary entries and air courses. The next step is to rock dust the room necks and then gradually extend the rock dusting up into the rooms. Rock dust close to the face, although desirable is not so vital as thoroughly dusting in the entries, because an explosion starting in a room will die away on well rock-dusted entries.

(9) *Rock-Dust Barriers.*—The Bureau of Mines engineers believe that an additional measure of safety is to install rock-dust barriers at the mouths of all panels, cross-entries and other key positions, but the barriers should fulfill the specification suggested by the Bureau in Technical Paper 84 to insure operation. Barriers should not be regarded as sufficient in themselves or as the most important feature. General rock dusting is much more important; the barriers should be considered only as secondary defenses.

Deep Betteshanger Mine in Kent Shows Present-Day British Practice

AT A NEW MINE, the Betteshanger Colliery, now under construction by Pearson & Dorman Long, Ltd., in east Kent in the South of England, there are twelve seams; one 2 ft. 6 in. thick at 1,208 ft.; one 2 ft. thick at 1,504 ft.; one 4 ft. 5 in. thick at 1,813 ft.; one 2 ft. 10 in. thick at 1,926 ft.; one 5 ft. thick at 1,975 ft.; one 3 ft. 6 in. thick at 2,310 ft.; one 4 ft. 1 in. thick at 2,364 ft.; one 3 ft. thick at 2,403 ft.; one 2 ft. 7 in. thick at 2,513 ft.; one 4 ft. 6 in. thick at 2,562 ft.; one 2 ft. 3 in. thick at 2,592 ft.; one 7 ft. 9 in. thick at 2,632 ft. These seams divide themselves in two series each of six beds with an aggregate thickness in all of 44 ft. 5 in., the average thickness being 3 ft. 8 in.

The coals have a decreasing percentage of volatile hydrocarbons with depth. The six upper seams range in volatile matter from 28.66 to 18.47 per cent and the six lower seams from 16.85 to 14.03 per cent. One of the best analyses, says the *Iron and Coal Trade Review*, is that of the 4 ft. 6 in. seam at 2,562 ft. This is as follows. Volatile matter, 14.03 per cent; fixed carbon, 80.03 per cent; ash, 4.97 per cent; sulphur, 0.97 per cent; calorific power, 14,414 B.t.u., an extremely low-volatile bituminous coal.

The company has mineral rights covering nearly 60 sq. miles, but to Betteshanger colliery is apportioned 4,700 acres. A boring on the site of the shaft shows that at a depth of 875 ft. the greensand will be encountered with water at a pressure of 295 lb. At a depth of 960 ft. water will be found at a pressure of 112 lb. The coal measures will be reached at 975 ft.

From the experience gained in other parts of the field 2,000 gal. of water will flow into the shaft per min. In the upper chalk formations the water will be excluded by the cementation process, below that the water will be closed off by tubbing. The shafts will be sunk to a depth of 2,598 ft. starting operations, however, on a seam 3 ft. 10 in. thick at a higher level. The annual output is expected to be 840,000 short tons per annum.

The headframe is of twin-channel construction and 80 ft. high. It weighs 100 tons and has sheaves of 20 ft. diameter. The permanent plant will be used for sinking. The hoisting engine will have a pair of 36-in. cylinders with a stroke of 84 in. and a cylindro-conical drum increasing from 16 to 28 ft. The maximum speed in the shaft will be 72 ft. per sec. or 49.09 miles per hour, a complete wind taking 58 sec. During the sinking operation a parallel drum is to be employed.

It will be noted with interest that the shafts will be circular and 22 ft. in diameter in the clear. They will be lined with concrete, the pit bottom being so arranged that the whole output, or any part of it, can be hoisted through either shaft. The cages will be double decked with four cars on each deck. The capacity of the cars will be only 1,680 lb., a clear evidence that the British mines even where new and deep are not being provided with large rolling stock from the American point of view. The boilers will be up to the best standards, being of Stirling type with economizers and superheaters. They are designed for a working pressure of 200 lb. with a superheat of 200 deg. F. They will have chain-grate stokers and both forced and induced draft, the fans for that purpose being electrically and steam driven.

New Methods of Operation Reduce Production Cost

More Details Regarding "V" System of Mining with Conveyors —
O'Toole Machine Cuts and Loads 7,000 Tons in a Single Month — Little
Shooting Required — European Longwall Problem Not Like Ours

How Conveyors Have Lowered Cost of Mining

A COMPANY, having coal with a roof that will stand up without support over a span of 30 or 40 ft. expects to put in conveyors and to cut and shoot the coal face two or three times a day, said J. W. Bischoff, general manager, West Virginia Coal & Coke Co., Elkins, W. Va. at the Cincinnati Conference. Mr. Bischoff said that the longwall system or any long face had its advantages where conditions favored its use. It gives the advantage of close supervision and concentration of work with consequent reduction in the cost of haulage, ventilation and drainage.

Mr. Bischoff made his remarks in the absence of J. Dearing Christian, assistant to the president, Imperial Colliery Co., Burnwell, W. Va., and Everett E. Drennan, president, West Virginia Coal & Coke Co., Elkins, W. Va. He was somewhat hampered in making his remarks because as he stated "I don't suppose there is a man in this gathering that has not read the descriptions of our system of mining in *Coal Age*." His statements were therefore merely supplementary.

LARGE TONNAGES HANDLED

He explained that the coal at the mine operated by conveyors and the "V system" was 6 ft. thick, the bottom coal being 15 or 16 in. thick and the shale parting above it 4 in. to 9 in. thick. A machine is now being constructed for loading. This should be ready about the middle of this month. He said that no machine now on the market could be worked to advantage with the conveyor. All the coal loaded at the mine is conveyor-loaded, there being two installations each carrying 700 to 800 tons per day.

Mr. Bischoff said that the conveyors were kept running continuously, cars being kept at the head of each main conveyor at all times. The haulage locomotive can make a trip to the outside and back again in the time taken to load a trip of cars. These cars are never uncoupled. When the coal was loaded by hand each car carried 3 tons; with conveyor loading the capacity has been reduced to 2½ tons.

The cost of operation for all expenses except investment charges has been reduced 30 to 35 per cent. Before the change from hand to conveyor loading the output per man employed in and around the mine was 5½ to 6 tons; now it runs from 10 to 11 tons. The lower tonnage with hand loading was not due, Mr. Bischoff said, to any inefficiency on the part of the men, as they were all good loaders. The whole credit for the

increase in tonnage per man must be given to the new system.

Mr. Bischoff said also that even with irregular operation there would be no difficulty in maintaining the face. No posts or other timbers are placed between the conveyor and the face of the coal. As soon as the shot is loaded out, the face is cut and the conveyor is advanced 3 or 4 ft. The recovery was about 97 per cent. The life of the conveyor will probably be about five years. It may, outlast, however, the expectations of the company.

O'Toole Machine Cuts And Loads Fifty-five Tons in Thirty Minutes

A machine that cuts and loads coal from a 45-ft. longwall face and which has been in successful operation for about six months under a cover that has reached 750 ft. was the designation given by H. N. Eavenson in describing the O'Toole machine. The strata above the coal are of sandstone and slate. At first they break with difficulty, but after a fracture has been obtained the roof breaks quite satisfactorily.

Mr. Eavenson, in the absence of Col. Edward O'Toole, then introduced his son. Mr. O'Toole said the machine both cut and loaded coal. As his father was not entirely satisfied with it and as it is not yet on the market, he was not ready to describe its operation in detail. The cutter bar on the machine was 50 ft. long. It cuts the coal without shooting. The coal as it falls, is caught by a conveyor, carried to an entry and dumped into a string of cars hauled past the end of the conveyor.

DIFFICULTIES ENCOUNTERED

Being the first machine of its kind the machine has not been operated without difficulty. The best performances obtained from it have been 55 tons in 30 min.; 320 tons in 8 hours; 620 tons in 24 hours; 718 tons in 32 hours, 7,000 in a month. The difficulties of cutting, loading and hauling have all been satisfactorily solved, but the control of the roof still presents difficulties. When it is remembered that the space that must be kept open in front of the coal is 6 ft. wide and 45 ft. long and that the roadways increase that width it will be realized that under heavy cover a difficult problem remains to be solved.

Hydraulic jacks 6 ft. apart are used to advance the cutter bar each working on a screw which is 8 ft. long and is operated by the mechanism on the machine. When the cutter bar has progressed as far as the screw will permit, an arrangement enables a new hold to be taken. The jacks have, however, not solved the roof trouble. The coal mined is the No. 3 Pocahontas seam, but Mr.

O'Toole believes the machine would cut and load any other seam satisfactorily. The coal only occasionally has to be shot down, the weight of the roof shearing it as the cutter advances into it.

Conditions in Europe Much Different from Ours

George S. Rice said that a study of European conditions could not afford us much in the way of suggestion as to the use of longwall. In Europe the coal companies had really little choice. Room-and-pillar workings are well-nigh impossible of operation after the depth exceeds 1,200 ft.

For this reason you find little else than longwall both in England and on the Continent. Careful and close timbering is necessary. In Belgium and France it is found necessary to carry stringers parallel to the face on lines of props 3 ft. apart. Furthermore cross pieces must be laid on those stringers to carry the weight over the coal face, the ends of the stringers being set in the face of the coal. Temporary props are set up which have to be removed after the coal is shot down.

In most places in England the cutting machine works between a row of chocks and the face; the conveyor is placed behind the chocks, and back of this conveyor are the packwalls. With roof such as is found in Great Britain, Mr. Rice believed, it would be impossible to operate a longwall face without backfilling. The face could not be kept open. In fact the British engineers are unable to work on the end of the coal and they have, even with this precaution, to use strong breaker props and keep their packwalls close to the face. Conveyors are not by any means new in Europe. "In 1911," said Mr. Rice, "I saw shaker conveyors in the thin beds of Scotland. They work nicely in a pitching bed."

State Rys. Consume Two-Thirds Of Rumania's Coal

Coal production in Rumania in 1923, together with the amount of coal reported to have been consumed by the Rumanian State Railroads, according to a report by Acting Commercial Attaché Louis E. Van Norman, Bucharest, was as follows, in metric tons:

	Total Production	Consumed by State Railways
Bituminous coal.....	1,562,423	1,164,917
Lignite, superior.....	236,736	146,276
Lignite, inferior.....	328,923	270,528
Coal produced from the mines at the "Reshitza" Metal- lurgical Works — grades not specified.....	237,986
Total.....	2,366,068	1,581,721

Practically all of the balance was consumed by industrial enterprises and private users in Rumania.

NOTE — Discussion of "Correlation of Mechanical Loading with Haulage and Mining Systems" at Cincinnati Conference and Exposition, American Mining Congress.

News Of the Industry

Wholesalers' Convention Indorses Move For Coal Institute

**Wadleigh Proposal Warmly Approved—Covel Says Tide Has Turned
from Oil Back to Coal—Snider Discusses Freight Problems—
Correction of Cost and Credit Evils Urged**

That the wholesale coal men are ready to co-operate in a movement looking to the organization of a coal institute which would take rank with such institutes in other industries in this country and Great Britain was evidenced by the action taken at the eighth annual convention of the American Wholesale Coal Association, held at White Sulphur Springs, W. Va., June 3 and 4. Following an address by F. R. Wadleigh, vice-president of the Tuttle Coal Corporation, New York, and formerly Federal Fuel Distributor, outlining the activities of the suggested Coal Institute, the convention unanimously approved and indorsed the establishment of the institute and referred the matter to the Trade Relations Committee of the association for action.

Tells Need of Coal Institute

Mr. Wadleigh pointed out the value the Institute, or Federated Coal Association, if that name should be chosen, would have in bringing about much needed solidarity, cohesion, co-ordination and co-operation in the industry, "and a realization of the value and importance of each branch of the industry to the whole, a knowledge of its own power, if and when united." Two important lines of work which should be taken up by the industry now, he said, are education of the public and its representatives, and research, economic and technical.

Discussing the research phase, Mr. Wadleigh quoted from an editorial in *Coal Age* bearing upon the necessity for greater information in the coal industry and referred to another article listing about 50 subjects needing particular study to advance methods connected with the production and distribution of coal.

Mr. Wadleigh's address was a feature of the first day's session and was followed by another outstanding speech of the convention, made by Borden Covel, president of the Northern Coal Co., of Boston, on "Oil Competition in the Coal Game." Mr. Covel spoke of the inroads fuel oil had made into the coal business of the New England states, but expressed the opinion that the tide had turned and that most of the former coal customers would return in the next four or five years. Giving many facts and figures on both sides of the ques-

tion as a result of a thorough investigation into the oil and coal situation, Mr. Covel summed up the advantages of coal burning as follows:

- (1) More stability in the price of coal and in production.
- (2) Railroad-car equipment now in

Charles L. Dering

Retiring president of the American Wholesale Coal Association, succeeded by H. K. Cortright, of Philadelphia.

excellent condition and likely to remain so.

- (3) Much less fire risk.
- (4) Storage of coal is more flexible.
- (5) Cost of installation is less in smaller plants.

In the discussion that followed Mr. Covel's talk the feeling that the peak of oil competition had been reached was reflected by most of those who took part. Dr. E. W. Parker, of the Anthracite Bureau of Information, Philadelphia, called attention to the fact that the oil refiners themselves were using coal rather than oil in the refining processes. W. C. Baxter, of Troy, N. Y., was one of those at the convention who felt that the impracticability of oil burning for household heating purposes made any prospect of falling off in this trade negligible.

Reports from the association's officers relating to the work done during the

past year occupied the remainder of the first day's program, which closed at noon in order to give the visiting members an opportunity to try out the famous Greenbrier golf courses.

Much of the discussion at the second meeting centered on freight rates, diversion and reconsignment. G. N. Snider, former coal traffic manager of the New York Central R.R. but now general manager of Dickson & Eddy, New York, in his address "Freight Rates—Diversion and Reconsignment," advised that all transportation problems be settled by direct dealings with the railroads as far as possible rather than by seeking relief, of which he felt there was little hope, through government bureaus. He suggested that perhaps the mass of appeals made to the Interstate Commerce Commission had strengthened the feeling that regulation has become a burden and worked toward petrification in the present structure.

Cochran Deprecates Squabbling

Ira Cochran, the association's commissioner, urged that as there were varying problems with regard to these transportation matters in the different sections, the coal leaders should stop arguing and study the coal and the railroad situation. E. S. Simpson, of Richmond, president of the West Virginia Coal Co., complained of a lack of commercial mind among railroad men, and said that reconsignment was not now flexible enough, that the railroads should be more liberal, not penalizing operator or wholesaler, but should work back to pre-war conditions. More elasticity was declared to be the present need by E. M. Platt, president of Platt & Brahm Coal Co., of Chicago, who said that he saw no reason for restricting the use of the facilities of the roads.

Mr. Platt was one of the speakers on Wednesday, his subject being "Costs and Credits." Speaking of the evils of excessive competition which have developed and the "extreme general disorganization that unquestionably exists in the coal trade," Mr. Platt said: "Neither operator nor distributor can hope to get on a firm basis of prosperity until these conditions have been corrected. . . . Manifestly if we could move back toward a rational reorganization of the industry, that would re-establish the distributing sales end of the business in its proper place—between the producer and the consumer, where it would naturally regulate production to a fair relationship of legitimate demand and consumption—these problems of cost and credit would solve themselves both for the distributor and the producer, and with

such a sales body functioning efficiently and adequately the producer could apply his energies and his abilities unrestrictedly to the problems of producing coal and getting a price for it that at all times would net him a profit in fair proportion to the hazards of the business.

"The distributor, on the other hand, if relieved of the handicaps of excessive competition should be able to develop an efficiency that would enable him to handle at a profit to himself the product of the operator better and cheaper than the producer could handle it himself."

Another speaker on the program was Owen Meredith Fox, associate editor of the *Black Diamond*, who spoke on "The Wholesaler of the Future."

Presiding during the convention until the election and installation of new officers at the closing session was President Charles F. Dering, of Chicago. After the report of the nominating committee was adopted, he turned over the gavel to H. K. Cortright, of the Cortright Coal Co., of Philadelphia, who will serve as head of the association for the coming year. Other officers elected were H. J. Heywood, of W. A. Gosline & Co., Toledo, vice-president; and G. H. Merryweather (re-elected), of the Waubun Coal Co., Chicago, secretary and treasurer. Ira Cochran, the association's commissioner, with offices in Washington, was reappointed, and he as well as the retiring officers was given a vote of commendation.

New Directors Chosen

Directors who will serve for the coming year are: G. H. Snowden, of the G. H. Snowden Co., Pittsburgh; W. H. Weller, Jr., U. S. Fuel Corporation, Birmingham; E. H. Hemingway, W. C. Mason & Co., Inc., Hartford; Benjamin H. Read, Lynch & Read, Baltimore; J. W. Dykstra, of J. W. Dykstra & Co., Detroit; W. B. Vaughan, Ransom Coal & Grain Co., Kansas City; F. S. Martin, of F. S. Martin & Co., Omaha; H. P. Smith, Midland Coal & Steel Co., Cleveland; C. C. Cole, Cole-Basinger Coal Co., Toledo; W. H. Prescott, Memphis Coal Co., Memphis, Tenn.; J. Edgar Long, J. E. Long Coal Co., Clarksburg, W. Va.; W. C. Mass, Galloway Fuel Co., Milwaukee; C. G. McGill, Wm. McGill & Co., Toronto; L. S. Platka, E. S. Adsit Coal Co., Burlington, Vt.; J. F. Irwin, of J. F. Irwin Fuel Co., Latrobe, Pa.; L. S. Leighton, Carbon Coal & Coke Co., Boston; G. N. Snider, Dickson & Eddy, New York; Arthur Kuppinger, Seaboard Fuel Corporation, Philadelphia; F. W. Legg, Logan & Kanawha Coal Co., Cincinnati, and R. J. Buck, Jr., Marcy-Buck Co., Inc., Watertown, N. Y.

The executive committee will be made up of G. N. Snider, L. F. Leighton, G. H. Snowden, J. W. Dykstra, H. P. Smith, Fred Legg and W. H. Weller, Jr.

The association's annual banquet, held on the evening of June 3 in the main dining room of the Greenbrier Hotel, was attended by about 125 members and their wives. Jay Johns, of Pittsburgh, chairman of the Convention Committee, was in charge of the dinner, which was voted an unusually successful affair. No attempt was made to discuss business problems, and

Toastmaster Noah H. Swayne, of Philadelphia, soon disposed of the few serious remarks he felt it incumbent upon him to make. Roe Fulkerson, editor of the *Kiwanis Magazine*, Washington, D. C., was the principal speaker, his subject being "Personality." "The battle of business," he said, "is not that of dollars but of personalities," and then made many amusing applications. Mr. Swayne also introduced Major W. R. Coyle, of Bethlehem, Pa., a charter member and former president of the association and now a candidate for Congress. Major Coyle, in his greeting, caused much laughter when, after referring to the response of the coal men during the war, he spoke of the adjustment in the coal industry to peace and said: "We are now almost at peace with the government."

A large number of the delegates to the wholesalers' convention left White

G. N. Snider

Now general manager, Dickson & Eddy, formerly coal traffic manager, New York Central, urged seeking remedies for coal ills through railroads rather than through the Commerce Commission.

Sulphur Springs Wednesday afternoon for Bluefield, W. Va., to attend the retailers' convention there.

Before adjournment it was unanimously voted to adopt the report of the Resolutions Committee which requested the Interstate Commerce Commission and the individual railroads to restore at as early a date as possible those reconsignment and demurrage practices which through long-established custom had built up proper and necessary trade practices in various parts of the country, and commended the Trade Relations Committee for its continuous good work during the past year, requesting that the committee continue its co-operation with committees of other branch trades to the end that some workable plan of universal inspection at destination, if and when required, may be put into practice. The resolutions also recommended that the association approve and indorse the establishment of a coal institute as presented by F. R. Wadleigh and refer this question to the Trade Relations Committee for action.

The work done by Ira C. Cochran, in the presentation of claims and the preparation of claims for presenta-

Safety Movement Gains Headway in Utah

It is stated that most of the coal mines of Utah are now using water to keep down dust in the cutting, loading and hauling of coal, according to a report of State Coal Mine Inspector John Crawford. Mr. Crawford said the recent orders of the Industrial Commission in respect to safety devices also were being complied with as rapidly as possible.

tion was highly praised. It is perhaps worthy of note that during the past year there have been over 400 individual claims for freight charge corrections and reimbursements prepared by, and in many cases presented by, Mr. Cochran, for the membership. He is ready to consider and handle an even larger volume of these matters in the future than in the past. The work of Mr. Johns, of Pittsburgh, in planning for the convention received much favorable comment.

The association again indorsed the plan of the Arbitration Society of America and expressed its appreciation of the work done by many of the officers and members during the past year in procuring the amicable settlement of trade disputes. The action taken by the Executive Committee and the officers of the association in relation to the U. S. Coal Commission and its report was approved and the officers of the association came in for high praise for their work for the organization during the past year.

North American Fuel Co. to Run on Open-Shop Basis

Closely on the heels of a resumption of operations at the Brady mine of the Brady-Warner Coal Corporation in the Monongalia field of West Virginia, comes an announcement by the North American Fuel Co., operating at Maidsville, in the same field, that its mine will resume operations on an open-shop basis and with the 1917 wage scale in effect. Operations will start as soon as the company can obtain possession of houses now occupied by miners identified with the union. The company has served notice on employees that they must either return to work or vacate company property. B. M. Chaplin, president of the company, says that the same course of procedure as employed by the Brady-Warner Corporation will be followed by the North American company and that miners would be evicted from company houses and the houses used by those who would work. The North American company, like the Brady-Warner Coal Corporation, declined to become a party to the Baltimore wage agreement.

Since the outbreak on May 22 at the Brady mine of the Brady-Warner Coal Corporation when 50 shots were fired, there has been no further trouble, inasmuch as the company is proceeding under a sweeping injunction. By May 24 nearly all the miners who had refused to return to work had been moved from company premises.

Pittsburgh & West Virginia To Segregate Coal

The Pittsburgh & West Virginia Ry. is said to be considering segregation of its coal properties. It owns 15,000 acres of coal lands in Allegheny and Washington counties, Pennsylvania, through ownership of the Pittsburgh Terminal R.R. & Coal Co.'s \$16,000,000 stock. The coal lands are estimated to be worth \$15,000,000.

The Pittsburgh & West Virginia Ry. owns sixty miles of main line in Harrison County, Ohio, easterly through Harrison and Jefferson Counties, Ohio; Brook County, West Virginia, and Washington and Allegheny Counties, Pennsylvania.

Properties of the Pittsburgh Terminal R.R. & Coal Co., the entire capital stock of which is owned by the Pittsburgh & West Virginia Ry., are located along the line of the Pittsburgh & West Virginia and the West Side Belt R.R., also owned by the P. & W. V.

Total coal holdings of the Pittsburgh Terminal R.R. & Coal Co. are estimated at 72,500,000 tons.

Franklin Coal Co. Charged With Unfair Methods

Unfair methods of competition in the marketing of coal is charged against the Franklin Coal Co., of St. Louis, Mo., in a complaint issued by the Federal Trade Commission.

It is alleged in the complaint that the concern offered for sale certain coal under the trade name of "Mt. Olive coal" and "Mt. Olive district coal." The complaint states that coal mined at Mt. Olive, Ill., or the immediate coal district in the region of Mt. Olive, known as the Mt. Olive section, which lies within the counties of Macoupin and Madison, is known to and designated by a substantial part of the purchasing public as "Mt. Olive coal." The complaint alleges that respondent's coal has a lower market value than Mt. Olive coal, and that the use by respondent of such misleading designation has a tendency to deceive the purchaser into the erroneous belief that its coal is the product of the Mt. Olive district, whereas it is alleged that the respondent's coal is produced in the counties of Clinton and Bond, in the State of Illinois, this district being wholly outside the Mt. Olive district.

Stone's Attitude Heartens Partisans of Trade Data

Those most concerned as to the trade-association statistical situation are much encouraged by the attitude of the new Attorney General. Mr. Stone has stated publicly that he is hopeful of a satisfactory solution of the matter. There is reason to believe that he recognizes that the policy of the department toward these figures has not been constructive. At the same time the Attorney General is not in a position, it is believed, to discuss his views in detail at this time because of their possible application to pending cases.

It now seems probable that a test case will be brought, although that step will not be taken in the immediate future. In the meantime, consideration is being given to expediting some of the pending cases in which certain important trade-association questions are involved.

Cleveland & Western Coal Co. Judgment Stands

The Supreme Court has refused to grant a writ of certiorari sought by the Cleveland & Western Coal Co. to review the judgment awarded against it to the Main Island Creek Coal Co., of West Virginia. The decision of the lower courts, awarding judgment of \$404,279 to the Main Island company therefore will stand.

The Main Island company sued the Cleveland & Western to recover \$6 per ton on 60,711 tons of coal delivered to the Cleveland & Western in 1919. The Cleveland & Western alleged that the arrangement was for an exchange of coal. It tendered coal to the Main Island company and upon refusal to receive the fuel sold it and tendered the money to the Main Island company. The Main Island company claimed the original deliveries were in the nature of outright sales and the District Federal Court so held. This decision will prevail through the declination of the Supreme Court to review the case.

Shipping Board Opens More Bids at New York

The United States Shipping Board at New York opened bids on June 5 for furnishing and delivering alongside vessels in that harbor on June 8, 3,300 gross tons of soft coal of a minimum of 14,500 B.t.u. There were five bidders, as follows: Rhodes Fuel Corporation, 5.18; Seiler Coal Co., \$5.43; Imperial Coal Corporation, \$5.14; Steamship Fuel Co., \$5.04; W. H. B. Haff, \$5.29.

Bids will be received until July 2 by the Quartermaster at West Point for furnishing 17,000 tons of birdseye coal, 1,400 tons No. 1 buckwheat and 1,200 gross tons gas coal.

Bids were opened on June 6 by the Quartermaster's Department at the U. S. Army Supply Base, South Brooklyn, for furnishing and delivering approximately 7,000 tons of soft coal to various forts and army buildings in New York, Pennsylvania, New Jersey and Delaware. More than thirty bids were received, quotations ranging from \$1.26 to \$2.34 per net ton f.o.b. mine, depending upon quality of coal and place of delivery.

Welsh Coal Seeks Canada's Anthracite Market

British and Canadian coal interests are trying this year to popularize Welsh and Scotch coal in eastern Canada so as to replace some of the American anthracite sold in that region. They claim they can sell the cross-water fuel at prices that will compare favorably with the Pennsylvania product. To companies are preparing to handle this traffic—the Canadian-Welsh Anthracite, Ltd., which is now building a \$200,000 crushing and sizing plant at Vulcan wharf, in Montreal, and the F. P. Weaver Coal Co., Ltd., which also will build a breaker at Montreal, according to the Department of Commerce.

During the year ending Feb. 29, 1924, Canada imported from the United States 4,950,000 tons of anthracite and 15,320,000 tons of soft coal. From the United Kingdom came only 211,300 tons of anthracite and 278,500 tons of bituminous coal. Those now engaged in the Canadian Welsh coal business are prophesying that during the present year they can at least double the import of British coal into Canada.

In parts of eastern Canada a real effort is being made to replace American anthracite with Canadian coke.

Retailers, in Annual Convention, Decry Government Interference with Coal

Strong Resolution Deprecates Attempts at Bureaucratic Control—Senator King Deplores Burdensome Taxation That Handicaps Business—Association Officers All Re-elected

The business sessions of the seventh annual convention of the National Retail Coal Merchants' Association were brought to a close at the Hotel West Virginian, Bluefield, W. Va., late Thursday afternoon, June 5, with the election of officers and the adoption of three important resolutions outstanding among a dozen or more which the convention indorsed.

Regarding governmental interference with the coal industry a resolution was adopted calling upon the executive officers of the association to oppose by all legitimate means legislation tending to place the coal industry under governmental or bureaucratic control, and urging upon members of all branches of the coal industry the practice of such business ethics in their relations with one another that government regulation of the industry will be unnecessary.

Want Fewer Government Workers

Offered by Roderick Stephens, of New York, and adopted by the convention was a resolution urging members of the association to use their influence upon all citizens and other civic and commercial organizations throughout the nation to voice an insistent demand for immediate and continuous reduction in the number of government employees, both of the state and nation; and further, urging support of the movement by the discouragement of the assumption of additional governmental functions and responsibilities, and by encouragement of a heightened sense of responsibility by individual citizens as the only sound and permanent basis for the preservation of our liberty and for the growth and prosperity of the country as a whole.

A resolution calling for the rescinding of the ten percentum overload rule and the substitution therefor of a rule which will provide for a minimum of ten percentum less than marked capacity and a maximum of the marked capacity with the peak of the load not to exceed 12 in. above the side of the car was unanimously adopted.

The convention opened Wednesday morning, June 4, with more than 450 delegates and visitors in attendance. Two special trains, one from the East and one from the West, brought the delegation to the convention city. The convention was formally opened at 11 a.m., by Samuel B. Crowell, president of the association. The morning session was devoted to the appointment of committees and the hearing of reports by the officers. The outstanding feature in these reports was the splendid condition reported by the retailers considering recent reports of the state of the industry.

At the noonday luncheon, Clarence E. Ridley, City Manager, welcomed the delegates and visitors on behalf of the city of Bluefield, and H. I. Shott, editor of the *Bluefield Daily Telegraph*, ex-

tended the welcome on behalf of the people of southern West Virginia.

On Wednesday afternoon reports on trade relations were heard, President Samuel B. Crowell speaking on anthracite, and in the absence of Marshall Keig his paper on the bituminous situation was read by the resident vice-president, Joseph E. O'Toole.

A brisk and interesting report of the governmental relations committee was

©Champlain Studios, N. Y.

Samuel B. Crowell

President of the National Retail Coal Merchants Association. Mr. Crowell has been 38 years in the coal business, as an operator, wholesaler and retailer. He is now at the head of one of the largest retail coal companies in Philadelphia.

made by Roderick Stephens. Pointing out that since the last convention the committee had been working along familiar lines, except that there had been little to do of late in connection with general legislation, on account of the congressional oil deluge, complicated by a mud-slinging campaign of certain groups in the upper and lower houses of Congress, Mr. Stephens said much legislation aimed at the coal trade had been introduced, but no hearings had been held on bills of direct interest to the retail coal trade and no such legislation had advanced far enough to cause any concern. Mr. Stephens reviewed matters which had received the attention of the committee during the past year, among which were the U. S. Coal Commission, governmental activity in connection with the anthracite strike, the Federal Trade Commission, the Department of Commerce and the Government Fuel Yard.

Addresses by E. L. Greever, general counsel of the Pocahontas Operators Association, and George H. Cushing, editor of *Cushing's Survey*, brought the afternoon of the first day of the convention to a close. Mr. Greever spoke with reference to the Pocahontas coal

field and Mr. Cushing on "Ethics for Coal Men."

The annual banquet of the association Wednesday evening was featured by an address of Senator William H. King, of Utah. Senator King spoke on "What Policy Is Necessary for Business Revival." He opened with a recital of the burdensome taxation imposed by national, state and local governments, declaring a tax-ridden people cannot have prosperity, and said: "We want a government that lays its hand as lightly as possible upon the body of the individual, upon the liberty of the individual, and upon the purse of the individual." The speaker pointed out that among the things essential to the revival of prosperity was foreign trade and commerce. He urged a modification of the tariff law, denounced the child labor law and concluded with the statement that he applauded President Coolidge when he said we must enter the World Court and take part in the problems of the world.

Urges "Fight for Life"

Harry L. Gandy, executive secretary of the National Coal Association, and Francis R. Wadleigh, vice-president of the Tuttle Coal Corporation and former U. S. Fuel Administrator, were the principal speakers on Thursday. "These days are uncertain ones politically," stated Mr. Gandy, "in that there is an effort to increase the burdens of the government. On every hand there are schemes to broaden governmental activities and increase expenditures. This race of ours through centuries of effort, finally shook off the bondage of the state and made possible individual initiative and the private ownership and control of profits. Indeed if ever there was a time when American citizens should read their histories, this is the time." The speaker urged everyone engaged in the coal industry to exert his best efforts not only for the success of the industry but also in order that the industry may hold respect and confidence and continue its usefulness. "The fight for life," he said, "makes this necessary."

Mr. Wadleigh spoke on "The Coal Institute," making a strong appeal for the formation of the coal institute or some similar organization through which all branches of the industry could work in harmony.

On Thursday night the Pocahontas Operators Association, host to the 1924 convention, tendered a banquet to the delegates and visitors. Colonel W. S. Battle, of the Norfolk & Western Ry., presided as toastmaster and delivered a fine address, setting forth some truths affecting the problems of the railroad as related to those of the coal shippers. A cabaret entertainment was given in connection with the banquet.

On Friday, June 6, members of the National Retail Coal Merchants Association visited the Pocahontas coal fields in southern West Virginia. The party made the trip by automobile. Among the plants visited were those of the American Coal Co. and the Pocahontas Fuel Co.

The officers of the association, who were re-elected without a change, follow: President, Samuel B. Crowell, of Philadelphia; Resident Vice-President,

Joseph E. O'Toole

Resident vice-president, National Retail Coal Merchants Association, succeeds himself. Mr. O'Toole reports that during the year ten local associations affiliated with the national society, including the Baltimore Coal Exchange.

Joseph E. O'Toole, of Washington; Vice Presidents, Marshall E. Keig, Chicago; J. Maury Dove, Jr., of Washington; W. A. Clark, of Boston; W. L. Vail, of Toledo; Chas. B. Staats, of Albany; F. W. Schermes, of Kansas City. R. J. Wulff, of Brooklyn, N. Y., was re-elected treasurer of the association.

Board of Directors: Homer D. Jones, chairman, of Chicago; Elijah J. Barkume, of Detroit; Jos. H. Lucking, of Newark, N. J.; John S. McEwan, of Albany; Chas. B. Bodwell, of Manchester, N. H.; W. R. Fouguay, of St. Joseph, Mo.; J. Harry West, of Baltimore; A. Ashley Miller, of Chicago; John J. O'Connor, of Milwaukee; Wellington M. Bertolet, of Reading, Pa.; J. L. Browne, of Sioux City, Ia.; H. E. Davis, Woonsocket, R. I.; C. A. Elwood, Rochester; W. L. Montgomery, Harrisburg, Pa.; C. D. Taylor, of Kalamazoo, Mich.; James T. Tattersall, of Trenton, N. J.; John E. Loyd, of Philadelphia; C. Solon Kellogg, of Rochester; Roderrick Stephens, of New York city; F. S. Sager, of Norfolk; Ray Macy, of Indianapolis; Russell H. Jones, of Kenosha, Wis.; Robert S. Hayes, of Newport, R. I.; L. W. Ferguson, of Chicago; Luke D. Drury, of Richmond; G. F. Rogers, of St. Catharines, Ont., Canada.

President Crowell was retained by the association as chief counsel in the United States Chamber of Commerce, and after his election he urged that more men be appointed to this important duty. It was then on motion ordered it be left to the president to name whom he might on this committee.

Following the re-election of President Crowell delegates and members of the association gave him a big demonstration of their appreciation for his work during the past year. In accepting the presidency Mr. Crowell made an eloquent address. He spoke of the splendid success of the association, the fine spirit of co-operation extended him during his administration and then requested there be more effort put forth along this line during the coming year.

Says Railroads and Coal Men Should Bury the Ax

In his appeal for less antagonism between railroads and the coal industry, at the International Railway Fuel Association convention, in Chicago, May 29, F. R. Wadleigh, former Federal Fuel Distributor, pointed out some of the penalties that are paid for such mutual feeling, and indicated ways of removing those penalties.

"It seems to me," said he, "that railroad purchasing agents would obtain better results for their roads if they studied more closely the interests of the coal industry and made themselves better acquainted with its problems and relationship toward transportation. The coal industry should not feel antagonistic toward railroad-coal purchasers, but such a condition unfortunately exists.

"The practice consistently followed by some railroad-fuel purchasing officials of 'beating down' the coal sellers to the very lowest price in times of plentiful supply is not economic from a business standpoint, nor is it best for the railroads in the end. It, of course, antagonizes the coal seller and encourages him to 'put one over' on the railroads in any way possible; it makes for poor preparation and poor results. When there is a scarcity of coal the railroads are apt to suffer and be given the least consideration, not only in price but in quality of coal.

Coal Man Partly at Fault

"It is freely admitted that the coal man is partly to blame. His attitude toward the purchasing officer and his inspectors is not always calculated to bring about friendly feelings. He sometimes—too often indeed—looks upon the railroads as a dumping ground for his coal, a place where badly prepared or lower grade coal can get by, not perhaps realizing that we are all, producer and consumer alike, bound up in railroad transportation; that poor coal slows up train movement and thus hampers every industry, including his own.

"The American Railway Association has recently appointed a fuel committee; could it not study the subject of coal purchases and formulate purchase methods, with benefit to its members?

"I might suggest here the possibility of that association's formulating a standard contract form and general specifications for coal. Although some of our friends in the coal industry would object to such a move, I believe that it would, if properly carried out, inure to the benefit of both buyer and seller.

"Undoubtedly, the International Railway Fuel Association could do a great deal to remedy the existing conditions.

George H. Cushing

Philosopher of the coal trade. Mr. Cushing is "shocked by the hypocrisy of public men who preach ethics to coal men yet seek to plunder the industry for their own advancement."

It could at least appoint a strong committee, in which might be included representatives of the coal operators who are members of the association, to study the matter and make recommendations to the railroads and to the coal industry. There is no group more interested in the coal purchases of the railroads than the members of this association; their wide knowledge regarding both purchases and the use of the coal purchased should make their recommendations carry great weight. The coal industry would, I am sure, co-operate with them and give careful consideration to their recommendations.

"In this connection, it will interest all of you, I believe, to learn that there is a movement on foot to organize a Coal Institute (tentatively so named) which shall actually represent all branches of the coal industry, operators, wholesalers and retail dealers. With such a body this association might well co-operate on the subject of railroad-fuel purchases, as well as in other ways, to mutual advantage.

"Needed and effective co-operation between the railroads, their transportation, traffic, coal-purchasing officials, inspectors and the coal industry generally has been difficult owing to the lack of unity on the part of the latter. Had the coal industry a truly national and representative body, as well organized and operated, with the comprehensive functions of the American Railway Association, the interests of both could be signally advanced. It is hoped that the Coal Institute, if created, will be of great help in that connection."

Transfer of Mineral Resources Division To Census Bureau Meets Opposition

Reorganization of Federal Executive Departments Would Take Compilation of Coal Statistics from Geological Survey—Industry Has Six Months to Study and Acquaint Legislators with Its Views

By PAUL WOOTON
Washington Correspondent of *Coal Age*

The scheme for the reorganization of the executive departments of the federal government, which was submitted to Congress just before adjournment, meets with disapproval in coal circles, at least in so far as it proposes to transfer the Division of Mineral Resources from the Geological Survey to the Bureau of the Census. One of the major sections of the Division of Mineral Resources is devoted to coal statistics.

Under the reorganization plan the name of the Bureau of the Census is to be changed to the Bureau of Federal Statistics. In this bureau are to be grouped practically all of the statistical activities in Washington. Coal statistics are so dependent upon close association with the technical staff of the Geological Survey that to attempt to place them in the hands of isolated statisticians instead of geologists who have had statistical training has brought forth a determined protest. It would be just as sensible, it is contended, to set up a bureau of type-writing and have the typing for all of the government departments done in a single building.

Change Would Be Scientific Loss

The reorganization proposal may never be written into law, but the plan is now on the calendar of both the Senate and the House and can be called up for action soon after the convening of Congress in December. This has the advantage of giving industry six months to study the plan and to acquaint the legislators with its views.

The removal of the mineral resources work from the Geological Survey would mean a serious loss to the scientific work of the bureau through dissociation with current statistics. The two are held to go hand in hand and have been handled with entire satisfaction to industry during the thirty years that the work has been conducted by the U. S. Geological Survey. The Bureau of the Census has made a great success in the handling of many types of statistics, but in the case of coal and mineral statistics generally it has been found that they are compiled best by those who have to use them.

Every ten years the Bureau of the Census publishes as a volume of the decennial census an extensive report dealing with statistics of mines and quarries. This is a pretentious work. The volume dealing with mines and quarries in 1919 contained 443 compactly printed pages. It happens that because of the detail to the Bureau of the Census of Frank J. Katz, a geologist who has had long experience with the mineral resources work of the Geo-

logical Survey, these data were brought to a new plane of merit. Even then, however, the work is regarded as being far from satisfactory and it was only with great difficulty that Mr. Katz was able to bring the statisticians of the Bureau of the Census to accept even a portion of his program for handling these figures.

One of the leading economists of the country is on record to the effect that the 1909 Mines and Quarries report was worse than useless. He finally threw his copy in the waste basket so that his staff might not make use of figures likely to mislead them.

The point also is made that the creation of the Bureau of Federal Statistics will reduce greatly the amount of money which will be made available for statistical work. When most of the statistical activities are grouped together, the aggregate of their present expenditures will look large to the appropriations committees. The lump sum which would be made available for all of this work in all probability would be reduced. The coal statistics would be a small activity in a very large Bureau. Its proportion of the total made available to the Bureau almost certainly would be much less than is now expended in this connection.

Most of the arguments advanced against the transfer of coal statistics to the Department of Commerce apply equally well to those of other minerals. Long experience has demonstrated the advisability of having these statistics prepared by those who must use them in their daily work dealing with the technical and scientific phases of those industries.

OIL VERSUS COAL

All is not "pie" for the railroad that burns oil instead of coal, as was brought out often in the coal and oil symposium at the International Railway Fuel Association meeting in Chicago. It was shown that nearly every oil field is declining in production and price increases are expected. The steady increase in the "crackling" process to make more gasoline reduces the free burning quality of fuel oil and makes more carbon troubles. Among the disadvantages of oil firing not commonly considered, J. M. Nicholson, of the Santa Fe, pointed out that the average life of fireboxes is reduced 25 per cent by oil. The 1923 decline in steam-coal prices and the uncertainty of oil supply make the railroad oil market weaker than that for coal, it was said. Last year American roads burned 146,000,000 tons of coal and 54,000,000 barrels of oil, equivalent to about 15,000,000 tons of coal.

Two Investigations Into Cause of Glen Alden Mine Explosion Now Under Way

(Special Dispatch to *Coal Age*)

Scranton, Pa., June 9.—Two official investigations are now under way into the cause of the gas explosion at the Loomis Mine of the Glen Alden Coal Co., in Hanover township, last Friday, causing the deaths of fourteen men and injuries to seven others. The Department of Mines is conducting one of the probes under the direct supervision of its chief, James J. Walsh, and the Glen Alden company is conducting a separate inquiry.

It is probable that the direct cause of the gas explosions will never be known because of the fact that the men who were on the scene of the first explosion were killed instantly. The mine is known throughout the region for its gaseous condition and Mr. Walsh, the Secretary of Mines, is quoted as having described the operation as "the most gaseous mine in the world." Very little water is found in the workings.

The explosions occurred in the Mills vein of No. 1 shaft, which is 760 ft. below the surface. It is believed that the first blast occurred in the second south gangway, and that the second, a result of the first, occurred in an opposite gangway, known as fourth east.

After traveling from the fourth east gangway, the explosive gases struck an air bridge and when the two currents were mixed it was stopped. The air bridge, which is of concrete and used to carry the air traveling on one road over the air circulation on a road in an opposite direction, was demolished by the force of the explosion.

Damage to the shaft was slight, but it was reported that brattice work was torn down, timber and props blown to pieces and numerous rock falls and caves followed in the wake of the explosions. There was no fire following the explosions. The shaft and mines were closed the day following the accident, but the breaker operated preparing the coal produced by several other mines owned by the company. About an hour after the explosion the first body was brought to the surface. It was that of William Welch, a brattice man, of Hanover Green. Between 1 and 6 o'clock six other bodies were taken from the workings.

Shortly after six o'clock all members of the rescue squads were ordered to the surface and the air currents were changed. At 9 o'clock a rescue party of forty men under the direct supervision of H. D. Dimmick, vice-president and general manager of the Glen Alden company, entered the mine and remained until the bodies of the other seven victims had been recovered. After entering the mine the rescue party spent several hours in erecting brattice work to keep back the gases and to handle the air currents. It was almost 4 o'clock on Saturday morning before the last of the bodies had been recovered.

W. W. Inglis, president of the Glen Alden Coal Co., was on the scene of the disaster until all of the dead had been removed from the workings.

To Resume Safety Hearings; Bill Embodies Bain's Plan

Further hearings on mine safety will be held by the House Committee on Mines and Mining when Congress reconvenes next December, as the committee was unable to conclude its inquiry into this subject before adjournment of the spring session, June 7.

It is evident that the members of the committee have been deeply impressed with the advisability of strengthening the Bureau of Mines, both as to extending the authority of that agency and as to supplying it with an increased appropriation for research, field work and added personnel.

Tells Needs of Bureau of Mines

In a statement sent the committee to be included in the printed record of the hearings, in order to supplement his personal testimony, H. Foster Bain, Director of the Bureau of Mines, suggested four outstanding needs of the Bureau according to his views. These are: (1) Legislative authority to carry the Bureau's safety messages and field demonstrations direct to those most vitally concerned; (2) authority for the publication of a brief annual specifically on safety to be sent to the miners themselves; (3) authority whereby the Bureau may investigate the manufacture, transportation and storage of explosives as relating to safety; (4) such authorization for additional mine rescue cars and stations and mine safety instruction cars as Congress may appropriate for.

Director Bain emphasized the fact that the Bureau now has a small staff for testing apparatus and equipment and that it lacks a sufficient field force for demonstration. The gap in its work in explosives, his statement showed, is that the Bureau now can take into account explosives only after they reach the mine. He called attention to the fact that the manufacture, transportation and storage of explosives are not now regulated. The Bureau is now so behind in its research and tests, owing to lack of personnel, that it is not in a position to frame a code for underground electricity, the director reports.

Stresses Need of Education

Special emphasis was laid by the director on the necessity for carrying on a campaign of education among both operators and miners by personal contact. The Department of Agriculture, Dr. Bain pointed out, sends to the individual farm its message, and something of the same nature should be done with the results of the safety work of the Bureau of Mines, he suggested. "If our mines are to be made safe, the scientific and technical data available to the federal government must be brought home in understandable form to the ones who alone can make it effective," said Dr. Bain.

A model law on mining to serve as the basis for state laws, as had been suggested by several witnesses before the committee, does not meet the ap-

All Indiana Talks Merger

The air is full of merger stories, the latest being that broadcast about a possible consolidation of practically the entire State of Indiana. This movement, urged by the Miami Coal Co. and other important Indiana companies, has not taken any definite form yet, but feelers have been sent out from an engineering office to collect general information about the properties and their probable valuations and at least one general meeting has been held of the principals in the case. Financial backing has been tentatively promised, but such a consolidation is a long way from completion and offers at present only a basis for interested discussion. Meantime, most of Indiana is shut down and there is nothing bright in the outlook for the state. By autumn, when coal demand picks up, the hope of certain backers of the Indiana merger is that enough properties will be under single control so that a great many that have no business operating can be prevented from muddling the market for the others.

proval of Dr. Bain, who, in his statement, suggests rather that there be an agreement on the general principles and standards of safety with a flexible system of regulation and orders to be issued as the need arises. The suggestion offered by Chairman Robsion, of the committee, that a conference of governors of states in which coal mining is conducted be held, in order to agree on certain principles of safety and the removal of certain competitive conditions which now hamper advancement of certain phases of safety work, is indorsed strongly in the statement of Director Bain.

Wants Voluntary Co-operation

In view of the limitations of federal authority over state mine inspection and regulations, Dr. Bain suggests legislation providing for a voluntary co-operative system by which the Bureau of Mines, on invitation of a state, might send trained personnel to assist the state department, the expense of work of this character to be divided between the state and the federal governments.

The Bureau of Mines is limited by law to ten mine rescue cars at present, the statement shows, and in the near future will be able to use to advantage twelve cars. Three of the old cars are unsafe for rapid travel and should be replaced, it is stated. Provision for one new steel car to replace one of these wooden cars is made in the appropriation available July 1.

A further suggestion is that a third instructor be added to each instruction car. The Bureau next year will ask \$325,000 for safety work, an increase of \$63,000.

In line with the director's suggestions, the Bureau of Mines has submitted to the committee a bill embodying Dr. Bain's ideas.

Rumbles of Protest Rise Against Northwest Rates

Now that the long awaited decisions have been made by the Interstate Commerce Commission on rail rates into the Northwest, the expected protests are being heard from the losers—the rail shippers. Furthermore many Northwest consumers are beginning to raise their voices also because the decisions, ordering higher rail rates from southern Illinois and eastern Kentucky into effect Aug. 21, may logically cause higher prices of both dock and rail coal immediately after that. Certain dock spokesmen already deny publicly that there will be any increase in the price of dock coal by reason of the rate advantage the commission gives them, but the consumers are fearful.

The peculiar features of the decision against rail shippers have aroused much comment. Although the rate into the Twin Cities themselves has not been ordered up, the new zone lines arbitrarily drawn south of the Twin Cities make it impossible for rail coal to retain the present Twin City rate. Instead of drawing the usual rate line from Stillwater, Minn., westward, thus in effect defining the rail territory from the dock territory, the commission drew two such lines. One is the curve of the C. M. & St. P. Ry. from Stillwater south and west of the Twin Cities. All rail coal reaching this line or crossing it bound north or west must pay \$3.75 instead of \$3.47. The second zone line south of this is the line of the Chicago & Northwestern through Winona, Rochester and Mankato. Coal into this zone must pay \$3.55 instead of \$3.47 and coal reaching but not crossing this line is boosted from \$3.22 to \$3.35.

The effect of the decision in the case of eastward coal traveling all-rail to the Northwest is to raise its rate 53c.

"What can we do?" is the wail among the parties affected by the increases. A definite protest to the commission by interests not previously heard may soon be made. But a more potent solution lies in the possibility of Midwestern lines declining to take advantage of the increases they can make under the decision. There are many other possibilities through rail action that are being discussed heatedly. No general policy by railroads has yet been determined.

Coal Consumption and Power Output by Utilities Drop

Electric public-utility plants consumed 2,936,727 tons of coal during April, according to a report by the Geological Survey. This compares with 3,241,631 tons consumed in March and 3,326,631 tons in February. Fuel oil consumed by utility plants in April totaled 1,208,735 barrels, compared with 1,540,256 barrels in March and 1,543,594 barrels in January.

The average daily production of electricity by public-utility power plants during April was 158,400,000 kw.-hr., about 1½ per cent less than the daily output in March. The output for February, 168,300,000 kw.-hr., was the highest on record.

Practical Pointers For Electrical And Mechanical Men

How Flashing of Substation Generator Was Stopped by a Choke Coil

Feeder System Was Unusually Good — Short-Circuited Resistance Was Small — Choke Coil Modified the Steep Wave Front — Quick-Acting Breaker Also Necessary

NEARLY everyone working in the electrical department of a coal company has at some time or other been confronted with a report of electrical trouble concerning which everything seemed to be correct but the apparatus wouldn't function properly. Many a mine electrician probably at some time or other has been told, by an inside workman, about a piece of equipment which was properly connected and installed but still refused to operate satisfactorily.

It is sometimes interesting to hear a member of the electrical engineering department try to determine the cause of an electrical failure by conversation, over the telephone. Many times I have heard these engineers say, after such a conversation, "Everything is all right but it won't work." The usual result is a trip to the mine to get at the source of the trouble.

There are occasions, however, where the cause of an electrical breakdown is very illusive. I have in mind a particular case where difficulties were experienced rather frequently but it was a long time before a real cause was assigned to the troubles.

The direct-current generator of a standard type motor-generator set, manufactured by a reputable company, would occasionally flash over and seriously burn the commutator and brush rigging. This generator delivered 550-volt direct-current energy to a mine load consisting of locomotives, hoists and pumps. The motor was of the synchronous type and received its energy from a 4,000-volt, three-phase, 60-cycle circuit.

When the generator flashed over no one seemed to know the cause or what led up to the trouble. Frequently when the damaged parts were examined the commutator would be found to be badly pitted, the brush rigging burned and an insulator on one of the brush studs would be charred.

Just as soon as these parts were repaired the machine would be started and no other damage could be found. Later the equipment would be put in service on the same load as previous to the delay and everything would go fine until perhaps a month or possibly a

year, when the same trouble would be experienced again.

After each breakdown exhaustive tests were made for grounds, short-circuits and open-circuits. The field coils were checked, the wiring to the circuit-breaker and into the mines was traced. Insulation tests were made, yet nothing unusual was detected.

Conversation with some of the men in the mines disclosed the fact that the generator flashed over whenever a sudden overload was placed on the trolley lines. Whenever a short-circuit or ground occurred the most serious trouble was experienced.

Following this clue a survey of the whole direct-current system was made and some interesting conclusions were

Fig. 1—Current-Limiting Reactance

Several turns of cable wound into the shape of a large choke coil caused the current to increase in value at a slow rate. This arrangement permitted the circuit-breaker to open when the current in the line was relatively small.

reached This particular mine is only one of many operated by the same company, however, it is the only one using 550-volt direct-current for inside service. The feeder wires and return circuits were in unusually good condition. All through the mine a very good voltage was always maintained. This was probably due to a fortunate circumstance. By error or intent the feeder system consisted of cables much larger than usually found around mines. The reason why I say there might have been an error on the part of some one laying out these distributing lines is that the cables looked as if they had been calculated for the usual 250-volt mine power supply.

Consequently, when an abnormal

overload occurred, due to a ground or short-circuit, a heavy current flowed through the system. The generator characteristic curves showed that the voltage compounded to a high value very quickly whenever the current in the line wires became excessive.

Obviously when a heavy load was suddenly applied the current tended to increase until it reached its short-circuit limiting value. It must be remembered that the cables were large and the short-circuit limiting resistance was therefore low. This fact, together with the rapid compounding characteristics of the generator caused the voltage and current to increase to very large values.

If we suppose that a short-circuit occurred at a point 1,500 ft. from the generator, even neglecting the compounding of the generator voltage, we can estimate the short-circuit current of the line. The resistance of 3,000 ft.—feeder and return—of 350,000 c.m. cable is approximately 0.09 ohms:

$$\frac{E}{R} = I \text{ or } \frac{550}{0.09} = 6,100 + \text{ amps.}$$

When we consider the fact that the instantaneous compounded voltage is much larger than 550 volts we can see that the current rises to a very great value.

Further inspection revealed that the direct-current circuit-breaker operated sluggishly, in fact, it seems quite possible that although it was set to open at 600 amps. the current probably could rise to 6,000 amps. before the circuit was actually opened. On 550-volt systems there is a tendency for the arc to hold to the breaker tips for a considerable period.

When the circuit is finally ruptured the current has increased to such a high value and the generator voltage is so high that the sudden collapse of the magnetic fields in the machine gives rise to a counter-voltage which causes a flash on the commutator.

The cause of these flashes is therefore due to several conditions. First, the short-circuit occurs near the machine; second, the generator compounds its voltage quickly, third, the circuit-breaker is slow in operating.

To correct these conditions it was not advisable to increase the circuit resistance, because of the greater power loss under normal operation, but a large choke coil was put in the line to cause the short-circuit current to build up slowly. A new quick-acting circuit-breaker was put on the substation control panel.

Since these changes were made there have been no further troubles. Fig. 1 shows the large choke coil which was

Fig. 2—How the Generator Flashes Were Stopped by a Choke Coil

The dampened wave represents the current surge before a choke coil was placed in the line. The modified wave front shows the effect of the choke coil. A_1 indicates when the slow-acting breaker opens and B_1 when the quick-acting breaker opens the circuit without a choke coil. A_2 and B_2

respectively represent the points where the breakers open the circuit when a choke coil is in the line. The coil therefore gives a time lag which delays the current and permits the circuit-breaker to open the line while the current value is low. In this way high currents are prevented.

made of several turns of 350,000 c.m. cable placed just outside the substation.

Fig. 2 shows what happened in the circuit before and after the changes were made. The slowly dampened wave represents the current curve and the counter current established in the system when the circuit is opened. If the time A represents the interval required for the current to reach its short-circuit value and if the sluggishly operated breaker takes this same amount of time to operate, then the conditions are very bad. The breaker

must then open the circuit when there are over 6,000 amps. flowing. Should the breaker open the circuit at the point B then the conditions are not so bad, because the circuit is opened when a much smaller current is flowing.

The dotted line shows the modified current wave front. Apparently even the same sluggishly operated circuit-breaker would now relieve the load on the circuit much better than before. A quick-acting breaker, which would function in time B , would relieve the machine of its load with little or no surge. E. B. CAMERON.

Welded Mine Indicator Made of Steel

The introduction and application of welding to mine repair service has rapidly spread. Those who at one time thought they had no particular use for welding equipment now find that they can no longer do without some form of welding device.

In the mine, where conditions at best are very bad, welded material effects great savings. One instance is the construction of road signs. Painted signs usually become black and dirty with dust, so at one of our mines we are building signs as shown in the illustration. The material used consists of sheet iron and the necessary hinges, all of which are welded to make the complete box.

Usually two or three electric lamps are installed inside the box and the word or words cut into the cover are always visible even at great distances. These lamps are frequently mounted in porcelain sockets which can be fastened to the base and made secure.

Depending upon the purpose of the box, letters are cut on the front. To guard against breakage and other loss a circuit is run to lamps which are located inside the box and the cover is locked on by a padlock.

The advantages of this arrangement are that the visibility of the sign does not depend upon the color of paint, lamps cannot be stolen, the sign cannot be broken and no unauthorized tamping is possible.

At another of our mines I have seen some interesting tool boxes made in this same manner. We also use similar boxes to carry materials which would ordinarily leak out of wooden boxes. Loose materials which must be transported about the mines in cars can be placed in the boxes and kept secure against pilfering and leakage.

Olyphant, Pa.

J. K. W.

Copper-Plated Carbon Brushes Usually Not Necessary

When pigtails were used on motor brushes it was considered necessary to copper plate the carbon to provide a good electrical contact for the shunt connection. With the present design of locomotive motor brush holder having a heavy braided copper shunt from contact tip to the box, shunted carbons have been discontinued, so that plating is unnecessary; in fact, it is objectionable on the better grades of carbon, as it tends to peel off in service and bind the carbon in the box.

Welded Sign Box
for Mine

This sign is made by welding sheet-iron panels together and cutting the letters on the front or rear. Lamps placed inside the box cannot be stolen when a padlock is snapped on the cover.

Production And the Market

Dwindling Stockpiles Presage Renewed Activity In Bituminous-Coal Market

Customers long absent from the soft-coal marts are due to reappear soon. Those consumers who accumulated swollen reserves of coal in anticipation of a strike when the old union agreement expired and who have been relying on their stocks most of the time since are at last nearing the bottom of their coal piles. As a result, while the coal producer's face is not exactly wreathed in smiles, he is beginning to perk up and take a renewed interest. The long-awaited decision on rail rates to the Northwest has helped to clarify the atmosphere somewhat, though the usual howl of protest is coming from the interests on the losing side.

Sound Basis for Industrial Revival

While there is as yet no noticeable recession from the policy of curtailment that has prevailed for some time in most industrial lines, due in some cases to overproduction in the latter part of last year and the early part of this year, with consequent heavy carry-over, basic conditions are pronounced as sound by industrial leaders, who give assurances that an industrial revival may be expected by autumn. The usual cautious policy of business during a presidential election year has hit the coal industry particularly hard, but the passage and signing of the tax-reduction bill, as well as the adjournment of Congress, undoubtedly will prove of benefit in hastening the expected upturn. Meanwhile the clearing out of surplus stocks in all lines will insure the basis for a lasting revival of industry.

Coal Age Index of spot prices of bituminous coal advanced 1 point during the last week, standing at 170 on June 9, the corresponding price being \$2.06. This compares with \$2.04 on June 2.

Activity has fallen off at Hampton Roads, dumpings of coal for all accounts during the week ended amounting to 318,918 net tons, compared with 371,564 tons

during the preceding week. Coal dumped at Lake Erie ports during the week ended June 7, according to the Ore & Coal Exchange, was as follows: Cargo, 619,115 net tons; fuel, 37,198 tons. The totals for the previous week were 625,440 tons of cargo coal and 39,640 tons of fuel coal.

Bituminous-coal production took a tumble by reason of the holiday during the week ended May 31, when according to the Geological Survey, 6,699,000 net tons was produced, a falling off of 464,000 tons from the output of the week ended May 24. Anthracite output

likewise declined sharply, for the same reasons, to 1,294,000 net tons, compared with 1,850,000 tons during the week before.

The lull foreshadowed in the anthracite market is now an actuality, demand having slackened and movement tapering off correspondingly. Circular prices were advanced June 1 by the companies and most of the large independents, the increases, which were not uniform, ranging from 10c. to 20c. on the sizes above pea, 10c. being the predominant rate of advance. Advance bookings by the large companies are taken to indicate a marked renewal of activity in the autumn.

(a) Revised from last report. (b) Subject to revision. (c) Minus one day's production to equalize number of days in the two years.

Midwest Disappointed

June 1 came and went without stirring up the least bit of coal business. This disappointed a number of coal gentry in the Chicago region who had been looking forward to a slight improvement of industrial business even if there was no domestic demand—as there is not. Stagnation is so great that even Illinois and Indiana screenings have receded a trifle from the \$2 price, in spite of the small supply. A scattering few industrial and utility contracts were made after June 1, but practically every plant is either living on its storage or buying day-to-day coal at the abnormally low market. Railroad deliveries are about all there is. Few if any new railroad contracts have been made, but price agreements have been made by most midwestern lines and coal is being ordered on that basis.

Good smokeless mine run continues to reach the Chicago territory in a thin stream at a quoted price of \$2 with shadings here and there. This meets about all the domestic demand there is. Anthracite is slow indeed, in spite of definite assurance that prices are going to be nudged upward the first of every month the rest of the summer.

The southern Illinois field is still quiet, with very little doing and no great demand for any size. Screenings, which were in good demand recently, have eased up and some

mines are carrying no bills on all steam sizes. The strip mines seem to be making considerable headway and strip-mine coal is being sold as low as \$1.75 for mine run and crushed screenings have been sold as low as \$1.45. In the Standard district all sizes are unbilled and running time is light.

St. Louis business continues unusually quiet. The dealers are doing a little business for current needs on account of cold, rainy weather and here and there a little storage is being put in, but it is not a factor.

Price Tendency Higher in Kentucky Fields

Conditions over the week are unchanged from those of the weeks past, with the exception that eastern Kentucky egg is firmer as a result of some demand developing for 2-in. lump. There is a tendency in all state fields toward higher prices, but without much result. Some of the producers of high-grade Harlan byproduct coal in southeastern Kentucky are offering 2-in. nut and slack at \$1 a ton; straight mine run, \$1.50 @ \$1.65, 2 x 4 egg, \$2; and 4-in. block, \$2.10 to the jobbing trade, while some screenings can be had as low as 80 to 90 cents a ton.

Lake movement is beginning to help the Hazard field slightly. However, there are many mines in all fields of

Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines

	1924				1923
	June 9	June 2	May 26	June 11	
Index	170	169	167	215	
Weighted average price	\$2.06	\$2.04	\$2.02	\$2.60	

This diagram shows the relative, not the actual prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913-1918," published by the Geological Survey and the War Industries Board.

the state that are either down or badly in need of business. Some western Kentucky mines are offering solid-shot coal on a mine-run basis at \$1.35 a ton to the jobbing trade during the first half of June, and slightly higher prices on machine cut from underground mines. Some stripper coal is offered as low as \$1.25. Quotations of jobbers range from \$1.50 to \$1.90 but can be shaded somewhat. It is reported that some houses that have been quoting 6-in. block at \$2@2.25 are asking \$2.25@2.50, and there is an effort to get 15c. or 20c. a ton on egg and nut sizes, along with lump. Screenings are steady at around \$1.40@1.60, but in small supply. The strike situation in western Kentucky is unchanged.

Production continues to gain a little in the high-volatile fields of southern West Virginia. In the northern part of the state the output is not equal to more than half of the corresponding period of 1923 but in southern West Virginia production is averaging about 50 per cent and in some fields as high as 75 per cent. There has been no further gain in smokeless output.

Prices Off In Northwest

Shipments from the docks at Duluth-Superior last month totaled 13,728 cars, of which the majority came from Duluth, owing to the fact that docks were anxious to move Duluth coal because of the assessment on May 1. The shipments are some 2,000 cars less than in April, and it is asserted that the majority of the cars moved were railroad coal, so that little commercial coal went out.

Business is at the lowest ebb. Two price changes have taken place. Youghiogheny and splint run of pile have been cut to \$5, and Youghiogheny and Hocking screenings

are down 25c. to \$3.75. Docks report this an adjustment, but when it is considered that many are reported cutting 50c. to \$1 on contracts it looks very much as if the market is less than the list.

The movement of coal to the Head-of-the-Lakes continues. Twenty-four cargoes were received during the week, of which three were hard coal and the cargoes en route are reported as five with one of hard. Figures of receipts to May 27 show that nearly 1,000,000 tons have been received this year.

The Milwaukee market is still depressed and the prospect is that it will continue so until business in industrial circles picks up. Jobbers are hopeful for better things later in June, however. Prices continue unchanged with the exception of anthracite, which was given the usual 10c. monthly advance as is the rule during the summer period. Egg is now \$16.10, stove \$16.50, nut \$16.35, pea \$14. Receipts of coal by lake at Milwaukee up to and including May 31 were 131,908 tons of anthracite and 301,049 tons of soft coal.

The effect of the new rail rates to the Northwest, which, if they go into effect on schedule time, Aug. 21, will add 8 to 28c. to the cost of shipping in Illinois coal, is yet to be determined. There are many guesses at the situation. However, the docks stand to win, and it is expected that a heavier shipment to the docks will soon begin. It is reported a fight is to be made by rail shippers to get the increase into the Twin Cities to be set at less than 28c. This may delay the effect of the I.C.C. decision all year or longer.

Western Trade Is Spotty

Little summer storage is reported by operators of the Southwest. A few mines closed April 1 have been reopened. The Central Coal & Coke Co. recently signed a contract with the Frisco for Kansas coal that opened a couple of its shaft mines. The Missouri Pacific a few weeks earlier had contracted with the Western. Except for a limited stable industrial demand, the only other activity in Kansas mines is the result of a pre-season demand for threshing coal. A few Arkansas mines have been reopened in anticipation of a summer demand inspired by substantial freight reductions, but the demand itself has not yet materialized.

Prices are: Kansas lump, \$4.50; nut, \$4; mine run, \$3.50; screenings, \$2.50. Arkansas semi-anthracite lump, \$5.50 @ \$6; mine run, \$3.50; screenings, \$2. Henrietta (Okla.) lump, \$5.50; nut, \$3.75; mine run, \$3.50; screenings, \$2.50.

Dealers and buyers remain indifferent to Colorado coal despite the fact that operators announced another small advance in prices June 1. Colorado mines worked on an average of 22 hours last week and reports from the operators show 37 per cent time lost because of no market.

Utah operators are moving very little coal. Industries other than smelters are taking next to nothing. Mines are working two days a week with difficulty. Retailers have been doing a little better during the past week as a result of a cold snap, but the trade is not stocking up. Retailers demand price stability.

Hopeful Signs at Cincinnati

Lake buyers are still marking time at Cincinnati showing little or no disposition to rush the market with orders. The boost to \$3.75 a ton on smokeless, egg and lump, caught a number of jobbers and retailers unprepared for the change of pace in these lines. There has not been quite enough to go around and June orders have been enough to put the books ahead for a while so that local wholesalers have not been able to "pass on" the usual tonnage that boasted of being free. Nut too has maintained its strength and while \$2.50 is the circular in more cases than one it takes \$3 to get the standard Pocahontas. In the bituminous market a steady and better undertone is noted, prices holding their own. Operators in southeastern Kentucky are holding their prepared coals at 25c. a ton higher than the West Virginians, asserting that they want to make at least the cost of production.

A slightly better demand for steam grades is reported in Columbus. Buying by large consumers is more brisk, as a result of the depletion of reserves. Public Utilities and railroads are taking the larger part of the tonnage, but there is a fair business with iron and steel plants. Price for screenings are slightly stronger while mine-run quotations are unchanged from the previous week. There is no as much free coal available, as many of the larger operations have been closed. Domestic trade shows signs o

revival, though the volume is still low. Pocahontas smokeless grades and splints are the principal varieties desired. Kentucky grades also are in good demand. A large part of the tonnage being loaded at lower lake ports is from West Virginia and Kentucky mines. Little lake contracting is reported.

Extreme pessimism is the keynote of the Cleveland market. Industrial activity has slackened considerably and there is a dearth of inquiries for fuel. The only change in the market situation is a slight stiffening in slack and nut and slack of 5 to 10c. per ton, and this is explained as being simply a fluctuation arising from a rather transitory condition when demand for a particular grade strengthens for a day or so. It is estimated that the stocks laid by prior to April 1 will not be depleted until after the end of the month, and this offers some ray of hope.

The coal situation at Buffalo has not changed much. Consumption is pretty good, but a slowing up of industries of late and too many shippers and salesmen have made rough sledding.

General Depression Grips New England

In New England the market now is much the same as during mid-summer in the old days, except that buyers today have no prospect of any spurt in business in September and that even on contracts deliveries are not being accepted with usual regularity. While stocks are not unduly large, the curtailment in manufacturing is so general that reserves are not depleted as in normal times. Railroad traffic is much lighter, and all the public-service companies are felling the depression in all the industries.

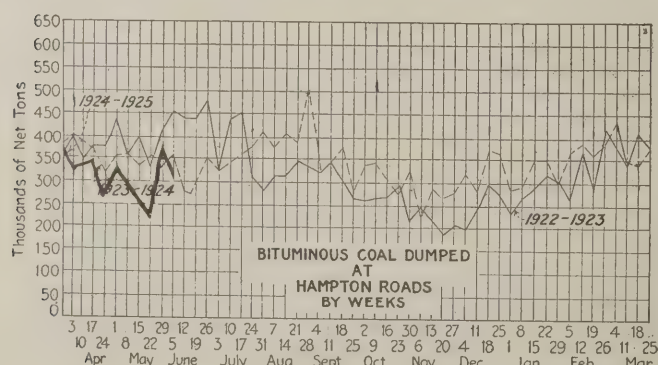

At Hampton Roads the accumulations of a fortnight ago have been somewhat reduced, the tonnage on hand at the three ports amounting now to little more than 100,000. Output is again being restricted rather rigidly, but it will take several weeks more of the same close-hauled policy to warrant any material increase in price. Reports show that small tonnages are changing hands on about the same price level that has prevailed for several weeks, namely, \$4.35@\$4.50 per gross ton f.o.b. vessel for No. 1 Navy Standard grade. No. 2 coals are to be had at prices down to \$4.10, and in some cases as low as \$4. The net return to some of the higher cost operations must be discouraging.

For distribution inland there is also only scattering inquiry. The nominal quotation for highest grade Pocahontas and New River still is \$5.50 per gross ton on cars, but occasionally there are signs of lower prices when buyers have the appearance of being interested.

All-rail from central Pennsylvania there is practically no change. A few cars of special sizes filtered through to tidewater territory, but a large proportion of the coal passing the Hudson River gateways is confined to destinations not much east of the Connecticut River.

Trade at Low Level in Eastern Markets

Demand continues slow at New York notwithstanding the efforts of various agencies to induce stocking. The feeling is growing, however, that business will be better soon. Stockpiles are shrinking and indications point to a restocking program soon. That coal continues to move at low prices is indicated in tenders received by the U. S. Shipping Board at New York on June 5 for furnishing and delivering alongside vessels that harbor on June 8, 3,300 gross tons of soft coal of a minimum of 14,500 B.t.u., the quotations ranging from \$5.04 to \$5.43 per ton. In some quarters a better inquiry is reported, but no immediate betterment is

expected until an improvement is noted in general business conditions. Receipts at tidewater during the week showed a wide range, going above 1,800 cars at times. There was no tendency, however, to cut prices.

Dullness persists at Philadelphia, though a number of shippers note a slight betterment in business. The hoped for improvement depends upon the industrial situation and there is no sign of betterment. The railroads show the effects of the slump in that the sidings hereabouts are choked up with empty cars. The fuel demands of the roads also are considerably lower, although they are taking a fair tonnage for stock. The spot price market shows no change and the tide market is nil.

The uncertain state of the export coal market at Baltimore is shown in the fact that not a ship cleared with coal for foreign delivery during the first week in June. The trade as a whole in fact is flat. The depletion of stocks through present demand exceeding production is now such a patent condition that both large consumers and coal men themselves are beginning to take sharper notice of a state of affairs that must develop before many weeks are past.

No coal is being bought at Birmingham except as actually needed for current use, and there appears to be no signs of any immediate revival. Transportation conditions are such that the railroads are taking minimum deliveries and shipments against commercial contracts likewise are rather light.

Anthracite Trade Slackens Further

Demand for independent anthracite has slackened further at New York and buyers hesitate before paying more than the larger company circular for domestic sizes. Egg and chestnut are moving considerably slower than stove, but producers are not experiencing any trouble in keeping down accumulations. Interest last week centered in the change in prices of company coals and of some of the larger independent producers. The increases were not at all uniform, ranging from 10c. to 20c. on broken, egg, stove and chestnut. There were no changes in steam prices. Receipts at tidewater were reduced somewhat by the cut in production due to the holiday of the previous week as well as petty labor troubles, at some of the mines. Notwithstanding the present lull in demand an active fall is looked for, the large companies being well booked up for several weeks ahead.

With the arrival of moderately warm weather at Philadelphia the slowing down has become more of an actuality with the retailers. As yet the operators have not felt much of it, as the retail men hesitate to hold orders for fear of embarrassing themselves when coal becomes scarcer. Prices at the mines went up June 1, the company shippers adding the usual 10c. to the sizes above pea, prices remaining the same under that size. Some of the independents made increases of as much as 20c. The leading retailers have added 25c. a ton to the retail prices. The chief demand is for stove, nut is accumulating faster in the yards than it is going out, while pea has shown signs of being a drug with the larger operators and they are putting some of it into storage.

Foreign Market

And Export News

British Coal Market Unsettled; Output Declines Slightly

The Welsh coal market is very unsettled and in a generally unsatisfactory condition. The recent slight improvement has not been maintained, the absence of support having caused the market to relapse. The demand is slightly better though not up to the late winter standard. The operators consider present prices insufficient to meet working costs, so that the closing of more pits is regarded as inevitable. Shipments at the docks are much below normal. The Welsh miners are said to be dissatisfied with the new agreement which has been provisionally accepted by their leaders. Exports have fallen off sharply and prices are in favor of buyers.

The Newcastle market continues to be slack with prices low. In spite of the Ruhr lockout German coal is competing with British in the Baltic and the Mediterranean, especially in Italy. The Swedish state railways are asking tenders for 227,000 tons of steams for shipment from June to September. Operators have cabled tenders for 50,000 tons of steams for the Finnish state railways.

Output of coal at British coal mines during the week ended May 24, a cable to *Coal Age* states, was 5,436,000 tons, according to the official reports. This compares with 5,659,000 tons produced during the week ended May 17.

Business Slightly Better and Tone Firmer at Hampton Roads

Business at Hampton Roads shows slight improvement, with demand somewhat increased and supplies at tide-water increasing. Prices are holding firm, with a tendency upward, although no immediate material change is forecast.

Substantial movement to South America on contracts with the Brazilian government has been one of the

features of the trade. Coastwise movement shows a slight increase and bunker trade holds its own, with a lull in general shipping. The trade is resting on the oars, so to speak, and expects continued mild activity during the coming month.

The tone of the market is slightly firmer than the previous week, though the outlook has not materially changed.

French Market Reacts Mildly to Ruhr Mine Strike

Very little change is observable in the French coal market except for a slackening of orders for British coals and a diminution of shipments from the Ruhr, due to the rise of sterling on the one hand and the strike in the Ruhr mines on the other. The French collieries note an improvement in the situation as a consequence. Prices, of course, reflect an increasing spread between British and French coals as sterling rises. Belgian coals continue higher than the French, despite the rebates applied.

Deliveries of reparation coal to France by Germany during the first three months of 1924 were as follows in metric tons: January, 282,019 tons of coal and 67,329 tons of lignite; February, 307,754 tons of coal and 74,729 tons of lignite; March, 318,721 tons of coal and 17,847 tons of lignite.

Coke deliveries to the O.R.C.A. during the first three weeks of May averaged 9,250 tons a day. The strike in the Ruhr did not affect shipments to the extent that had been expected.

The O.R.C.A. was definitively constituted on May 16 in the form of a joint stock company with the same statutes as the late S.C.O.F. Mr. de Wendel is president of the organization and Colonel Pineau is the director. There are twenty-eight adherents now, and the Société Normande de Métallurgie is still to be heard from.

News Items From Field and Trade

ILLINOIS

Drillers in the vicinity of Fairfield, while drilling for oil and gas, struck a 9-ft. seam of coal at a depth of 1,050 ft. This is deeper than any coal operated in Illinois. Just before striking the seam they drilled through a 5-ft. shell of very hard black lime and rock. The coal is of good quality and similar somewhat to that recently struck by drillers near Wayne City.

Robert M. Medill of Springfield, former State Director of Mines and Minerals of Illinois, and Attorney Lawrence Glenn, of Murphysboro, are operating the Hallidayboro mine of the Jackson Coal Co. as receivers.

INDIANA

The McDonald Coal Co. of Linton, has filed papers showing the final dissolution of the corporation.

The Big Four R.R. is building a spur from Somerville to Francisco, near Princeton, to connect the new Somerville mines with the main line.

Contracts for coal for county institutions have been awarded at Indianapolis to the Central States Coal Co. for Indiana No. 4 mine run at \$3.25, to the Rader Coal Co. at \$3.23, and the Dudley Coal Co. at \$3.68.

U. S. Lesh, State Attorney General, has submitted an opinion that the state must refund \$5,817 to Sullivan County for taxes on coal land which were paid back to farmers of that county under a Supreme Court decision. Coal was found under the lands, assessed for taxation and the coal companies leasing the land were taxed on the coal. Farmers who leased the land filed claims for refund of taxes, for which they said they had been assessed on the coal deposits.

A petition asking the appointment of a receiver for the Eureka Coal Co., Terre Haute, operating the Dixie B mine, in Vigo County, has been filed by John T. Aitken and Robert Aitken, stockholders, who allege mismanagement of the company by present officials and charge the property is being permitted to depreciate. The petition says William E. Eppert is president of the company and Charles H. McCalla the secretary. The company was incorporated in 1918 with a capital stock of \$500,000 and the petition charges the property now is worth about \$400,000. The mine has a capacity of about 1,000 tons a day.

KANSAS

The Central Coal and Coke Co. has resumed operations at two of its mines near Pittsburg. Reopening of the mines, closed since April 1, will furnish employment for 725 men and will provide a production of more than 2,000 tons a day.

Kansas miners have voted three to one for a special assessment to provide relief for members who are out of work. Announcement of the results of the referendum election was made at the district offices of the United Mine Workers.

KENTUCKY

The John P. Gorman Coal & Mine Co., Lexington, has taken over the property of the Elk Creek Coal Co. and will operate it as mine No. 2.

The Elkhorn Gas Coal Co., Pikeville, has changed its name to the Barrowman Coal Corporation and has increased its capital from \$50,000 to \$200,000 in amended articles filed at Frankfort.

A fair amount of coal is coming into Louisville from the Kentucky River mines by water of late. The two boats J. F. Butts and Margaret brought three barges each into the local port last week from mines near Beattyville, on the Kentucky River, picked up empty barges and made return trips.

The Louisville & Nashville R.R. on May 31 issued a statement at Middlesboro, denying rumors to the effect that there had been a disagreement between the Louisville & Nashville and the Southern Ry. and that the Southern was figuring on retiring from handling coal out of the Middlesboro territory because of differences over leased use of a certain section of railroad controlled by the L. & N. The company stated that the rumors were unfounded as the roads are co-operating nicely, and the lease arrangement has been satisfactory to all parties.

The Kentucky Utilities Co., which furnishes most of the mine power used in southeastern Kentucky and on the Virginia border, has bought all of the stock of the Old Dominion Power Co., of Norton, Va., announcement having been made by C. H. Dickey, manager on advice from New York, that the deal had been closed on May 31. The stock was held by the Wise Coal & Coke Co., Norton; New York Mining & Mfg. Co., New York, and J. L. Kimmerer. The property was assessed at \$280,000, but valued at \$1,000,000.

MICHIGAN

The Ford Motor Co. is shipping soft coal to its plant at Iron Mountain by way of Menominee. The transfer of the coal from vessel to cars is made over the dock of the West Coal Co. The steamers engaged in the trade belong to the Ford company.

MINNESOTA

That old-time firm, the Holmes & Hallowell Coal Co., St. Paul and Minneapolis, has been dissolved, the Holmes Coal Co. succeeding to the St. Paul end and the Hallowell Coal Co. to the Minneapolis part. The latter has moved its office from 158th Street South, to 214 Plymouth Building.

The decision of the I.C.C. on the Illinois rate case has seemed like a farce to coal men at Duluth. The rate from Illinois mines to the Winona and Mankato districts was increased 8 to 13c., and 28c. to the Twin Cities. This is farcical when it is considered that the differential which now exists on Twin Cities is \$1.20. On top of this the I.C.C. cut the rate of Illinois coal to Duluth 24c. on soft and 36c. on hard.

NEW YORK

W. A. Marshall & Co., Inc., New York City, announces the transfer of Edward H. Nicoll to the company's Philadelphia office, where he will be in charge of that territory. Frank R. Stuart has been transferred from the Johnstown office to the New York office in charge of line salesmen.

OHIO

The Southern Ohio Coal Exchange reported for the week a total production of 60,811 tons out of a full-time capacity of 646,583, from 441 mines reporting.

A called meeting of the Cincinnati Coal Exchange was held on June 6 at which the "Program of Progress" for the city was explained by Monte Goble, of the Fifth-Third National Bank. The coal men promised to aid to boost things along. The exchange is the largest subsidiary of the Chamber of Commerce.

Sealed proposals were received June 4 by the city Board of Purchase of Columbus for approximately 700 tons of 2-in. screened Hocking Valley coal to be delivered in amounts specified by the chief of the fire department to the various engine houses of the city. The

Franklin Builders Supply & Coal Co. was low with a bid of \$4.09. The Lewis & Noon Coal Co. was second low with a bid of \$4.30 and the Homer C. Gill Co. was a close third with a bid of \$4.36.

Heroism of Bernard Donahue, aged 40, of Belmont County, Ohio, at the time of the Benwood disaster in April, when 119 men lost their lives, has won executive clemency for him following conviction upon a charge of manslaughter. At the time of the Benwood disaster, Donahue, having a wide knowledge was called upon to lead a rescue crew. Disregarding the risk, Donahue made many trips into the mine until the rescue work was completed. He was sentenced to the penitentiary for killing an Italian girl while driving in an intoxicated condition. Governor Donahey granted a pardon upon Donahue's promise to abstain forever from the use of intoxicating liquors.

PENNSYLVANIA

A number of collieries in the Pottsville region will be given more efficient electric power with the completion of the East Penn Electric Co. power house at Pine Grove. The plant cost \$3,000,000.

Modern mining appliances have made possible the reopening of the Silver Brook workings. The workings were abandoned almost half a century ago, but it is possible that the success which has attended the new operation will result in the reopening of many more older workings in the region.

State foresters in the anthracite field express the opinion that the danger of forest fires is about over, due to the severe drenching given the earth by rains during May. More than five inches of rain soaked the trees and bushes and penetrated the fallen leaves during the month.

Dean Holbrook, of the mining engineering school of State College, was

the speaker at the recent graduation exercises of the Hazleton Mining Institute. Arthur Sandrock, a member of the Lehigh Valley engineering corps, took part in the program. Walter Fahringer, of Audenried, superintendent of the Lehigh & Wilkes-Barre Coal Co., presided.

The Bixler Coal & Coke Co., Pittsburgh, has been appointed Western Sales Agents for the Piedmont & George's Creek Coal Co.'s Washington No. 5 Mine and the R. J. Ross Coal Mines, Inc. These mines are located in the George's Creek district, in Maryland, producing a hard structure smokeless coal for domestic purposes.

By the terms of a general settlement of the coal land taxes of the Lehigh Valley Coal Co., reached and approved by Judge Bechtel, May 27, at Pottsville, the company is required to pay taxes on an assessment of \$12,000,000 hereafter instead of on \$5,000,000. This is a compromise, as the assessment originally made two years ago would have required the company to pay taxes on a valuation of \$24,000,000.

The University of Pittsburgh senior class in mining has returned from its underground surveying trip, which was in charge of Robert M. Black, professor of mining. The party spent two weeks at the limestone mine of the American Lime & Stone Co. at Bellefonte, which was selected for the survey because of the large opportunity it offers for problems.

It is reported that the mine fire at the Potts colliery, near Minersville, is raging afresh.

At a meeting of the Luzerne County judges as a court *en banc*, members of the Miners' Examining Board for the First Anthracite District, comprising Luzerne County, were reappointed and two men were named examiners in place of two who had died. George Kolar, of Freeland, was appointed to succeed Patrick McGuire, deceased, of Hazleton and James Owens, of Ed-

wardsville, was appointed in place of John H. Evans, deceased. The following were reappointed: Gustave Ulberich, of Wilkes-Barre; Michael H. Quinnan, of Pittston; Harry Cook, of Nanticoke; James F. Gildea, of Plains; John B. Thomas, of Dorrnceton; Alexander Patterson, of Hazleton, and James McGlynn, of Jeansville.

The following changes among colliery superintendents, effective at once, have been announced by the Pennsylvania Coal Co. George Huntley, superintendent at No. 9 colliery, is transferred to Butler colliery; James Johnson, superintendent at the Butler colliery, is transferred to Central colliery, and P. H. O'Brien, superintendent at the Central colliery, is transferred to the No. 9 colliery.

The Hazleton Machinery & Supply Co. has installed a heating plant in the new steel and concrete breaker of the Hazle Brook Coal Co. at Raven Run. This electrified plant will keep up production during the winter with the same speed as in summer, as the heating plant will prevent all difficulty arising from frozen coal. Another innovation will be the delivery of mine cars direct to the top of the breaker instead of at the base, the builders having taken advantage of the contour of the land.

A sale involving approximately \$140,000 was completed in Uniontown when 70 acres of Connellsville coking coal in German and Georges townships acquired from Samuel Stern by the Crawford Coal & Coke Co., of Connellsville. The property includes the old Break-iron tract in German township and the David tract in Georges township, adjoining the present holdings of the Crawford company. It also adjoins the Shoaf plant of the H. C. Frick Coke Co. J. R. Davidson, of Connellsville, is president; J. Q. Adams, of Uniontown, is vice-president, and Gaetano Corrado, of Connellsville, is treasurer and general manager of the Crawford Coal & Coke Co. F. T. Adams is a director.

WASHINGTON, D. C.

L. A. Snead Co., shippers of coal and coke announce the removal of their offices to 1117-25 Investment Building.

WASHINGTON

Examinations will be conducted by the State Mine Examining Board at the State Capitol, Olympia, on Aug. 4 and 5, for first and second class mining certificates. Those desiring to take these examinations may procure application blanks at the mine office in each of the camps. Applications must be filed with Fred J. Dibble, director of licenses, Olympia, at least 10 days before the date of the examination.

WEST VIRGINIA

The mine of the Kingston Pocahontas Coal Co. on Paint Creek has been reopened and is rapidly increasing production. Once the output reaches nor-

New Unloading Plant on Ohio River at Cincinnati

Island Creek Coal Co.'s steel elevators for the transfer of coal from barges to hoppers. The hoppers are of steel and concrete, equipped with shaker step screens for rescreening and preparing lump and egg coal for domestic use. The plant was constructed by Heyl & Patterson, of Pittsburgh, and can unload 400 tons per hour. The bucket has a capacity of 5 tons. Two belt conveyors carry the coal from the screening house to storage. Wagon or railway-car loading is possible from the chutes and hoppers.

mal, approximately 175 men will be given regular employment.

Since the signing of an agreement between the Bertha-Consumers Co. and the United Mine Workers the Bertha mine at Maiesville has resumed operations. This makes 11 mines operating in Scott's Run territory with an average production of about 900 cars a week.

Operations have been resumed at the Dartmoor mine of the Davis Coal & Coke Co. in the Barbour County field. This is one of the larger mines of the company which has not been in operation for a month or more. As a result of resumption several hundred men will be given employment again.

Walter H. Cunningham, secretary of the West Virginia Coal Association and also a well known mining engineer, has just prepared a map of southern West Virginia, showing the locations of mining districts, plants and creeks and also the separate and aggregate tonnage of the districts. Not only does the map cover southern West Virginia districts but also Tazewell County, Virginia, and the Martin and Pike County, Ky., mines.

The Virginian Ry.'s new electrically operated pier at Sewalls Point when completed will be the largest single coal-dumping pier in the world. It will be approximately 1,074 ft. long, 86 ft. wide and 74½ ft. above mean low water. The pier is to cost approximately \$3,250,000 and will have a dumping capacity of 3,600 tons per hour. The road also is making extensive improvements on the western end by electrification of the 133 miles between Mullens, W. Va., and Roanoke, Va.

Lyda Davis, aged 27, a coal miner, and Guy Vincent, a farmer of Shinnston, must serve six years in the West Virginia penitentiary for the part they played in burning the tippie of the Ohio-Balkan Coal Co., at Dola on the night of March 17. Davis and Vincent were tried and convicted in the criminal court of Harrison County. Thomas Holt and Harry Leasure are now in the Harrison County jail awaiting trial for complicity for the same offence. It was alleged during the trial of Davis that he helped set fire to the tippie while in an intoxicated condition after meeting Holt and Leasure.

According to an official of subdistrict 4 of District 17, United Mine Workers, three suits have been instituted in the Circuit Court of Monongalia County against the Brady-Warner Coal Corporation, each for \$10,000 damages. The actions have been brought because of forcible entry of the company's agents into the homes of former employees, and forcible eviction of the plaintiffs and their families and removal of the household goods. Under a recent ruling of the West Virginia Supreme Court, coal companies have the right to regain possession of company houses when employment ceases, voluntarily or otherwise, after due notice, and without committing any breach of the peace.

UTAH

E. F. Taylor, of the state land office, will auction 120 acres of coal lands in Carbon County at an early date. The property includes lots land 2 southeast quarter of the northwest quarter of section 19, township 13 south and range 8 east.

J. J. Bourquin, engineer of the U. S. Bureau of Mines, has been appointed supervisor of operations of the Federal Coal Land Leasing act under the general direction of B. W. Dyer, district engineer of the Bureau of Mines and chief state mine inspector. His services, it is stated, will include the duties

Michael Gallagher

General manager of the M. A. Hanna Co., Cleveland, Ohio, and just elected a vice-president of the National Coal Association at the Cincinnati meeting.

of looking after the government's leasing operations and assisting in the work of state mine inspection. Mr. Bourquin comes from Pittsburgh, Pa.

Utah coal-mine operators will join with California retail coal dealers in a newspaper campaign to educate the California public to the advantages of using coal as a fuel in the home. Associated with the Utah operators, it is stated, will be mine owners in New Mexico and Wyoming. It is believed that this campaign will spread until it develops into a national movement. The campaign is the result of a conference held in Salt Lake City.

CANADA

To increase the available output of domestic coke, the British Empire Steel Corporation will soon erect a coke crusher at its plant at Sydney, N. S., capable of turning out about 20 tons an hour of coke of the proper size for domestic use.

The coal commission to investigate conditions in connection with the coal industry of the Province of Alberta has not yet been appointed. It is stated that it will not be named until definite information is received with regard to the transference of the natural resources of the province from the jurisdiction of the Dominion Government.

The commission is expected to deal with matters such as supplies of coal, mining methods and all questions pertaining to labor conditions.

Association Activities

The Fayette-Greene Coal Producers Association held a "Shop Talk" dinner meeting at the Summit Hotel, at the Summit, near Uniontown, Pa., at six o'clock Wednesday evening, June 11. The principal talk of the evening was on rockdusting by Captain Edward Steidle, of Carnegie Institute of Technology. Mechanical loading also was discussed. The discussion on rock dusting was under the leadership of Mr. William Z. Price, assistant superintendent of the Buckeye Coal Co. A large number of superintendents and mine foremen were present.

Industrial Notes

The Columbus Mining Co., of Allais, Ky., it is reported, is preparing to spend \$50,000 on improvements.

The Chicago office of the Hazard Mfg. Co., manufacturers of iron, steel and galvanized wire rope, removed May 1 from 552 West Adams St. to 32 South Clinton St.

Colwell & McMullin, New England representatives of the Conveyors Corporation of America, Chicago, will on May 1 locate in their new offices in the Park Square Building, Boston, Mass.

The Newark Wire Cloth Co. is now established in its new plant at 351-365 Verona Ave., Newark, N. J. The new building is 100 x 310 ft., covering approximately three-quarters of an acre in floor area.

The Cleaton Co., (Canada), Ltd., eastern Canadian representative of the Conveyors Corporation of America, Chicago, has moved to its new office at 1070 Bleury Street, Montreal, Quebec. R. E. Cleaton is president and N. Bannatyne, chief engineer of the organization.

W. A. Cather, formerly in charge of advertising and sales promotion for the Worthington Pump & Machinery Corporation, has been made sales manager of the Barrett Haentjens Co., makers of centrifugal pumps. He will be located at the company's plant, in Hazleton, Pa.

The Tompkins Fuel Co., with mines at Cedar Grove, W. Va., on the New York Central Lines, is building a new steel and frame tippie for its No. 5 mine. The tippie will be equipped with shaker screens, loading booms and picking table. The company expects to install at this same mine in the near future a new substation, probably motor-generator set, haulage motors and shortwall mining machines. The directors of the company, recently elected, are Harold P. Tompkins, president; Clyde B. Johnson, secretary; Roger W. Tompkins, general superintendent; Wm. G. Conley and Grant E. Tompkins.

Traffic News

Trunk Line Hearings on Proposed Advance in Rates

The Coal and Coke Committee, Trunk Line territory, will hold a hearing at 11 a.m. (daylight saving time), June 26, in room 401, 143 Liberty St., New York City, on a proposal to advance rates on bituminous coal from mines on the Buffalo, Rochester & Pittsburgh Ry. and the New York Central R.R. in the Clearfield district to stations of the Bush Terminal R.R. in Brooklyn, N. Y. The present rates is \$3.44, which it is proposed to increase to \$3.47.

The committee also will hold a hearing at 11.30 a.m. on the same day and at the same place on a proposed advance of 1c. per gross ton on anthracite (pea and smaller sizes) from mines on the Delaware & Hudson Co., Delaware, Lackawanna & Western R.R., Erie R.R., Lehigh & New England R.R., Lehigh Valley R.R. and New York, Ontario & Western Ry. to points on the New York, Chicago & St. Louis R.R.; as follows: Saybrook, Ohio, to Cleveland, Ohio; Swanville, Pa., to Springfield, Pa.; New York Central R.R. (West); Saybrook, Ohio, to West Park, Ohio; Swanville, Pa., to Springfield, Pa.

Five Cent Cut in Coal Rates on Chesapeake & Ohio

A 5c. reduction in coal freight rates from the fields served by the Chesapeake & Ohio Ry. will become effective on June 28, it has been announced by W. P. Tingley, traffic manager of the Jobbers and Manufacturers Bureau of the Huntington Chamber of Commerce. Mr. Tingley has just received a copy of the new tariff giving the rates affected by the reduction, which is calculated to effect a big annual saving to large consumers of coal in Huntington and Kenova. Agitation for the reduction was first started by Mr. Tingley several months ago when he conducted negotiations with the C. & O. It became assured several weeks ago following a conference with the Norfolk & Western R.R., which sanctioned the proposed reduction.

To Resume W. Va. Intrastate Rate Hearing June 16

After holding hearings in Fairmont during the latter part of May, the West Virginia Public Service Commission adjourned the intrastate coal hearings to June 16, probably at Charleston. Testimony adduced at the Fairmont hearing was largely of a technical nature dealing with rates, schedules, grades, division of territory and other matters entering into rate making.

A year or more ago the Public Service Commission put into effect new rates on intrastate shipments of coal and other articles but instead of decreasing rates it allowed an increase. The rate question has been reopened at the instance of the Domestic Coke Corporation, which operates a byproduct plant on an extensive scale in

northern West Virginia. A protest has been filed against the increase granted on state coal shipments, which it is claimed places an additional burden on industries, a number of which are located in Fairmont.

Obituary

James McGregor, formerly chief inspector of mines for British Columbia, died in Victoria, B. C., May 28. When a boy he went to work in the coal mines of Nanaimo, B. C., advancing himself to the position of manager of No. 5 Southfield Mine, Chase River, Vancouver Island. Subsequently he was elected to the provincial legislature and eventually was made inspector of mines for one of the interior districts. He was in the civil service for some twenty-five years holding the position of chief inspector at the time of his superannuation a year ago.

New Companies

The Old Cato Mining Co. has been incorporated at Henryetta, Okla., with a capital of \$25,000. The incorporators are C. E. Downs and Ben Meyers of Los Angeles and Gus L. Smith of Henryetta.

The Paris Coal Basin Mining Co. has been incorporated in Fort Smith, Ark., with a capital stock of \$25,000, with Ben Stroupe, president, and will develop a 40-acre tract near Paris. It will build six miles of railroad.

State charters have been issued at Harrisburg, Pa., to the following coal companies: Shamokin Colliery Co., Wilkes-Barre; capital, \$250,000; incorporators, Nat D. Stevens, 800 East Main Street, Nanticoke, treasurer; E. M. Chapin, Brookline, Mass., and Bruce F. Payne, Wilkes-Barre. Marwood Coal Co., Coraopolis; capital, \$15,000; incorporators, Fred R. Knight, Coraopolis, treasurer; Amos Gething, Coraopolis, and G. H. Baumann, Imperial. Schenley Fuel & Supply Co.; capital, \$10,000; incorporators, Robert Buka, Oliver Building, Pittsburgh, treasurer; Wilbur O. Nelson, Pittsburgh, and Guy E. Kneeder, Greensburg. Calumet Coal Co., Pittsburgh; capital, \$5,000; incorporators, Oliver Evans, 1047 South Negley Avenue, Pittsburgh, treasurer; Henry O. Evans and J. Garfield Houston, Pittsburgh.

Coming Meetings

Illinois Mining Institute. Annual meeting, June 12-14 from St. Louis via boat down the river. Secretary, Martin Bolt, Springfield, Ill.

Midwest Retail Coal Association. St. Louis, Mo., June 17-18. Secretary F. A. Parker, St. Louis, Mo.

Colorado and New Mexico Operators' Association. Annual meeting June 18, Denver, Colo. Secretary, F. O. Sandstrom, Denver, Colo.

American Society for Testing Materials; annual meeting, Chalfonte Hotel, Atlantic City, N. J., June 23-27. Secretary, Edgar Marburg, University of Pennsylvania, Philadelphia, Pa.

American Institute of Electrical Engineers, annual convention, June 23-27, Edgewater Beach, Chicago, Ill. Secretary, F. L. Hutchinson, 29 West 39th St., New York City.

First International Management Congress, Prague, Czechoslovakia, July 21-24.

World Power Conference, Wembley, London, England, June 30-July 12. O. C. Merrill, Federal Power Commission, Washington, D. C.

Rocky Mountain Coal Mining Institute. Summer meeting, Aug. 7-9, Rock Springs, Wyo. Secretary, Benedict Shubart, 521 Boston Bldg., Denver, Colo.

New Equipment

Rerailer That Holds Itself Firmly in Position

Probably few petty mishaps occurring in or about the mines are more exasperating than derailments. While seldom serious in character these "accidents" often tie up the mine or a portion of it for more or less extended periods. When a trolley locomotive jumps the track an adequate ground connection is seldom afforded so that the machine may pull itself back onto the rails.

In order to render mishaps of this kind less serious the I. H. Edelblute Co., of Pittsburgh, Pa., has recently developed and placed on the market the rerailer a top and bottom view of which is shown in the accompanying illustration. These rerailers are built and used in pairs. Each has two broad wings that straddle the rail and guide the wheel onto it.

At its upper or narrow end this device is fitted with a cam that grips

Top and Bottom of Rerailer

Note that the underside of the device where it straddles the rail is curved longitudinally. Consequently as the wheel is guided onto the rail the rerailer rocks forward easing the wheel down with a maximum drop of $\frac{1}{4}$ inch.

the ball of the rail, and prevents the rerailer from being pushed in the direction of car or locomotive travel. The portion of the rerailer resting upon and supported by the rail is curved longitudinally so that when the weight of the wheel reaches a point above the rail it tilts the rerailer forward and downward easing the wheel down onto the rail with a maximum drop of $\frac{1}{4}$ in. After a locomotive, car or an entire trip has been retracted by this device a slight bump with a hammer or wooden block on its forward end releases the grip of the cam and allows the rerailer to be lifted from the rail.

This replacer has been designed especially for use in mines. It measures 17 $\frac{1}{2}$ in. long and is 15 in. wide across the board end. It can be placed between the wheels of any car or locomotive without interfering with brake rigging, sand pipes or other parts. It is not necessary to place the low or broad end of these replacers on a tie, neither need they be spiked in place as the cam grips the rail firmly holding the device securely in position. When replacing a locomotive the rerailer may

be set upon the rail in contact with a wheel giving a sufficiently good return circuit to permit the motor to climb the track under its own power.

These replacers are made of high-carbon, manganese-alloy steel and are specially annealed. They are amply strong to resist the rough usage that devices of this kind always receive and are guaranteed against breakage in service.

Self-Acting Mine Door

Among the interesting pieces of mine equipment shown in model form at the exposition in Cincinnati was the mine door recently placed on the market by the Ventilating Service Co. A photograph of the model there shown is presented in the accompanying illustration.

This door is double and is gravity operated. In its installation two posts are set, one upon either side of the heading or track. On these the doors are hinged, turning on roller bearings in such a manner that as they open they rise. Their own weight thus causes them to close after the trip has passed.

The part of the door extending across the track is hung by rollers from the upper portion of the frame in such manner that it may telescope with that part of the door on the opposite side of the hinge post. It is returned to normal position by the counter-weight plainly visible in the illustration. In this model the portion of the door outside the post is shown in skeleton form only. In any actual installation a plate will be fastened to the frame seen in the illustration. This fills up what might be termed the wing and prevents flow of air past the side of the door.

In operation a locomotive or trip traveling at any speed up to 15 miles per hour strikes the buffers on the inner edges of the doors, forcing them open and allowing the trip to pass, after which the doors return to their normal position by gravity. Now suppose that for any reason it is necessary to stop and reverse the travel of the trip before it has entirely passed through the doors. Stopping the trip

will not interfere with the door in the least. When it starts to back up, however, trouble might be encountered if the door were not built so that it can telescope and slide out of the way. This provision renders the door immune from injury by any movement that the trip can make while passing through in either direction.

This door is normally constructed to close against a water gage of 2 in. It can, however, be built to operate against any air pressure likely to be encountered in mine ventilation. One of these doors has been in successful use for more than six weeks, being subject meanwhile to the action of an eight ton locomotive. It is claimed by the builders that this device is simple, light, efficient, cheap and easy to install, and that its action is positive and sure, obviating the services of a trapper and relieving the locomotive crew from all responsibility for either opening or closing it. This in turn renders it impossible that a door of this kind will ever be left open to short-circuit the ventilating current.

Temperature Relays Heats in Same Ratio as Motor

A new thermal overload relay, designed to follow more closely the heating curve of the motor, has been developed by the General Electric Co. and will soon be on the market. This device is designed to afford better protection against overheating of the motor. It is made in both single and double pole types.

The relay contains two heating elements, one of which is a thermostatic strip controlling the motor circuit. The other element is enclosed in a metal block which, when heated, tends to increase the temperature of the thermostatic strip by conduction and radiation. The thermostatic strip corresponds to the copper in the motor, carrying the same or a proportional amount of current. The metal block contains the other heating element which corresponds to the iron in the motor, which has relatively high thermal capacity. The heating of both these elements combined thus corre-

Thermal Relay With Heating Characteristics Similar to Motor

This device consists of two elements, one functions to trip the motor circuit when the winding of the motor gets overheated and the other stops the motor when its frame gets too warm due to overload or single-phasing.

sponds closely to the actual heating in the motor, thus protecting it while in operation.

During conditions of ordinary loads on the motor, the heating of the thermostatic strip, due to the heat generated in itself and the heat absorbed from the metal block, is insufficient to produce enough deflection of the strip to stop the motor. In case of an overload which would damage the motor if permitted to continue, the heat absorbed by the thermostatic strip from the metal block is sufficient, when added to the heat generated in the thermostatic strip itself, to stop the motor. When the motor is subjected to an excessive overload, the heating effect of the thermostatic strip itself predominates and its deflection will effect the opening of the motor circuit within a short time.

Another feature of the relay is that it will inherently take into account the previous heating of the motor, by reason of the fact that the heat stored in the metal block is a measure of the heat stored in the motor.

Portable Welding Outfit With Many Taps

The Welding Metals Mfg. Co. of Cleveland, Ohio, has just placed on the market a portable electric welder enclosed in a substantial case and intended for production and maintenance work. It is now being made in capacities ranging from 50 to 150 amp. One outfit is made for use on 110-volt circuits, and another for 220-volt circuits. The resistance unit is arranged so that six different current taps can be taken from it. The 110-volt unit weighs 165 lb. and the 220-volt unit weighs 190 lb.

Model of Door That Is Opened by Locomotive and Closed by Gravity

Gravity closes this door when it has been opened by a passing trip. Should the trip stop and reverse its direction of travel before it has passed through the door no harm is done as the door plates may telescope within the frame. They are returned to their normal position by the counter-weights after the trip has gone by.

Wrong Kind of Publicity

COAL operators continue to believe that they can help the coal industry by defaming the union, but a knowledge of human nature will readily show how hopeless is the task. A man is responsible in public estimation for all the faults of his family. Suppose his boy acts discredibly, will denunciation of the boy restore the father's reputation? Not an iota. The better plan is to keep silent, hoping the public will forget.

The less said about Wallins Creek, Herrin and Cliftonville the better. The union was to blame, but the miners are part of the coal industry, and the public makes no fine distinctions between the employer and employee. After all to defame the union is defensive propaganda, and that never attains its object.

The propaganda that succeeds is not negative. It blackens no one. It simply relates what good is being done, and it tells these things not when the industry is being attacked but rather when the public is receptive to good impressions. Propaganda is most successful just when it seems least needed. When the public is in kindly mood, work on its feelings; when the public is sullen stay away, for even the best of explanations will be useless. Approached when angry Old Man Publicus will round on the interrupter with a testy "You're all alike." He isn't prepared to weigh the matter.

Just now the best way to establish the industry in popular estimation is by ending the frequent explosions that kill so many men and so powerfully impress and harrow the public mind. The industry can do nothing more constructive than to prevent these terrible holocausts. The coal mining industry by showing itself willing to rock dust its mines and to urge legislation demanding such rock dusting and by spreading the good story of its philanthropy in this matter can do more for the industry than by pages of negative propaganda.

There should be no skeletons in the coal industry's closet and if there are they should not be paraded. To publish pages about such skeletons is not constructive propaganda, however it may delight those who write it or please those who are thereby "defended." The merit of a statement lies not in its pleasing but in the effect it creates.

Time for New Laws

MINING laws passed with the best of intentions to assure safety are liable at some time later to have the opposite effect. Thus the mining law of Pennsylvania in its General Rule No. 25 declares that "All holes before being fired shall be solidly tamped the full length of the hole," the clause having reference only to gaseous mines. It has been found, however, that with air spaces less powder will do the work, do it better and will be less likely to break down, or blow down, at the back of the hole. Less powder and more

efficient operation means less danger. But there is the law requiring tight tamping and which prevents even the use of rock dust unless the dust is tamped so tight as to lose its cushioning effect. The industry needs new regulations and so far it cannot get any relief except by legislation.

In Great Britain the regulations are made and modified by authority duly constituted for that purpose by Parliament, and in Massachusetts, New York, New Jersey, Pennsylvania, Ohio, Wisconsin, California, Oregon and Washington and perhaps other states safety rules for other industries than coal are prescribed by administrative boards. It would seem better to leave matters of this kind to properly instructed and well-informed departments than to legislators who know nothing about the industry and who are afraid to make up their minds regarding something they do not understand. So much contradictory testimony assails them, the worth of which they cannot assess. Accordingly they do nothing which is perhaps better than inconsiderate action.

Probably some hardy person, coal operator or mine worker, will endeavor to oppose the use of electric safety lamps, rock dusting, electric shot-firing and other improvements when a new code is proposed and the legislators not knowing mining are likely to be moved by the opposition, but a commission would not make up its mind on the counting of noses but on a clear knowledge of the facts. Abuse might follow it, but it would certainly achieve more than the legislature which has allowed regulation to drift so that some legal provisions are now absolutely opposed to safety.

Are More Houses Needed?

OPERATORS are finding that it takes more houses to shelter their men than in former years. Rents in most cases have not gone up, but wages have. Consequently the mine worker finds the rent far from onerous. Some do not have to work as much as a whole day to earn enough to pay the rent for a month. Contrast that with conditions in the cities where 25 per cent or more of the month's wages is given to the landlord. For this reason there has been no disposition for employees to crowd as they do in the cities to save rent. The tendency is rather in the other direction.

In early days also there were more unmarried men or men who had wives across the seas. Now owing to the immigration laws we are not getting so many foreigners and another employee is more likely to mean another tenant. The demand for a house for every adult man is here, and here to stay. The accommodation once obtained will not be readily foregone, and the restrictive bars to immigration that would let in men with more modest requirements are not likely to be much lowered.

The only possible release for house shortage other than by new construction will come from the use of

more machinery, especially for loading and as a result of a concentration of the mine workings. The situation is indeed difficult especially in mountainous regions. There, what little space could be found at one time now is filled with garages. In fact a garage usually needs to be on the most desirably level ground where the owner of the machine can maneuver safely. This erection of garages has monopolized in many villages all the building space and in many cases garages have been built till sites have played out.

In some of the mountainous regions coke ovens have been pulled down to make way for houses, the ovens not having been used for years. This leaves the space formerly occupied by ovens, wharves and coke roads available for house erection. When there are not such spaces or where the coal company is not definitely certain that it will not have to use the ovens later, then there is no way of erecting dwellings except by excavating sites for both houses and roads; the steam-shovel and retaining-wall work often costing more than the erection of the houses.

Making of Anthracite

IN THIS issue is given a brief statement of John Roberts' views on the origin of anthracite. Very interesting and convincing does his story appear. Whether it is a true picture of what happened it is difficult to determine. It is puzzling to understand at first how large areas could have become heated between 500 to 550 deg. C. until one comes to Leonard Silver's theory that coal when heated between 400 and 500 deg. C. gives out heat from its own decomposition and so autogenous carbonization takes place.

Coal, of course, has not anything like the heat-giving qualities ascribed to it in commercial language. When asked the number of British thermal units in a pound of coal we glibly say 10,000 or 14,000 but that figure is the number of units of complete combustion. The thermal units that the coal itself by its internal chemical action can emit is greatly less. Many people do not know that coal has any such exothermic quality. Mr. Silver believes the coal might emit enough heat to extend its own carbonization so that given a nucleus heated to 400 or 500 deg. the carbonization might be extended without the presence of air somewhat as a fire is extended when air is present.

Unfortunately for Mr. Roberts' theory we are met with variations in the quantity of volatile matter in anthracite. The Bernice semi-anthracite and that of Forest City and the anthracite of Dauphin County, Pennsylvania have more volatile matter than that of the Middle and Southern Anthracite fields. The semi-anthracite of Arkansas and the Pulaski County field of Virginia are also instances of incompletely carbonized. Is it possible that these semi-anthracites reached only 400 deg. or a little more and that the exothermic action of the coal could be extended but without any marked rise of temperature above that given?

It is, of course, possible to believe that a slightly different quality of vegetal matter is the cause of the difference in volatile content. However, there are so many evidences of gradation in the volatile matter of anthracite and semi-anthracite that even Mr. Roberts' well-conceived thesis will not serve to convince those who hold, as most of us do, the metamorphic theory.

Many bituminous seams have been in places subjected to temperatures which coked or anthracitized

them. In those places the coal must have been in the exothermic stage. Why did not the action extend all over the seam as Silver has assumed it did in the case of beds now completely anthracitized?

These are the problems Mr. Roberts has to meet, but they are not any more or any less difficult than those the advocates of the metamorphic theory have failed to explain. We are still a long way from answering that riddle of the carbonizing ages.

Handcuffed to Precedent

TWENTY or thirty years ago the woods stretched down to the mine villages. Mills and mines alternated in the valleys. The scream of the saw mingled with the low boom of the tippie. The miners and the lumberjacks met in the barrooms and battled for supremacy. In the stream sawdust mingled with the ochreous waters from the coal mine. The shacks of the lumberjacks were occupied by miners and when the miners left, lumberjacks took their places whenever the men were themselves not lumberjacks and miners both, for the industries recruited from one another. When the ponds froze so that the mills shut down the millmen went underground and when the market for coal sickened the miners piled lumber in the mill.

In those days wood was cheap in some sections—\$4.50 per thousand f.o.b. mill—and paint relatively dear, so at first none and later few painted miners' houses, and the only color that adorned them was that of the dogwoods, buttonwoods, maples, hemlocks, firs and oaks that covered the hills. These made attractive bungalows out of the meanest of shacks. In many places, of course, houses had been placed even so long as forty or fifty years ago in serried rows. They needed decoration, but America had then hardly awakened to the value of beauty in utilitarian structures. Some will say it has not realized that value yet in any large measure.

The economic argument was the only one that appealed and that was more than dubious, for lumber was so cheap and the mines were so transient, being abandoned as soon as they were driven to the dip or the hauls became lengthy. Consequently painting was by no means common and was done in a perfunctory way when attempted.

For a while the industry was handcuffed to a precedent which it followed even after rope haulages, electric locomotives and big pumps extended mine life.

Times have changed. Today lumber at the mines nearly everywhere has to be shipped in, and even where it can be obtained from a mill by truck or wagon it is extremely expensive. It pays to preserve it with paint. That has been conceded. It pays to keep it painted. That is the next concession. Many have made it, but a few still hope for the best and leave the repainting for the future. The methods of painting in most cases need amending, as witness the water-paint on some houses, and the uncovered knot holes and flaky coatings on others.

No longer set among trees, no longer screened by nature the modern mining home is a ghastly thing unless kept painted. Lack of paint is half of squalor. Paint is half of cheerfulness, cleanliness and content. A freshly painted house delivers its message of thrift and hope everywhere and stamps a town with an attractiveness that keeps the roster of the company filled with the names of the best workers in the region.

Village of Rachel, W. Va.

Coal Industry Has Awakened to the Value of Paint

Inferior Paint Increases Painting Cost 75 per Cent—Why Ready Prepared Paints Are Preferred—Paint Guns Save Labor—Anyone Can Sling Paint Widely but Not Well—The Underground, a Land That Paint Forgot

BY ALPHONSE F. BROSKY
Assistant Editor, *Coal Age*, Pittsburgh, Pa.

FOR many years coal mines, being at the source of timber supply, painted nothing—not even the houses or tipples. Now the coal operator is beginning to paint everything, even his cars and the steel underground. The mine needed paint more than the surface but the practice of not painting was so well established that even today what would be painted for outside use is left unpainted for the severer service underground. Even the painting of surface buildings is neither sufficiently understood nor assiduously maintained.

How apparently simple, yet in reality how extremely difficult to most coal companies is the proper protection of building surfaces. When conversing with the man in charge of maintenance of mine property, the subject of paints and painting usually proves a tender spot. It is one of his principal burdens. This is wholly unnecessary, for neither the making of good paints nor their successful application are lost arts.

The requisites for successful maintenance of equipment by painting are few in number and are within the command of every coal company. In the order of their importance, these are: (1) The selection of a paint of proper quality and of a composition suited to the nature of the surfaces to be protected and to the conditions of exposure; (2) careful conditioning and

preparation of the surfaces to be painted; (3) application of the paint by experienced men who know how to use it; (4) adequate and intelligent supervision; and (5) regularity in applying paint to all surfaces subject to deterioration from the action of the elements. All these factors are well known, yet they are not always given due consideration. This may be judged from the difficulties and failures in the painting of equipment, dwellings and other buildings owned by the coal companies.

In all mining towns and plants, for protecting either internal or external surfaces, the best quality of paint should be used in preference to that which is less expensive but of inferior quality. This is because the better paint is more economical in the end. Actual figures show that the materials cost for two coats of good paint applied by brush to a smooth surface is no more than 25 per cent of the total painting expense. The remaining 75 per cent represents the labor of preparing the surfaces and applying the paint.

In making this estimate, it is assumed that one gallon of paint will cover 600 sq.ft. of surface and that one man with a brush should paint 1,200 sq.ft. of surface in eight hours; that the average price of good priming and finishing paint is \$2.50 per gallon; that experienced painters are paid at the rate of \$1.25 per hour and that a painter's helper paid at the rate of 75c. per hour can prepare 2,500 sq.ft. of surface in eight hours.

The folly of buying paint solely on a price basis is

NOTE—The Bertha Consumers Co.'s village, shown in the head-piece, affords abundant proof that it pays to paint mining villages well and as often as necessary. Most of the houses in this picture are of the bungalow type and contain four rooms.

Fig. 1—Painting Cost Shown Diagrammatically

An inferior paint costs as much to apply as one that is good. Apparent savings made in material purchased are thus deceptive, being far more than offset by labor expense.

readily apparent from a comparison of the cost of the protection afforded by high- and low-quality paints. Such a comparison is shown graphically in Fig. 1. High quality paint at \$2.50 per gallon should have a life of at least six years, while that of low quality at, say \$1.25 per gallon, must be applied every three years in order to afford adequate protection. Use of the more expensive but better paint in preference to the cheaper article effects a saving in labor that represents 75 per cent of the total cost. This comparison, although strictly theoretical, is fair and reasonably accurate.

Because good paints are scientifically manufactured, by processes in which advantage is taken of the physical and chemical properties of the various ingredients, and because during certain steps in the process temperatures of manufacture are highly important, no one under ordinary circumstances should attempt to mix paint on the job. So thoroughly has the manufacture of good paint been reduced to a science, that even its coefficient of expansion is taken cognizance of and predetermined. Almost everyone has noticed at some time or other that the coat of paint applied to corrugated metal has cracked. This often results from the unequal expansions of the paint and the metal upon which it is placed.

The necessity for refinements of this nature in the manufacture of paints, particularly those intended for covering metal surfaces, is obvious when one considers the average range in temperature between midnight and noon. This sometimes amounts to as much as 60 deg. F. Paints covering surfaces that vibrate under the stresses set up by machinery, as for instance the coverings of tipples, must also be elastic and non-shattering; otherwise, they will crack and scale. As a matter of fact, however, all paints for ordinary purposes should form tough elastic coats. These, however, are only a few of the requisites that must be taken into consideration in making a paint and are here mentioned

merely to show that it is economical in the long run to use a paint of good quality that has been scientifically compounded and manufactured.

In mining towns house paints of light tint are desirable because they present a good appearance. Many prominent coal-mining companies throughout the United States invariably use paints of light color. Nevertheless, under certain specific conditions, as where houses closely adjoin tipples and consequently lie in the path of wind-blown coal dust, or are built in the proximity of coke ovens where they are subjected to the action of sulphurous gases, darker shades may be advisable.

Even the very best of paint must be used with discrimination. Thus a paint of specific composition cannot be utilized for all surfaces under a wide range of conditions. The paint used for covering the side walls of a house may be utilized on a fence also, but it should not be used on porch floors or steps. For these latter surfaces a paint must be able to resist abrasion and exposure to the weather. This is accomplished by compounding with it a durable varnish and other necessary materials. Good paint sometimes fails because it is applied to the wrong surface.

Coal companies that use inferior paints almost invariably choose the same interval between paint applications as do those firms who employ a paint of the highest quality. As a general rule, where an honest effort is made to preserve them, the buildings in mining towns are painted every four or five years. This is a period within the durability of good paint, when employed under favorable conditions.

Time is the only infallible test of the quality of a paint and its proper application. Any company that finds it necessary—although it may not choose to do so—to paint its buildings at intervals of only two or three years, is losing money in upkeep and in the application of the paint.

Good paint fails slowly by oxidation and powdering from the outer surface inward, a surface covered by

Fig. 2—Paint-Time in Lynch, Ky.

After spending millions of dollars in developing its mines and building the town and plant, the U. S. Coal & Coke Co., intends to preserve its buildings by painting them as often as may be necessary.

it requiring little preparation for repainting. After repainting, such a surface receives additional protection by reason of the old or under coats of paint not completely worn off. Poor paint fails by blistering, peeling, "alligatoring," scaling and the like, so that before a good paint can be properly and effectively applied to a surface that has already been covered by a poor paint, the underlying coat must be scraped and brushed to remove blisters, peeled spots, and the like, which are the manifestations

of poor quality or inferior application. The cost of preparing a surface in this way exceeds any saving that may be made by the use of a poor instead of a good paint.

It is false economy to forego the expense of painting until such time as exposed wood surfaces to be coated are dry and cracked for want of paint, or the metal surfaces show signs of corrosion. Thus neglected, surfaces present a shabby appearance, deteriorate rapidly and can be repainted only at an increased cost, because additional cleaning is required. Wood that is dried out and metal that is pitted or corroded absorb far more paint than similar materials properly conditioned. More labor also is expended in spreading the paint.

At this point, a few words on the preparation of the surfaces to be treated and the tempering of the paint may not prove amiss. Best results are obtained only when every detail is carefully observed. The surfaces of outside structures should not be painted immediately after a rain, in a damp atmosphere or during cold weather. All surfaces to which paint is applied should be thoroughly dry. A warm, dry atmo-

Fig. 3—Surface Preparation

The surface, if covered with loose particles of old paint, dust or mud, must be cleaned with a wire brush before being painted or the paint will not adhere.

sphere, such as that obtaining between spring and fall is ideal. Under other conditions, the paint cannot be made to adhere to and penetrate beneath the surfaces treated. The paint must always be thoroughly brushed on if a good wearing surface is to be obtained.

Wood in newly erected structures should be given a thin first or priming coat and then allowed to season for a period of three or four months before the second coat is applied. This seasoning eliminates the free water in the wood cells which, when thus emptied, absorb appreciable quantities of the paint.

MUD AND DIRT MUST BE CAREFULLY REMOVED

The ground on which mine houses are built is frequently neither level nor sodded. Furthermore, few miners' dwellings are provided with roof gutters and down spouts, so that the dripping of water from the eaves spatters more or less mud upon the outside walls of the dwellings. Houses built in the proximity of coal tipples also may be covered with a thin layer of coal dust.

All foreign matter of this kind should be removed by the use of wire brushes before paint is applied. Loose scaly paint should also be removed, if necessary by scraping, brushing or sandpapering. Sap streaks in new wood should be treated with turpentine, and glossy spots on paint-covered surfaces should be roughened prior to painting anew. It is also needless to mention that repairs to the woodwork of houses or other structures should precede painting.

Priming paint should be thinned before being applied and all paint should be kept thoroughly mixed by frequent stirrings. When two coats are to be given a surface that has previously been painted, the priming coat should be thinned by the addition of undiluted raw linseed oil and turpentine. The exact quantity of thinner used will depend upon the character of the surface treated, the kind of paint and other factors. The correct tempering of paint ordinarily cannot be accomplished by inexperienced men. Intelligence and skill derived from experience are necessary qualities of any person in direct charge of painting.

Painting of buildings is admittedly attended with difficulties, but steps usually can and should be taken to overcome them. Under no circumstances should the painting of an individual dwelling be left to the occupant, neither should the responsibility for painting mine structures be delegated to surface-plant crews. Some companies solve their residence-painting problem

Fig. 4—Paint Gunning

Money can be saved by spraying the first or priming coat. With a machine a man can cover from two to four times as much surface as he can with a brush. Two sprays can be operated from a single compressor unit.

Fig. 5—Brushing on the Second Coat

Two large coal companies are agreed that the finishing coat should be applied with the brush. Light-colored paints are preferable to more somber hues for miners' dwellings.

by supplying paint to their house tenants. This is usually applied on idle days and in a haphazard manner. The only advice that can be given in a case of this kind is, "Don't do it."

As a general rule, each coal company should do its own painting. The degree of success attained in this work will depend in large measure upon the skill of the men employed, consequently as many as possible of the painting gang should be experienced workmen. It is fully realized that it is not always possible to secure the services of any large number of experienced painters, and for this reason it frequently becomes necessary to hire men that are untrained to assist in the work. This is particularly true when the painting program is large and has to be completed in one season so that a comparatively large number of men must be employed. However, there is one way out of this difficulty, and that is the employment of one or more permanent paint crews.

By this arrangement, unskilled men work in a measure as apprentices under the supervision of those experienced in painting. They are thus soon trained to do their work well, and, having received this training, they should be retained as permanent assets to the mining organization. Of course, extensive painting programs can only be performed during the summer months, and it is therefore suggested that throughout the rest of the year these men be employed as general handy men and placed in the maintenance department under the supervision of a master of maintenance.

In weather not suited to painting, they may be employed in repairing roofs, windows, porches, fences and the like. The size and number of paint crews employed may be fixed by scheduling the various jobs of painting in one or in several plants. The skill attained by these men when employed at odd jobs is ample justification for organization in the manner described.

Those companies that cannot profitably retain a permanent maintenance department or doubt its efficacy, may well let their painting jobs on contract. This, however, should be done only to reliable contractors. It is better to let out a company's painting to some outside person than to employ green men on this class of work, for good painting requires skill. Contract painting is not, however, entirely satisfactory, because an unprincipled contractor has small interest at stake; his remuneration is based on the area covered, and the

quality of his workmanship will display itself only after months or years of exposure to the weather.

The unscrupulous contractor may accordingly instruct his men to thin the paint excessively in order to save material and labor in its application. He may employ a small or large number of inexperienced men or he may use an inferior quality of paint. For these reasons, coal companies should specify the make and kind of paint that shall be used on their buildings. They may further employ one or two inspectors constantly to supervise the work.

Coal companies, operating in isolated districts where it is difficult to get painting done on a contract basis, may well "import" several experienced painters to direct the painting of their buildings. The importance of having this work done "according to Hoyle" cannot be over-emphasized.

At the present time, a number of coal companies are applying paint with spray machines. With these devices, the paint is projected in a spray by compressed air from portable nozzles or guns. The equipment consists of two units—one compressing and distributing the air and the other containing and distributing the paint. The principle of operation of this device is somewhat similar to that of a cement gun. A pressure of about 10 lb. per sq.in. is maintained in the paint container to force a steady stream of this liquid through a flexible hose to the nozzle, where it is met and atomized by a current of air conducted from the compressor unit at a pressure of about 50 lb. per square inch. A spray machine usually supplies two guns which may be moved about within a radius equal to the length of the flexible hose employed.

Last summer the Hillman Coal & Coke Co., used spray machines in painting several of its towns. It reports that the cost of applying paint by the spraying process is less than by brushing, although the spray method consumes 10 to 15 per cent more paint. The difference in consumption between the two methods is greatest on windy days when a portion of the paint used in spraying is blown away. Although authorities differ as to the durability of paint applied by these two methods, some claiming that one is as good as the other, and others asserting that sprayed paint does not last as long as that applied by brush, this company is not discouraged with the results attained. Heretofore, it has applied both coats with the spray gun, but in future it intends to apply the finishing coat with a brush.

In painting its houses at Lynch, Ky., the U. S. Coal

Fig. 6—A Well-Maintained Substation

Proper painting of wood and metal surfaces in and about mining plants must be given adequate consideration by mining companies inasmuch as total upkeep costs are materially reduced thereby.

& Coke Co., uses spray machines in applying the first coat and brushes on the finishing coat. This town contains 991 houses, which should be painted at five-year intervals. All these houses were painted during October and November of 1922, and June and July of 1923. The entire town was thus painted during these four months by a crew of forty men and two foremen, work being carried on for 10 hr. per day. One spray machine was used on this job.

The air compressor used with this spray gun was driven by a gasoline engine and carried on a truck. This latter was moved from place to place by an automobile truck which also transported ladders, paint and the like. Three men are employed to operate the spray machine; two nozzle men and an attendant who looks after both the paint supply and the compressor itself. This crew can paint an area of 20,000 to 30,000 sq.ft. in 10 hr. The automobile truck mentioned is utilized not only for moving the spray machine, but also for supplying the brush painters with equipment and materials. Nine crews of four men each prepare the surfaces for the spray machine and brush on the finishing coat and trimmings.

Painting tipples either of wood or steel and maintaining an adequate protective paint covering upon them

Of course, all tipples, regardless of their material of construction should be carefully and thoroughly cleaned before they are painted or repainted. A manufacturer of paint reports that tipples, "if of steel construction, should be painted immediately upon erection to avert corrosion. Before being painted, however, the surfaces should be washed down with a solution of acetic acid and water in equal parts, or vinegar and water. This solution will cut the grease and insure the adhesion of the paint to the metal. Either a well-prepared paint or one of many paints made especially for metal surfaces may be used." For tipples, however, a sulphur-resisting paint should always be specified, because all coal dust contains more or less sulphur.

In the interiors of mine power plants, if paint is regularly applied to the walls, floors, railings and other objects in the generator rooms it adds greatly to their appearance, affords better illumination and acts as an incentive to employees to keep the plant clean. The bad effect of steam and gases upon metal can be counteracted by the periodic painting of surfaces susceptible to such action in the boiler and pump room. Paint also protects metal from acidulous gases escaping into the plant from the boiler furnaces. The importance of carefully painted interiors in substations should also

Fig. 7—Upkeep Indications

House painting is only part of the village upkeep; roads should be scraped, ditches cleaned and fences whitewashed. Good upkeep pays both in cash and in morale. A neat town attracts the type of men who work steadily, cooperate with the management and so make **operation** pleasant and profitable.

are not simple tasks by any means. It must be remembered that surfaces and structural members on tipples are neither smooth nor accessible and that they are covered with coal dust and smeared with oil and grease. Painting such surfaces by hand is tedious and slow. Spray machines cut this labor cost 50 per cent or more. It is estimated that it would require eleven men twenty-six days to brush one coat of paint on the big Lynch tippel, which has an area of 101,365 sq.ft. With a spray machine, this area could be covered by the same number of men in about one-half the time necessary for brush painting. It is further estimated that good paint properly applied to this tippel should last for five years. The Gary division of the same company is of the opinion that steel and concrete tipples should be given one coat of paint each year to eliminate the uncertainty of protection afforded by paint applied at greater intervals.

Many wooden tipples throughout the country are going to rack and ruin simply for the want of paint. Owners of these structures may well take a lesson from the Bertha Consumers Co., of Pittsburgh, Pa., which takes as good care of its tipples as it does of its houses, applying paint promptly whenever needed. Wooden tipples should be painted in the same manner and with the same material as are mine villages.

be recognized by all coal-mining companies, as it is already by transit companies and in most cases by public utilities.

Structural and other steel with the exception of rails that are stored in supply racks or yards should be painted to protect them from corrosion. Such steel is normally painted as soon as erected but much corrosion may be avoided by painting it as soon as it is unloaded from the railroad car.

Both intricate and simple piping systems should be given paint protection, otherwise they may deteriorate rapidly. Pipes, other than those conducting steam and consequently covered with asbestos, ordinarily should be given a coat of durable paint of a color conforming to established company convention. A "color scheme" for pipe facilitates repairs.

Underground structures and equipment should by no means be overlooked in any campaign for paint protection, although its possibilities are more limited there than on the surface. Underground substations and pump rooms should be as carefully painted as similar stations above ground. Iron doors, gear guards, lockers and tool boxes all last longer when painted.

Another big opportunity for saving is afforded by the painting of equipment installed in underground

machine shops. Dumps and other apparatus installed at shaft and slope bottoms may also be preserved by paint, as also may steel-timber sets provided they are painted immediately upon erection. These may advantageously be painted white to increase their visibility. When a piece of mining machinery of any kind is taken to surface shops for complete overhauling, it should be painted before being returned to service. It is asserted by some operators that even the outside surfaces of mine cars should be painted, this practice being followed at certain mines. Some operators claim that painting will double the life of car bodies.

At What Heat Was Anthracite Formed?

FINDING that in South Wales, anthracite is freer of ash than bituminous coal, Dr. Strahan has surmised that it was derived from a different type of vegetation and was a metamorphosed development of bituminous coal. Jordan and Burns attempted to account for the purity of Welsh anthracite by ascribing it to the removal as chlorides of the various ash constituents, stating that chlorine may have combined with the metallic oxides in the coal to form salts and thus leached out ashy constituents.

In South Wales anthracite has sometimes, even frequently, only 1 per cent of ash. In the United States we are not faced with the problem of explaining any such low ash content. The shoe is rather on the other foot. However, in South Wales, the low ash percentage has made several geologists disposed to reject the whole metamorphic theory.

In the Darwinian theory, as popularly interpreted, all living things are in a common chain of development, the superior beings derived their existence through a line of inferior beings still existent. The progenitor of man is the ape. The Darwinians are more circumspect. Man is derived probably from some other primate, the family not being definitely known. Just so with anthracite according to some geologists; it comes from vegetable matter, so does bituminous coal, but one is not necessarily derived from the other.

Now comes John Roberts strongly supporting the metamorphic theory in a scholarly paper read before the South Wales Institute of Engineers. He declares "Anthracite is a natural product of low-temperature carbonization, the parent substance having consisted of bright coal, probably both clarain and vitrain and which has subsequently attained in the earth's crust a temperature of between 500 and 550 deg. C." Note the temperature; it is a high one and he has a hard time proving his case against authorities who have said quite dogmatically that the temperature could not have exceeded 300 deg. C. and against still others who think that if we only wait some millions of years the lignite of the Dakotas will be turned into anthracite.

He makes only a poor fist at explaining the clean anthracite of South Wales. The best he can do is to quote Dr. Lessing who places the average ash percentages of fusain at 15.59 per cent; durain at 6.26 per cent; clarain at 1.22 per cent and vitrain at 1.11 per cent. As anthracite, unless it is leached, should have naturally more ash than bituminous coal because it has lost volatile matter, the clarain and vitrain percentages of ashes given would figure nearly 2 per cent instead of 0.8 per cent which South Wales anthracite

In fact, the opportunities for saving which paint affords in the mining of coal appear to be almost limitless. Few companies seem to have made any great effort to ascertain how much can be saved in that manner; none at least have proved its limits. When these opportunities are appreciated, fewer renewals of mining equipment and appurtenances will be required. It would appear that it is high time that the coal industry woke up to the fact that large savings can be made by the use of paint. The field is as yet barely half explored but promises abundant reward to those who fathom its possibilities.

is known to contain. Mr. Roberts recognizes this and quotes Leonard Silver as having found a gas coal having only 0.5 per cent of ash with an ash content in the vitrain of only 0.486 per cent. He instances also a coal that he himself obtained from Warsaw, with a moisture content of 7.8 per cent and volatile matter of 36.7 per cent, which had 1.2 per cent of ash but only 0.43 per cent in a bright band picked from the sample.

But to get back to the carbonization theory. Mr. Roberts has little difficulty in showing that both sub-graphitic luster and iridescence can be obtained when bright coal is heated under favorable circumstances to a temperature of 500 deg. C., that the coal fuses and loses its true cuboidal form.

He shows that when bituminous coal is heated to 500 deg. C., it loses volatile matter whereas anthracite coal does not. It seems somewhat feasible to claim with Mr. Roberts that the reason why anthracite does not evolve volatile matter at 500 deg. C. is because "it has been there before" and has already lost all the volatile matter that could be evolved at that temperature. The same conditions exist with semi-coke. It does not respond to a temperature of 500 deg. C. because it has already given out all the gas that temperature can call forth.

Similarly with the evolution of ethane, propane, etc. This is given off in quantity by bituminous coal below 600 deg. C. but neither semi-coke nor anthracite can be induced to part with any at any such temperature. It is also stated that when coal is heated between 400 and 500 deg. C. it passes through an exothermic stage, that is, without the presence of air to burn away the coal, the heat of decomposition was such as to continue the heating process. In fact Leonard Silver has suggested that if, by plication of the coal measures, one portion of a bed was raised to that temperature the action might extend throughout the field provided the surrounding strata were of such low conductivity as to prevent the heat from escaping and that the pressure of the overburden was enough to keep the evolved matter liquid and not gaseous. If gases were formed Leonard Silver surmised they would perform enough external work to lower the temperature below the exothermic point.

Mr. Roberts also calls attention to the fact that much of the substance in bituminous coal is soluble in pyridine. None of the substance in semi-coke is soluble in pyridine and none in anthracite. He is disposed therefore to believe that the coal has been raised to the temperature at which semi-coke can be made. He concludes for these reasons that the temperature of carbonization to which the coal was subjected was between 500 and 550 deg. C.

Surface Works of Old Ben No. 9 Mine

How Old Ben Corporation with Rock Dust Extinguished Seven Mine Explosions

Zone System vs. Coating System—Relative Advantages of Floor, Rib and Roof Dust—Frequencies of Application—Effectiveness of Dust Distributed by Air Current—Sampling by Vacuum Cleaner

BY J. E. JONES

Safety Engineer, Old Ben Coal Corporation,
Chicago, Ill.

NEARLY seven years have now elapsed since the Old Ben Coal Corporation, which considers safety as being as fundamental and important a requisite as production, commenced applying rock dust to its mines. In that time the dust used has suppressed seven explosions. From the experience gained a rough appraisal can be made of the relative effectiveness of the various types of rock-dust protection, of the means by which that protection may be afforded most readily and of the frequency with which dust applications must be made.

There are two general methods of rock dusting. The first may be called the zoning system, and the second, the coating system. The first implies placing rock dust in abundance at regular intervals throughout the mine, so located that it may be easily thrown into suspension in the event of an explosion. By this means the explosion flame is extinguished at the first rock-

dust zone or barrier with which it comes in contact. The second system entails maintaining the ash content of all mine dust at a percentage so great as to prevent

ignition, thus making a practically continuous rock-dust zone out of the entire mine. Each method possesses its own advantages and disadvantages, but fortunately the weak points of the one are the strong points of the other, so that a combination of the two systems affords ideal rock-dusting protection.

The Old Ben Corporation at first adopted the zoning system, chiefly because the panel system of mining afforded an excellent opportunity for zoning the underground operations, each panel forming a separate zone. In that system of

mining, main entries are driven in opposite directions from the shaft bottom; at intervals of 1,500 ft. cross entries are driven in opposite directions at right angles to the main entries. Again at intervals of 500 ft. along these cross entries, panel entries are turned in opposite directions at right angles to the cross entries. Each panel contains a maximum of 34 workers, including company men.

BARRAGES VERSUS COATING SYSTEM

AS a result of seven years experience in rock dusting, Mr. Jones is of the opinion that: The panel system of mining favors the zone system of rock dusting. The zone system of dust distribution is particularly suitable to abandoned workings which can have no other dust protection; it also affords dust for extinguishing mine fires. The coating system is less expensive than the zone system and is especially valuable when applied to roof and ribs. First two applications of dust should be less than three months apart. Three or four applications should be made during the first year and two per year thereafter. Dust should be blown into air courses at every third crosscut.

NOTE—Article read at Cincinnati convention and exposition, American Mining Congress, May 16, 1924. Article illustrated chiefly by photographs provided by W. D. Holman, mining engineer, Phelps-Dodge Corporation. They represent practice at the mines of that company.

Fig. 1—"Excuse My Dust"

At the Phelps Dodge mine in New Mexico where this picture was taken the haulageway is treated with adobe dust several inches deep. Dragging the evergreen tree behind a trip stirs this dust up to float in the air current and be deposited on roof and ribs where it will be most effective

In this firm's early rock-dusting experience, a shale-dust barrier was installed at each entry intersection; later, intermediate barriers were installed in some of the mines midway between the regular barriers. The distance between panels being 500 ft., the centers of the regular dust zones or barriers had to be placed that distance apart. Each zone extends 100 ft. in each of the four directions, leaving a distance of 300 ft. between the larger barriers. When intermediate zones were installed they cut this distance in half, leaving a distance of approximately 150 ft. between zones.

Each zone consists of an Old Ben concentrated barrier installed over the haulage road, outby from each panel. The roof and ribs of the haulage road also are coated with rock dust for 100 ft. in all four directions, and dust troughs are likewise installed for 100 ft. in all four directions in the aircourses, these latter passageways not being provided with tracks. Troughs and platforms piled with rock dust also are installed at the side of the track in each zone territory wherever space permits.

The type of concentrated barrier employed is an overhead construction with a capacity of from $1\frac{1}{2}$ to 3 tons of rock dust. It is so built that should it be tripped accidentally or mischievously, no injury can result to any person who might be directly under it or approaching it on a rapidly moving trip. The wooden troughs containing the dust are supported and balanced in shallow notches, so that a slight force easily overturns them. Each trough holds approximately 60 lb. of rock dust.

The advantages of the zone system of rock-dust protection are: (1) The rock-dust barriers are favorably located, for they are placed at the intersections of passages which serve territories that are expected to remain in working condition over an indefinite period

of time. (2) They also, when placed at the entrances to old workings that are themselves inaccessible, afford effective protection to those abandoned areas. This is important as such abandoned places generally entail a greater hazard than is encountered elsewhere. (3) The abundance of rock dust installed under this system at regular intervals provides a barrier through which it would be difficult to force the flame of an explosion even though the gas content and the mine dust present were of a character that otherwise would permit of its propagation. (4) The system provides an abundance of rock dust in aircourses and other passages in which track is not laid. (5) Such a large quantity of rock dust is provided in each trough that even when moisture commences to harden it only a thin crust on the exterior is subjected to the hardening. (6) The system provides rock dust in quantity and condition suitable for the combating of mine fires.

The disadvantages inherent to rock-dust zoning are: (1) The cost of installing dust barriers is high compared to that incurred in the coating system. (2) Ignition of coal dust and propagation of explosions are not prevented within panels or between rock-dust barriers. (3) This method of mine protection is not equally well adapted to all systems of mining.

To a limited extent, the coating system of rock-dust protection was employed by the Old Ben Corporation at the beginning of its use of inert dust. This coating was applied on the haulage entries in the rock-dust zone in an effort to secure as efficient a supply of dust as was used in the aircourses. This dust was spread by hand.

Development of a successful rock-dusting machine was retarded by the many reports circulated concerning the difficulty of applying rock dust to a surface by

mechanical methods. Three devices have been tried, namely, a hand-power machine, one operated by compressed air on the principle of an aspirator and an electrically-driven, high-speed fan. The latter device has proved successful.

The machine now employed is of such capacity that 2,000 to 3,000 lin.ft. of haulage entry may be dusted per hour by two men, making a distribution of 2 lb. of rock dust per lineal foot. The fan is driven by a dust-proof motor, and the dust is automatically fed into the discharge line and directed onto the side of the entry. It thus requires two passages of the machine to complete the dusting of one entry. To double the speed of dusting would require only a machine of twice the capacity with a discharge pipe upon either side.

The success of the dust-coating system for passageways equipped with track has been established. Its usefulness depends on the low relative first cost of the equipment and the high ash content of the mine dust along the passageways where the rock dust has been applied.

A strong combined air-and-dust blast performs other duties that are important. Among these might be mentioned: (1) The coal dust in the path of the blast is forced into suspension in the air and thoroughly mixed with the rock dust. (2) Coal dust is forced out of crevices and small holes in the coal rib and from the timbers and is replaced by rock dust forced under

high pressure into these small openings. (3) High places that are usually timbered always contain a large quantity of the finest of coal particles. Such places are easily accessible to the strong air-and-dust blast. (4) Where the coating method of applying stone dust is employed, the walls and roof are whitened, thus improving the illumination of the roadways.

The coating method of dust application requires that greater dependence be placed upon the analysis of the mine dust than is necessary with the zoning method. The Old Ben company has taken samples of dust before and after coating applications, obtaining in part the results set forth in Tables I, II and III. In Table I it will be noted that the ash content was higher than normal before dust was applied. This was because rock dust was carried by the ventilation current when the rock-dust zones were installed and deposited in the intermediate areas. Tables II and III show respectively the analyses of samples taken after the first coating application and an analysis of a sample of the shale dust itself.

These tabulations show that a finer mine dust is to be found after the application of the rock dust than before it has been applied. Sample 6 was taken four months after a coat of dust had been spread and its analysis shows that the ash content has decreased. Experience has demonstrated that the first two applications should be less than three months apart and that three or four applications should be given at regular

Table II—Samples Taken After First Coating Application

intervals during the first year, after which probably two applications per year will be sufficient. One of these should be applied in midsummer when the moisture on the various mine surfaces will assist in causing the rock dust to adhere to roof, ribs and timbers.

In aircourses where no track is laid, the application of rock dust does not give the high degree of satisfaction afforded by the direct application of rock dust to ribs and roof. This is obvious inasmuch as the aircourse cannot be reached directly by the discharge from the rock-dusting machine and suitable tubing must be employed for this purpose. Thus dust can be introduced into these headings only at intervals, the length of which depends upon the distance between crosscuts.

The length of aircourse that can be efficiently treated by this method depends almost entirely upon the velocity of the air current and the length of time during which the dust is blown into the passage. Experiments show that with an air velocity of 680 ft. per minute, 61 per cent of the dust blown into suspension is deposited on the floor and 17 per cent on the roof and ribs in the first 100 ft. of distance from the point of dust introduction.

Again, the records obtained from blowing 4,000 lb. of dust in 50 min., into an air current traveling at a velocity of 680 ft. per minute, which speed of travel was maintained uniformly throughout 2,600 ft. of an entry 7x14 ft. in cross-section show the following results throughout this distance: At 100 ft. from the point of introduction, 14 lb. of dust were deposited per lineal foot of entry; at 600 ft. deposition had decreased to 9.3 oz. per lineal foot; at 1,200 ft. it was 3.8 oz. per lineal foot, whereas at 2,600 ft. from the point of dust introduction, 1.7 oz. was deposited per lineal foot of entry. From 600 ft. to 2,600 ft. from the source and apparently beyond this point, the deposition of rock dust on the roof and ribs was equal per square foot of area to that upon the floor.

It was apparent that even at appreciable distances from the source of dust introduction, a large quantity of dust is in suspension in the air, but the actual weight of the material deposited is small and the quantity adhering to the sides of the passage is of little value after even a comparatively short length of heading has been traversed.

Rock dust on the floor of an airway is of some value, but is not as effective as an equal quantity deposited on the roof and ribs. This is because of the following reasons: (1) It covers and is mixed with a mine dust of higher ash content than that deposited on the roof and

Table III—Sample of Old Ben Shale Dust

Volatile Matter, Per Cent	Fixed Carbon, Per Cent	Ash, Per Cent	Moisture, Per Cent	Per Cent Through 20- Mesh	Per Cent Through 48- Mesh	Per Cent Through 100- Mesh	Per Cent Through 200- Mesh
5.9	0.6	90.7	2.8	98.5	98.1	97.3	88.4

ribs. (2) When in contact with a fireclay floor, rock dust is apt to absorb moisture, so that it becomes difficult, if not impossible, to throw it into a cloud in the event of an explosion. (3) Rock dust deposited on the roof and ribs is advantageously located as it may be easily forced into suspension in the mine air. (4) Dust on the floor is subjected to more rapid deterioration and is far more liable to be covered up by falls of rock from the roof than is dust on the ribs.

In order to give an aircourse a coating of rock dust, approaching in efficiency that applied to haulageways, requires application of dust at frequent intervals. Such intervals should not exceed in length the distance between three successive crosscuts, or about 180 ft. This necessitates that small well-fitting doors be installed in every third stopping. These, however, must be large enough to permit the passage of a man. Part of the equipment carried by the rock dusters operating the machine is a board slightly larger than the doorway in these stoppings, near the bottom of which is a circular hole of the same diameter as the canvas dust tube. This tube may be slipped through this hole and the board placed over the open doorway.

In order to eliminate all guesswork, dust is blown into the aircourse at each station for a definite period of 10 min. By this means, 800 lb. of dust is supplied to each 200 lin.ft. of aircourse, the present machine handling dust at this speed. This gives an average of 4 lb. of dust per lineal foot of passage treated. After the first two or three applications, the time of dusting at each station may be reduced to five minutes.

The chief advantages of the coating system of dust application are as follows: (1) The dust application is highly efficient, especially on haulage roads. (2) The cost of applying dust in this manner is low compared to that entailed by the zoning system. (3) It is possible to protect the entire mine within reach of the haulage system by increasing the ash content of the mine dust above the limit where explosion propagation is possible. (4) Coal dust, especially that which has been deposited on timbers, lagging, etc., and which is extremely fine and low in ash is dislodged and non-explosive rock dust is deposited in its place. (5) The efficiency of this method of dust application is not dependent on or affected by any system of mining that may be used.

The disadvantages of this method of dust application include the following: (1) It is impossible to treat abandoned workings. (2) Coal dust in aircourses is not thoroughly mixed with the rock dust, and it is possible that coal dust on the roof and upper portions of the ribs are not effectively coated with the rock dust. (3) The effectiveness of the protection afforded by an entry well dusted with the coating system de-

Fig. 3—A Compressed Air Dust Blower

A small compressor carried on another truck furnishes the air for the operation of this machine. A hose may be attached to the dust nozzle of this machine and the dust directed against ribs or roof anywhere within its reach.

creases more rapidly than does that of a well-installed dust zone. This arises from the passage of trips and the falling of particles from roof and ribs which displace the rock dust, as well as from the continuous deposition of coal dust. With the coating system, the ash content of the mine dust gradually decreases, so that with this method of protection, close supervision must be provided and frequent applications of dust must be made.

BEST TO COMBINE ZONING AND COATING SYSTEMS

Neither of the two systems just described can, of itself, assure complete protection against local coal-dust explosions. The greater territory protection and lower installation cost of the coating system, however, puts it in first place, and establishes it as the method to be preferred. Ideal protection can be obtained by using the zoning system as an auxiliary to the coating system. Thus a permanent barrier can be installed at the entrance to each main cross-entry section, at the entrance to each abandoned territory and at intervals of 500 ft. along aircourses. Installation of such dust barriers will be low in first cost, as troughs can be employed exclusively in all places mentioned except that a concentrated barrier should be installed at each main cross-entry entrance. In addition to affording the mine full protection against the propagation of coal-dust explosions, this method would also furnish an available rock-dust supply at regular intervals suitable for fighting fires.

As has been suggested previously the analysis of mine-dust samples in those operations employing the coating system of rock-dust distribution, is an important factor in the supervision of this work. Correct analyses depend largely upon correct sampling. The usual pan-and-brush method of dust collection is not satisfactory, because the most dangerous dust is carried away by the ventilating current.

The Old Ben company accordingly collects dust samples by air suction, using for this purpose an ordinary vacuum cleaner such as is employed in residences. From this machine, however, the handle, wheels and dust bag are removed and small bags employed to collect the samples. The motor, of course, must be suited to the electric current used in the mine. In operations not electrically equipped, a hand-operated suction device may be employed. In such mines also, some other power must be used to operate the rock-dusting machines.

The promotion of safety differs from other departments of industrial activity in that an exact knowledge of the degree of success achieved is always lacking.

Fig. 2—Dust Blower to be Mounted on a Truck

In this device a fan driven by a motor blows a cloud of rock dust into the air current which carries it and deposits it everywhere on the mine surfaces. This machine is particularly adapted to use on haulageways and tracked headings.

Fig. 4—Another View of Machine Shown in Fig. 3

The compressor supplying air and the hose for delivery of the dust are here plainly visible. This outfit will treat almost any surface within the mine that lies within a hose length of the track.

Other departments can, in a relatively short time, show in dollars and cents, or by some other measure, the degree of success or failure that a device or method has attained. Visualization of the progress made in safety methods and appliances depends largely upon statistics and these in turn are dependent upon such a multitude of contingencies that the information desired is often difficult to obtain. The measurement and tabulation of the results of an accident that has occurred is a simple matter, but the similar treatment of an accident that has been prevented by a safety device or method is certainly not simple and the damage such an accident would have caused had it not been prevented can in many cases not be measured in any way whatsoever.

This is in part true of the experience of the Old Ben company with rock dust. In most instances, it is impossible to determine whether an explosion would have proved disastrous had it not been for the rock-dust installation. It is always possible, however, to ascertain whether the rock dust arrested the propagation of an explosion. This much is certain, the flame of an explosion has never passed through a rock-dust barrier in the mines of this company.

OF MINE EXPLOSIONS SEVEN WERE STOPPED

Since the installation of rock dust was begun in the winter of 1917-18, nine explosions have occurred in these mines. For the purposes of the present study, these may be grouped as follows: (1) Those in which the explosion flame did not reach the nearest rock-dust barrier. (2) Those that originated within a rock-dust zone. (3) Those in which the explosion flame reached a rock-dust zone, but was not of such violence as to render it certain that the explosion would not have stopped had the dust zone not been installed. (4) Those in which the explosion flame reached a rock-dust zone and manifested such violence and heat that no question exists but that a disaster would have resulted, had it not been for the rock-dust installation.

In the first group, it is immediately obvious that the rock dust played no part in allaying the explosion. Two such explosions have occurred and in both instances the rock dust at the nearest zone was thrown into suspension.

Four explosions out of the nine can be classified under group 2; one of these was violent, knocking down I-beams, blowing out concrete stoppings and charring the flame side of the collapsed concentrated barrier as far as the flame traveled. It is probable

that this explosion would have been disastrous had it not been for the rock dust. In this instance the flame-affected territory measured 100 ft. in length. The other three explosions coming under this classification were not particularly violent, but two of them developed intense heat.

One of the nine explosions mentioned may logically be placed in group 3. The evidence visible after the explosion did not indicate much flame or violence, although the men in the vicinity were emphatic in their statements that the flame filled the entire entry until it reached the rock-dust zone, where it was extinguished instantly. The origin of this explosion was less than 100 ft. from the barrier.

In group 4, two explosions may be placed. There is no question but that disasters would have followed both of these ignitions had it not been for the rock-dust barriers. In each instance, the force of the explosion was evident for over 3,000 ft., but the flame was extinguished at the first rock-dust barrier encountered.

EXPENSE OF ROCK DUSTING NEED NOT BE GREAT

Pioneer work in rock dusting performed by the Old Ben corporation has been expensive, but it would not necessarily be so for other companies seeking rock-dust protection. The experimental stage in rock dusting has practically been passed and until some other and better means for preventing coal-dust explosions is developed, this method is established.

Application of dust by the coating method assisted by barriers at suitable intervals will render essential only one-fourth the number of troughs and one-tenth the number of concentrated barriers otherwise necessary but will require approximately the same quantity of rock dust as would be necessary if the zoning system alone were employed.

Little greater expense will be incurred in efficiently protecting a mine with rock dust applied in accordance with a well-established system than is now necessary in mines employing the imperfect and unsatisfactory method of dust watering.

Experience has shown that one of the greatest hazards to life encountered in the southern Illinois field is that arising from mine explosions. It is with a feeling of considerable satisfaction and gratification that a dependable means of safeguarding life and property against this danger has been developed. It merely requires that sufficient rock dust be properly installed before the explosion occurs. Disastrous results are thus rendered impossible.

Fig. 5—The Blower Distributor of Fig. 2

This gives a good idea of the simplicity of the mechanism. This machine as well as the other here pictured is used by the Phelps Dodge Corporation in its mines in New Mexico.

How Automatic Substation Equipments Operate And What Control Features Are Supplied

Kind of Automatic Switching Apparatus Depends Upon Requirements—
Starting Impulse May Be Given by Relay, Time Clock or Push Button
—Permits Location of Station Where Best Results Can Be Obtained

BY CHESTER LICHTENBERG
General Electric Co.

THE automatic power station is a new development in electric art. It was conceived by a central-station engineer and developed by a railway engineer. It is natural, therefore, for automatic stations to be more widely used in these branches of industry. Nevertheless, automatic substations seem equally available for the transformation and supply of electric power in other industries.

Electric power for factories, mills, mine shops and other industrial enterprises usually can be quite readily regulated by automatic devices. The kind of automatic switching equipment and its application, however,

the need to provide them with an operator has retarded their location at strategic points on the power-distributing network, or forced their location in existing attended stations remote from the point where they could do the most good. Whatever the reason may have been, the successful automatic operation of these units has extended their field of application widely.

The first automatic synchronous condenser was a 3,000-kva. unit installed by the Interstate Light & Heat Co. at Hazel Green, Wis. It was started in March, 1917, and is still in successful operation. It is located at a point on the transmission lines where regulation

Early Type Unit

This equipment is completely automatic, yet provision is made for manual operation. On the extreme end of the machine is the device for raising and lowering the brushes. It sets the brushes in position soon after the starting cycle is completed. This station is located at the Pleasant Hill Mine, of the Clearfield Bituminous Coal Corp.

depends to a large extent on the particular requirements of the industry.

Generally, some form of power-transforming equipment is utilized at all industrial plants. It may be rotating equipment such as motor-generator sets, synchronous converters or synchronous condensers, or it may be static equipment such as transformers, static condensers or mercury-tube converters. All of these have been equipped with automatic switching and control for central station, railway and mine service and can readily be adapted to other industries.

Primary generating plants using water power are particularly well-suited for automatic control, but steam-operated stations have not thus far been so controlled.

Synchronous condensers form one of the simplest classes of rotating machines to which equipment for automatic control has been applied. They also form a class of power conservers which industrial organizations seem hesitant to adopt. It may be that heretofore

had previously been quite poor. It more than paid for its cost in the first two years' operation. The latest automatic synchronous condenser is a 7,500-kva. unit being installed by the New England Power Co. at Worcester, Mass., mills of the American Steel and Wire Co. In the meantime there have been a number of installations of automatic synchronous condensers but invariably by the power companies, although in most cases the condensers have been utilized for the correction of power-factor conditions caused by the industrial enterprises using the electricity.

The automatic control of a synchronous condenser is relatively simple. The starting impulse is given by any one of several familiar devices. A voltage relay, a power-factor relay, a time clock or simple tumbler switch may be used to start the set. The synchronous condenser is usually provided with an amortisseur winding and is brought up to speed as an induction motor. A compensator or Y-delta starter may be used, either being readily adapted to automatic control. Usually during the period of acceleration, the synchronous condenser field remains disconnected from the

Note—Presented before American Institute of Electrical Engineers, Birmingham, Ala., April 10, 1924.

source of exciting current and is bridged by a field-discharge resistor. This aids in giving the required starting and pull-in torque. After its field is excited, the unit has been connected to the line and full pressure has been applied to its windings, it begins to function as a power-factor corrector. A power-factor or a voltage regulator which forms part of the automatic switching equipment adjusts the field current automatically to maintain either fixed power factor or fixed pressure within the limits of the unit.

Automatic synchronous condensers are provided with the usual automatic station protective devices. The bearings are equipped with bearing temperature relays which will cause the set to be shut down before damage results if the bearings tend to overheat. The machine armature is provided with current-operated thermal relays having a time-temperature characteristic similar to that of the condenser. These automatically shut down the machine if the armature current exceeds a safe value for a predetermined interval of time. They also permit the unit to re-start automatically after a shutdown of sufficient time duration to cool the windings. These thermal devices are of the integrating type and are self-adjusting for ambient temperatures.

A grounding protective relay is also provided which causes the set to shut down in case of any leakage to the ground in excess of 50 amperes. This device protects against insulation failures and prevents undue damage. Single-phase starting, harmful single-phase running, reverse phase, loss of field, too low line pressure, short time alternating-current overload, etc., are also prevented by the usual automatic station relays.

Synchronous motor-generator sets form the next general class of rotating electrical machines which have been successfully equipped with automatic switching. Units of 150-kw. capacity are now operating in many sections of the coal-mining districts and are typical of the smaller sizes. A 2,000-kw. set is in operation on the 666-volt direct-current electrification on the main line of the New York Central R.R. and is typical of the larger sizes applied to severe operating conditions.

These units may be started on load demand or at a pre-determined time by a clock or by a tumbler switch or its equivalent. The automatic switching equipment

proceeds to function immediately the starting impulse is given. First, it checks the line voltage to determine whether it is ample to start and run the set. Next, it checks the power supply to be sure all the phases are intact and are of the correct sequence. Then, it checks the bearings, machine windings and ambient temperatures, to be sure these will permit the machines to run if and when started.

Next, it connects the motor to the source of power, either through a compensator or directly to taps on the transformer, or through the transformers if Y-delta starting is used. Then the set starts to rotate and comes up to full speed. At synchronous speed, the automatic switching equipment again functions and connects the field circuit to the source of the exciting current. When the field current has been established, the set is transferred from the starting to the running circuits. During the accelerating period the motor field remains disconnected from the source of exciting current and is bridged by a resistor in the same manner as is the synchronous condenser during its starting cycle. This permits individual adjustment of each motor so as to obtain a complete start under practically all conditions which can be found in service.

In the larger sets, a low value of field is applied while on the starting tap, and the full value after the machine is transferred to the running connections. In the smaller sets, the full value is applied in one step while the machine is running on the starting taps. The smaller sets having 250-volt or 275-volt direct-current generators are usually excited directly from the generators. Those rated for higher pressures or arranged with voltage regulators are usually supplied from an exciter either separately operated or direct-connected.

The synchronous motor has the usual automatic station protective apparatus to prevent runaway, operation without field, harmful single-phase operation, leakage to ground, short-time and long-time continued overload, bearing temperature control, etc. Some of these devices, such as the bearing temperature relays are hand reset where continued operation of the machines under any circumstances might lead to their destruction.

The number of such devices, however, is a minimum so as to insure continuity of service under all conditions, excepting where the machine might fail or other

Provides Safe Operation

The automatic control of this station recently installed at Rimerton, Pa., by the Rimerton Coal Co., makes safe operation possible. Automatic devices will be adopted in future if for no other reason than because it assures safety to men and equipment.

Automatically Operated Motor-Generator Set

This 300-kw. synchronous motor-generator set was one of the first mine units to be changed from manual to automatic operation. The stack of rheostats, shown above the switchboard, limits the load which can be applied to the machine.

serious consequences may result. Most of the other protective devices, such as the long-time delay overload relays, phase-checking relays, etc., are automatically reset and permit the equipment to resume normal operation as soon as the unusual conditions have been corrected.

The direct-current generator is provided with protection and adjustment, depending upon the service requirements. The simpler machines which may be shunt or compound-wound, are usually operated with a fixed shunt-field setting. This setting is chosen to give the desired terminal pressure, and in the case of multiple-unit sets, must be carefully adjusted to give the correct loading of the machines. Multiple-unit stations also require careful compounding of the units to permit the successful multiple operation of "hot" and "cold" machines.

The direct-current generators of large-sized motor-generator sets are frequently provided with automatic load regulation. One type is provided with a shunt-field bucking scheme. This has been successfully applied to shunt-wound generators for multiple-pressure booster service. The shunt-field current is normally furnished by the generator itself.

The current is passed through the armature of a small motor-generator set continuously rotating. This set, by suitable increase or decrease of its field current, bucks or boosts the shunt-field current of the generator, the correct amount, and gives the desired regulation. In one example, using this method of control, load swings of from 300 per cent normal to 200 per cent reversal are successfully handled.

Another modification is a compound-wound direct-current generator with the series field connected to oppose the shunt field. This type of generator is usually operated with the series field shunted by a circuit breaker which allows only a fraction of normal current to flow through the field when it is closed. Under heavy overload conditions, the circuit breaker is automatically opened and the series field carries the full line current. As soon as the overload condition ceases, the circuit breaker automatically recloses and shunts the series field.

By suitably proportioning the shunt and series fields, the direct-current generator can be made practically a constant-current machine, and service may be maintained at a reduced pressure during emergency load conditions. A number of such equipments are operating on the Edison three-wire networks of many of the large electric power corporations, and their use is being rapidly extended. Their judicious application to electrified industrial establishments would insure continuity of service under the most severe conditions short of complete and sustained interruption of the primary electric power supply.

Synchronous converters form without exception the largest single class of rotating electrical machines which have been successfully provided with automatic switching equipment. In fact, they were the first electrical machines to be so equipped, notwithstanding the fact that with a single exception they are considered the most difficult electrical machines to operate. This is principally because of the almost universal application of synchronous converters for interurban railway service where automatic stations were first widely adopted.

An automatic synchronous converter may be started by any one of the usual devices, such as a pressure relay, a time switch or their equivalent. Immediately the starting impulse has been given, the synchronous converter is connected to the starting taps on the power transformer. One-third or one-half full-voltage taps, depending on the design of the synchronous converter and transformers will usually furnish sufficient torque to start the converter armature and pull it into step. Then the converter is automatically transferred from the starting to the running taps.

During the starting operation, the shunt field is usually opened. After the machine has reached synchronous speed, its field is either flashed with the correct polarity before it is made self-exciting or is reversed until correct polarity is established.

The next step is to connect the synchronous converter to the direct-current network or feeder system and here the inherent characteristics of the converter require a different series of operations from those

provided with motor-generator sets. The direct-current terminal pressure of a synchronous converter is regulated largely by the pressure of the alternating-current supplied. By the field adjustment the direct-current terminal pressure can be regulated only over a relatively narrow range.

This field adjustment, therefore, needs to be supplemented by some arrangement for safely connecting the synchronous converter to the direct-current network, even though that network may be operating at a pressure quite different from the terminal pressure of the synchronous converter. This condition is most usually encountered in all sorts of electric haulage installations, for in all of these the changes in power demand are large compared with the feeding capacity of the supply of alternating current.

USE OF LOAD-LIMITING RESISTORS

For electric railways and commercial electric power service generally, and sometimes for industrial electric power supply, synchronous converters are equipped with load-limiting resistors. These are connected between the direct-current terminals of the synchronous converter and the direct-current network or feeder after the synchronous converter has been brought up to speed and put in operating condition, in so far as the alternating-current side is concerned. These resistors are usually shunted out in two or three steps thus gradually loading the synchronous converter with the direct-current load.

The shunting contactors or circuit breakers used for this service are usually provided with current relays having interlocks, so that the synchronous converter cannot be loaded beyond its thermal capacity. Other devices such as thermostats, located near the load-limiting resistors, permit the synchronous converter to supply current to the direct-current system within safe heating limits. The current is allowed to continue so long as the critical temperature is not reached. In many cases the reduction of the load prevents that point being attained but should the load continue heavy enough the thermostat comes into operation before the resistors and converter heat to a dangerous

degree. Should the thermostat, however, be obliged to act the converter is automatically shut down until it and the resistors cool. After the equipment has cooled sufficiently, it is again automatically started and placed in service. In some cases, where economy in design and manufacture permit Y-delta starting, the load-limiting resistors are shunted out in only one step. With this combination and with suitable transformer design, the Y-delta arrangement may be used to take the place of one step of the load-limiting resistors.

The load-limiting combination available for, and used with, synchronous converters permits their wide application to all electrified industries. It permits the use of the economical synchronous converter in many places where motor-generator sets were formerly considered most desirable. For certain few applications, they are excelled only by specially designed motor-generators with automatic load-regulating features.

Synchronous converters for automatic operation are provided with the usual automatic-station protective features such as bearing and resistor temperature relays, short and long-time continued alternating-current overload relays, single-phase starting and harmful continued single-phase running preventive relays, low alternating-current pressure starting or operating preventive relays, overspeed switches in combination with a shunt trip circuit breaker, leakage to ground relays, etc.

Other electric power-transforming machines, such as balancers, mercury-tube converters, and static transformers have been made completely automatic and equipments thus protected are now in successful operation. Their design is usually patterned after the best manual-operation scheme, except that the time for the switching is generally reduced from minutes to a few seconds.

Feeder breakers on alternating-current and direct-current networks are now not only automatically tripped on overload, but also automatically reclosed when conditions are correct and safe. Many such protective systems are available, each being particularly designed for its individual application.

Rotary-Converter Outfit

Ordinarily automatic equipment appears to be extremely complicated. However, this station was installed and put in operation by the Black Diamond Coal Co., Drakesboro, Ky., in much shorter time than that usually required to install a manually operated station.

News Of the Industry

Republican Platform Adopted at Cleveland Has Broad Bearing on Coal Industry

Conciliatory Attitude Toward Labor Seen in Planks Reaffirming Collective Bargaining and Opposing Compulsory Arbitration—Coal Plank
Lifted from One of President's Addresses

BY PAUL WOOTON
Washington Correspondent of *Coal Age*

Cleveland, June 13.—The coal-mining industry is concerned with more than the coal plank which just has been indorsed by the Republican National Convention. The declarations in the labor plank and the labor section of the railroad plank are of greatest importance to the coal industry. Briefly these planks reaffirm collective bargaining and intimate that the function of the Railroad Labor Board should be modified, and the point is brought out unequivocally that the party "does not believe in compulsory action at any time in the settlement of labor disputes." This puts the party on record against compulsory arbitration and in doing so accepts one of the more important declarations of the Harding Coal Commission, which could not see its way clear to recommend compulsory settlement of disputes.

Platform's Labor Planks

The attitude of the platform toward labor is conciliatory. This attitude is emphasized by the favorable reference to the child labor amendment, which long has been sought by the American Federation of Labor. At first glance it appears that the party managers have attempted to placate the United Mine Workers, among others of the powerful unions, but it is doubtful whether the utterances amenable to such an interpretation will impress the miners as much as that section of the coal plank which says, "When, through industrial conflict, the supply is threatened, the President should have authority to appoint a commission to act as mediators and as a medium for voluntary arbitration." The mine workers of late have felt so strong that they have disdained mediation except in an instance or two when they felt themselves in danger of losing.

The reaction among some of the political observers in Cleveland is that the labor vote will be influenced less by the professions of the platform than by the past utterances of the candidates. Since assuming the office of President Mr. Coolidge has done nothing which has incurred the enmity of labor leaders unless it be the veto of the postal salary increase. His policy in the Boston police strike at that time

made him anathema to labor leaders.

As for General Dawes, labor is expected to look upon him as being upon the side of the employers. It is quite apparent that the Republican candidates will not be indorsed by the American Federation of Labor. It is doubtful, however, that any candidate that the Republicans might have chosen could have obtained the indorsement of that body and it has been demonstrated again and again that while the American Federation of Labor acts unitedly in such matters as wage demands, it is unable to deliver labor's votes. In a political campaign impressions are made by individual candidates upon individual workers.

The coal plank as it stands is practically lifted from one of the President's messages to Congress. It embodies the same ideas and expresses them in practically the same words. It commits the party to full publicity of the kind foreshadowed by Senator Oddie's references to the coal bill which he partly prepared but which he did not introduce.

To Probe Labor Disputes

The plank commits the party to investigations of all labor disputes by special representatives of the President and commits the party to federal control of distribution during any period of shortage of supply. The precise means of obtaining those ends are not set forth but on the whole the plank is an acceptance of the major point in the Coal Commission's report.

The platform, with its commitments in regard to the World Court, and the selection of General Dawes as Mr. Coolidge's running mate mean participation in Europe affairs. In the matter of farm relations it is apparent that the party has materially altered its policy. The party has not only underwritten the World Court but it has underwritten the Dawes reparation plan. By giving its moral support to these two endeavors, the Republican Party has entered into world affairs just as definitely as would have been the case had it indorsed the League of Nations. This seemed to be the opinion of the majority of the delegates to the convention, even though they did not like to admit it.

Coolidge's Coal Plank

The Republican presidential platform adopted by the convention at Cleveland, June 11, contains the following "plank" on coal:

"The price and a constant supply of this essential commodity are of vital interest to the public. The government has no constitutional power to regulate prices, but can bring its influence to bear by the powerful instrument afforded by full publicity.

"When through industrial conflict its supply is threatened, the President should have authority to appoint a commission to act as mediators and as a medium for voluntary arbitration. In the event of a strike, the control of distribution must be invoked to prevent profiteering."

In the selection of General Dawes the party virtually agrees to uphold his hands in the reparations agreement which he effected. This means the moral support of the party for the securities of the bank which the Dawes report proposes, which must be sold largely in the United States. The party has taken action which tends to approve the contention of Ramsay MacDonald, the British Premier, that isolation declarations on the part of the United States are "pompous folly." The Democratic Party favored rushing into the League. Four years ago the Republican Party held aloof from any definite commitments as to foreign relations. Apparently now it has adopted a middle course between these extremes.

All of this has a bearing on coal. If it stimulates rehabilitation in Europe our prosperity will be stimulated, particularly in the agricultural regions, thereby removing one of the sores on the body politic. To reduce the amount of discontent and to bring about a more stable business situation means the consumption of more coal. By increasing the ability of Europe to buy, our export trade will be increased, and that means that more coal must be consumed.

The platform again touches coal in its indorsement of immigration restriction. This means that the great stream of recruits from whom mine workers once were made will not be restored. The mines will have to bid for labor in competition with other industries. This will help to maintain the present level of wages and pave the way for increases when new levels of prosperity have been reached.

Study and Fun Mark Three-Day Outing Of Illinois Mining Institute

**Causes and Remedies of Explosions, Cleaner Coal, Radio Communication
Between Mine and Surface and Safety Training Come in for
Discussion on Mississippi River Cruise**

Special Dispatch to Coal Age

Ninety Illinois mining and machinery men spent three days cruising the Mississippi between St. Louis and Paducah, Ky., on the new stern-wheeler "Cape Girardeau" last week enjoying a real vacation full of good fellowship and discussion of mine problems. It was the eleventh annual summer outing of the Illinois Mining Institute. The boat left St. Louis the night of June 12, and returned the morning of the 15th.

A right good outing it was, too, mingling horseplay with studiousness, fair weather with a midnight Mississippi hurricane, calm moonlight drifting with a race against the "Tennessee Belle," and languorous hours on deck with a vigorous visit at the new plant of the Atlas Powder Co., 12 rough miles back from the landing at Grand Tower, Ill. Many of the men saw river sights new and entertaining to them, they all enjoyed the hospitality of Paducah, Ky., and Cape Girardeau, Mo., where they were driven about in automobiles, and they landed at St. Louis Sunday morning, June 15, with memories to cherish until next summer.

Variety of Papers Read

The program was administered in short doses in the main saloon of the boat except for one afternoon session on the forward deck. President D. D. Wilcox and Vice-President Ted Lewis presided. Causes and some remedies of explosions were treated by L. D. Tracy, superintendent of the Bureau of Mines station at Urbana, Ill. Martin Bolt, director of the Illinois Department of Mines and Minerals, proposed some methods of reducing accidents. A paper by Arthur M. Hull, appealing to operators to produce cleaner coal, was read, and S. W. Farnham, mining engineer for the Goodman Manufacturing Co., was most entertaining in his illustrated talk about primitive coal mining in India. Something new was sprung by A. B. McCall, of the Springfield (Ill.) High School faculty and consulting engineer for the Bureau of Mines. He announced that the radio club of the high school, on which he keeps a guiding hand, had established radio communication between mine and surface by vertical conduction of voice currents through the ground. This has never been done before, he said.

Harold C. Culver, of the Illinois Geological Survey, told the Institute of a general Illinois coal report soon to be issued and asked for suggestions as to material mining men thought should be in it. The discussion of the institute centered on safety mainly.

An appeal for cleaner coal was made by Arthur M. Hull, editor of the *Midwest Coal Retailer*, in a paper read by Frank M. Tirre, of St. Louis. Mr. Hull pointed out that only 20 lb. of bone in a ton is 1 per cent and that often the percentage of unnecessary ash shipped

with coal runs up to 30 and 35, all of which takes the full coal freight rate and helps to make the consumer disgusted not alone with the dealer who sells it but the operator as well. This sort of thing is responsible for part of the loss of market to oil producers. The miner ought to be convinced that had he always loaded out clean coal fewer mines would be shut down nowadays and fewer men would be jobless, the paper said.

Two heated arguments were started by Martin Bolt's discussion of accidents in Illinois—the old ones about whether the British miner is safer than the American and whether the Illinois com-

Dr. George Otis Smith

Director of the U. S. Geological Survey, who will represent the United States as a delegate to the world power conference at London, June 30-July 12.

pensation law is a help or a detriment. Both went 10 rounds to no decision as usual.

Scanning 40 years, he said in the first eleven years the ratio of deaths was 2.7 per thousand men employed and 4.1 per million tons produced. Accidents causing the loss of 30 days or more working time were 8.8 per thousand men and 17.6 per million tons. During the next decade, when machinery and electricity came in, deaths per thousand dropped from 2.7 to 2.3 and non-fatal accidents per million tons declined from 4.1 to 3.8. From 1904 to 1913, when gigantic mines were built and tonnage doubled, the fatality rates per thousand men rose to 2.9 but accidents decreased from 13 to 10.2 per thousand men and from 22.3 to 15 per million tons. Then came the compensation law period. Between 1913 and 1923 deaths decreased from 2.9 to 2.2 per thousand men and from 4.2 to 2.6 per million tons while non-fatal accidents jumped from 10.2 to 28.6 per thousand men. Exactly 62.5 per cent of all the non-fatal accidents

of the whole 40 years took place in that period.

He said 60 per cent of all Illinois accidents are due to falls of roof and coal and to mine cars and motors and that therefore attention ought to be centered on them. The industry should not accept the tremendous accident total as "just part of the business," but should regard mining as a most dangerous occupation, as in England, and hedge it about with more intense safety effort. He advocated making safety part of every miner's training, the adoption of a strict safety code and the rigid enforcement of this code, not by the employer alone but by a joint board of miners and operators.

While the ensuing arguments were rollicking gayly along some things of interest also were said. D. D. Wilcox declared greater safety and greater production go hand in hand and that he always has observed in his own company that attention to safety means more economical and intelligent operating methods. In one mine, where a manager made a special safety effort, not a single accident occurred in 30 days and production went up 20 per cent. A great deal was said by various members about how the compensation law enables crooked miners to collect from their employers for all sorts of questionable accidents; yet president Wilcox was cheered when he appealed to companies to "be fair minded toward the men and the majority will be fair minded toward the companies." He thinks there must be more underground supervision, for today it is all but impossible for a boss to see each of his 75 or 100 men more than a minute or two a day.

Would Train Miners in Safety

L. D. Tracy argued for safety training for every miner. Men who have taken it are seldom hurt. A. B. McCall suggested that safety training be required before any man gets a certificate. Frank Tirre said great safety effort can be made through such organizations as the Superintendents and Managers Association of the Fifth and Ninth Illinois districts, to which 77 men now belong and meet regularly to discuss every sort of operating problem with very personal interest. The fact that these men visit each other's properties and discuss them critically at the meetings stimulates a lot of effort at the mines out of a sense of pride. C. J. Sandoe, a general superintendent, found that accidents were reduced so much merely by requiring detailed reports of every one from mine managers that insurance rates were lowered.

No company should ever let its men get the idea that it doesn't care much if they get hurt, according to J. H. Haskins. Real interest in safety by one company he knows of permitted that company to run two years and produce two million tons of coal without a major accident.

Tom Hunter argued that accidents certainly would be reduced if shotfirers all set their own shots. One thing the whole Institute agreed upon was that where there is good feeling and mutual interest between men and companies, accidents are reduced and that there is no better way to reduce them than to develop such good feeling.

Coal Contracts Awarded for New York Institutions

The Shawnee Fuel Co., of New York City, was awarded contracts for furnishing and delivering to various New York State institutions 82,000 net tons of run of mine coal, as a result of bids opened May 27 by the State Department of Purchase at Albany. The prices ranged from \$1.45 to \$1.69 per ton f.o.b. mine. This company also obtained the contract for furnishing and delivering 2,000 net tons of slack coal to the Binghamton Hospital at \$1.99 per ton f.o.b. mine. Deliveries on all contracts are for the period between July 1, 1924, and March 31, 1925. Other contracts awarded follow:

Titan Fuel Corporation, New York City, 25,600 tons run of mine to the Central Islip Hospital and 3,600 tons to the Kings Park Hospital, Long Island, at \$1.48 per ton f.o.b. mine; George D. Harris & Co., New York City, 360 tons run of mine to Farmingdale (L. I.) Hospital and 800 tons of smokeless coal to the Willard Hospital at \$1.48 and \$1.69 per ton, respectively; E. L. Hedstrom, Buffalo, 400 net tons 14-in. lump to Fredonia Normal School at \$2.15 per ton, f.o.b. mine; Hartmann Coal Co., New York City, 28,120 net tons run of mine to various institutions, \$1.65 per ton f.o.b. mine; W. G. Morton, Albany, 3,360 tons run of mine to Matteawan State Hospital, \$1.47 per ton f.o.b. mine; George H. Foster Coal Co., Pittsburgh, Pa., 4,160 net tons nut and slack at \$1.30, and 400 net tons three-quarter lump, \$1.70 per ton f.o.b. mine; and Commercial Coal Co., New York City, to institutions in New York City, 7,200 tons run of mine, \$4.24 per ton, f.a.s. dock; 13,600 tons run of mine, \$4.29 per ton, f.a.s. dock, and 600 tons slack, \$3.96 f.a.s. dock.

For furnishing and delivering 500 gross ton broken coal, 1,650 tons egg, 4,290 tons stove, 1,545 tons chestnut, 5,900 tons pea coal, 10,000 tons No. 1 buckwheat, 20,000 tons No. 2 buckwheat

Upholds I.C.C. Ruling in Joint Mine Case

The order of the Interstate Commerce Commission regulating the distribution of cars among soft-coal mines located on two or more railroads was approved by the U. S. Supreme Court in a decision handed down June 9. The effect of this ruling is to limit the number of cars that a mine located on and served by more than one railroad may order to 100 per cent of its rated capacity. Prior to this decision a joint mine was permitted to order 150 per cent of its rated capacity.

The New River and other companies operating bituminous-coal mines in West Virginia succeeded in the lower federal courts in having annulled the order of the commission which applied to mines located on two or more railroads, a rule with regard to car distribution different from that applying to mines reached by only one road.

Ira C. Cochran

Reappointed commissioner of the American Wholesale Coal Association at its recent convention at White Sulphur Springs, W. Va.

and 10,000 tons No. 3 buckwheat to various institutions the D. L. & W. Coal Co., New York City, was awarded the contract at the May circular price, subject to an increase of 10c. per month to Oct. 1 and a decrease in April next, deliveries to be made between July 1, 1924, and June 30, 1925.

Martin F. Shea, of New York City, was awarded the contract for delivering 700 tons of egg coal, 11,590 tons stove coal, 1,590 tons chestnut, 39,900 tons No. 1 buckwheat and 200 tons of grate coal to other institutions at \$2.64 f.o.b. mine for the buckwheat, \$8.85 for stove and \$8.75 for chestnut and grate.

Lewis Suspends Autonomy of West Virginia Union

The International Executive Board of the United Mine Workers on June 14 suspended the autonomy of District No. 17, which includes practically all of West Virginia, and Percy Tetlow, of Ohio, was named head of the district by John L. Lewis, International president of the union.

Headquarters for Mr. Tetlow will be established in Charleston, W. Va., and he announced that Van A. Bittner, of Pittsburgh, International representative, would be placed in charge of the northern part of the district, with headquarters at Fairmont. The order became effective June 16.

That policies of the International union had not been applied and enforced with sufficient vigor in District No. 17 was given as the reason for the suspension. It also was explained that all of the district and subdistrict officers of the union in West Virginia appeared before the Executive Board and filed a petition asking that the International union assume charge.

Union policies hereafter will be pursued vigorously in West Virginia and "differences of opinion among the former district officials resulting in conditions menacing to the union will be eliminated," according to an announcement at union headquarters.

Operators and Engineers to Study Mine Safety

More than 200 coal-mine operators and mine safety engineers will meet in a Midwest coal-mine safety conference called by the Mining Section of the National Safety Council at St. Louis, June 25 and 26.

The tentative program is as follows: Wednesday, June 25, 10 a.m., "Prevention of Haulage Accidents," Ralph D. Brown, superintendent O'Gara Coal Co., Harrisburg, Ill.; "Mine-Rescue Work in Illinois," by a rescue-station superintendent; 2 p.m., "Ventilation and Dust Control," J. E. Jones, Old Ben Coal Corporation, Chicago; "Safe Handling of Explosives," by a powder company man. Thursday, June 26, 10 a.m., "What the Joseph A. Holmes Safety Association Is Doing for Accident Prevention"; "Getting Results from Organized Safety Work," C. L. Colburn, U. S. Bureau of Mines, Pittsburgh; 2 p.m., "Mine Gases and Their Effect on the Body," Dr. H. G. Bristow, professor of chemistry, St. Louis University; "Infections from Wounds," Frank Farrington, district president of the miners' union of Illinois, will lead the discussion of Mr. Colburn's paper.

Gilbreth, Efficiency Expert, Dies in Telephone Booth

Major Frank B. Gilbreth died suddenly from heart disease Saturday, June 14, in a telephone booth of the Lackawanna R.R. Major Gilbreth was one of the first to take an interest in motion studies in their relation to efficiency of operation. He was born in Fairfield, Me., in 1868 and was a contracting engineer in Boston from 1895 to 1904 and in New York until 1911, when he became a consulting engineer. In 1917 he was made consulting major of engineers in the U. S. Army and was on active duty at the general staff college at Washington. He organized the Taylor Society for the promotion of the science of management.

Union Demands Dismissal Of Town Officials

A bombshell was tossed into the town of Sydney Mines, one of the leading bituminous coal mining centers of eastern Canada, when Jubilee Local of the United Mine Workers demanded of the Town Council that every official of the town be dismissed. The order was signed by the president and secretary of Jubilee local, which has headquarters in Sydney Mines. It is charged that the officials of the town, from the Mayor down, favored the operators, and discriminated against the Communist leaders of the union for the eastern Canada district. Dire threats were made in the event that the order was not heeded. Some time ago the Council of New Waterford, another mining center, dismissed the entire fire department because members played cards and checkers with executives of the Dominion Coal Co.

Rock Dusting Lowers Insurance Rate

Gas and Dust Explosions Have Killed Nearly 6,000 Men—Insurance Cost Would Have Been \$14,000,000 at Present Rates—Explosion Risk May Be Lowered 85 per Cent

By G. B. BUTTERFIELD
General Manager Associated Companies,
Hartford, Conn.

Owing to the increasing frequency of explosions in coal mines during the winter of 1923 the compensation insurance carriers have made an exhaustive study of the causes of mine explosions.

They found that in the United States from 1839 to 1923 inclusive 7,907 men were killed in bituminous mine disasters. Of this number 5,722 men, or 72 per cent, lost their lives in gas and coal-dust explosions. If workmen's compensation laws had applied to all of these explosions, the compensation cost alone, at the average of \$2,500 per death, would have been \$14,305,000. This is an enormous loss measured in dollars, to say nothing of the families which were deprived of their supporting heads by these preventable explosions.

The U. S. Bureau of Mines' experiments verify the fact that if rock dust and bituminous-coal dust are mixed in such proportions as to have a mixture of about 45 per cent coal dust and 55 per cent rock dust, the coal dust will not explode. Coal mines can be rock-dusted by hand, but this is rather ineffective and expensive. The best way to rock dust a mine is with the use of mechanical equipment and in many mines home-made equipment is doing the work quite satisfactorily. A small motor mounted on a track drives a centrifugal fan, which forces the rock dust through a nozzle, and on the end of the nozzle there is a sphere filled with small holes through which the rock dust is forced with much pressure. This sphere is held in a fixed position, thus insuring the complete spraying of the roof, ribs and bottom.

Mine Dust Should Be Tested

In specifically ascertaining the time when the mine should be rock dusted again, certain areas of the dust at various places in the mine should be tested. A mine official should select an area about 8 in. in width across the roadway and take samples over this section—one from the roadway, one from the ribs and one from overhead on the roof or timbers. These samples should then be run through a ten-mesh sieve and that portion of the sample which will not go through the sieve should be rejected; the remainder is the sample which should be tested for the percentage of combustible content. A simple machine known as a volumeter has been invented and placed on the market for this purpose.

The leading coal-mine compensation insurance carriers recognize the rock dusting of bituminous-coal mines as a real safety factor in the prevention of mine explosions, and have incorporated this subject as Item 1-C in the Bituminous Standards. The specific wording of this paragraph is as follows:

"All entries, aircourses, manways, room necks and entries or approaches

(other than old room necks to old and abandoned sections, shall be rock dusted with limestone, shale or other inert dust approved by the U. S. Bureau of Mines. The application shall be of sufficient amount and of sufficient frequency to maintain on the roof, ribs, bottom, timbers and all places of lodgment sufficient inert dust so that the combustible content of the resulting mixture of rock dust with coal dust shall not exceed 45 per cent at all times. That is, the resulting mixture of rock dust with coal dust shall not exceed 45 per cent of coal dust, allowing the remaining 55 per cent to be rock dust."

Reduced Rates for Good Records

The insurance carriers have decided to allow a reduction in rate varying from 10c. to 20c. per \$100 of payroll, depending upon the past history of catastrophes in each specific state.

The compensation insurance carriers are so sincere in their belief in the good results to be obtained by rock dusting that they feel that approximately 85 per cent of the deaths in mine explosions would be averted if the mines are rockdusted.

Let our motto be "That every bituminous coal mine in the United States be rock dusted before Oct. 1 of this year."

Lewis to Probe Anthracite Outlaw Strikes

Special Dispatch to Coal Age

Scranton, Pa., June 16.—John L. Lewis, International president of the United Mine Workers, is to conduct an investigation into the series of outlaw strikes affecting collieries and coal companies in the Pittston region of the anthracite field. To this end he will send five international organizers to the field. Yesterday, following the receipt of telegrams from President Lewis, the general grievance committee of the Pennsylvania and Hillside Coal & Iron Co. strikers, numbering 11,400, who have been idle the past week, voted to return to work on Tuesday morning. Much opposition to the motion was encountered from the radical elements on the committee. It is possible that the International office investigation will get under way this week and before it is ended many of the radical powers in the local organization may be dethroned.

Horace M. Swetland, Noted Publisher, Dies

H. M. Swetland, president of the United Publishers Corporation, which publishes *Iron Age*, *Dry Goods Economist*, *Automotive Industries* and other important business publications, died at his home in Upper Montclair, N. J., June 15. He was one of the pioneers of modern industrial publishing and had been a leader in raising journalistic standards through his activities in the Associated Business Papers. At one time he was owner of *Power* and of *Engineering & Mining Journal* (as it was then called), both now owned by the McGraw-Hill Company.

Mr. Swetland was born in Chautauqua County, New York, in 1853. In 1880 he came to New York as reporter and as subscription and advertising salesman of the *Boston Journal of Commerce*. In 1884 he became Boston representative of *Power*, later coming to New York and assuming the management of that publication. In this capacity he was associated with James H. McGraw, now president of the McGraw-Hill Company, and Emerson P. Harris. The association was discontinued in 1888 when Mr. Swetland purchased *Power*, the ownership of which he retained until he sold it to the late John A. Hill in 1900.

In 1911 he organized the United Publishers Corporation, which included publications in the steel, automotive, building and textile fields. He was elected president of that corporation and retained that office to the time of his death. He also was president of the National Publishers Association, the Class Journal Company, the Federal Printing Company, the U. P. C. Realty Company and the Swetland Realty Company, and a director of the Commercial Trust Company.

Mr. Swetland's work and contribution to industrial publishing are well set forth in the following tribute paid to him by his lifelong friend and former associate, Mr. McGraw:

"Mr. Swetland's success as a man and a publisher was due to a rare combination of personal qualities and business acumen. He was a tireless worker, had great penetration, concentration and perseverance. He was an organizer of the first rank and was always a co-operator. His ideals in publishing were high, service to the readers of his publications being his first consideration. The publishing business has lost an outstanding figure in the passing of Horace M. Swetland, but his work will endure in the great institutions to which he gave unstinted devotion, and in the lives of those whom he trained in the technique of publishing and encouraged to make the best of their opportunities."

The Circuit Court, sitting at Fayetteville, W. Va., on Monday last, nolle prossed all indictments against C. Frank Keeney, Fred Mooney and William Blizzard, in connection with the armed march in Logan County in 1921. It was indicated that the efforts of the state would now be directed to the prosecution of active participants in the march.

Accidents at Coal Mines
During April Resulted
In Death of 234 Miners

Accidents at coal mines during April, 1924, caused the death of 234 men, according to the U. S. Bureau of Mines. The fatality rate for the month was 6.44 per million tons of coal produced, as compared with 7.06 for the previous month, 3.71 for April last year and 4.94 average for April during the 10 years 1914-23. The high fatality rate for April, 1924, was due to the Benwood explosion, on the 28th, which resulted in the loss of 119 lives. The rate for bituminous mines alone was 6.91 per million tons (including the Benwood disaster), as against 3.48 for April last year and 4.67 average for April for 10 years. For anthracite mines alone the rate was 4.41 per million tons, as compared with 4.96 for April, 1923, and a 10-year average rate of 6.28. Of the 234 men killed in April, 1924, 30 were killed at the anthracite mines in Pennsylvania and 204 at bituminous mines throughout the country. Underground accidents at both classes of mines numbered 220, shaft accidents 4, and surface accidents 10.

During the first four months of 1924 the records show a total of 993 lives lost, indicating a death rate of 5.06 per million tons. For the same period last year the rate was 4.08. The 4-month average rate for bituminous mines alone was 5.03 in 1924 and 3.84 in 1923; for anthracite mines alone it was 5.19 in 1924 as compared with 5.36 in 1923.

"Major disasters"—that is, disasters in which 5 or more lives were lost—

World's Highest Mine

The height of mines is not ordinarily as much of a factor as the depth. However the developers of the new Black Diamond mine of the Black Diamond Fuel Co., in the Clear Creek region of Utah, claim their mine holds the palm for height. It is 9,500 ft. above sea level, which makes it the most exalted coal mine in this country and probably in the world barring only a mine or two in the Crested Butte field of Colorado. But this is conveniently counted out because the coal mined there is not bituminous.

numbered five during the period Jan. 1 to April 30, 1924; the resulting loss of life was 384. During the corresponding months last year there were four similar disasters with a loss of 140 lives.

Comparing the causes of the fatal accidents in 1924 to the end of April with those for the same period in 1923, the records show reduced fatality rates attributable to falls of roof and coal, haulage equipment, explosives and electricity. Increased rates are shown for explosions of gas and coal dust. The following figures indicate the fatality rates per million tons for the main causes of fatal accidents at coal mines:

	Year 1923	January 1923	to April 1924
Falls of roof and coal.....	1.807	1.808	1.756
Haulage.....	.644	.649	.534
Explosions of gas or coal dust.....	.580	.770	2.082
Explosives.....	.177	.185	.142
Electricity.....	.117	.106	.082

Coal Contracts Awarded for
Navy Yards and Stations

The Navy Department awarded contracts June 10 for the supply of 221,150 tons of bituminous coal for use at navy yards and naval stations during the next fiscal year as follows:

Brinker Coal Co., Johnstown, Pa., 2,000 tons, for delivery at Iona Island, at \$5.30 per ton; 28,000 tons, for delivery at Indian Head, \$5.49.

Castner, Curran & Bullitt, Inc., New York, 5,500 tons, for delivery at Chelsea, Mass., at \$6.30 per ton.

Dexter & Carpenter, Inc., New York, 1,050 tons, delivered at Bellevue, \$4.63.

Hall Bros. & Co., Inc., Baltimore, 450 tons, for delivery at Fort Mifflin, Pa., \$4.90; 1,200 tons at Annapolis, \$6.05; 2,500 tons at Annapolis, \$4.96.

W. M. Hollerback, Philadelphia, 12,500 tons, Lakehurst, \$5.27.

W. C. Huber & Co., Philadelphia, 1,800 tons at Lake Denmark, at \$6.15.

Johnstown Coal & Coke Co., New York, 1,500 tons at Yorktown, Va., \$4.82.

Lake & Export Coal Sales Corporation, Chicago, 5,500 tons at Great Lakes, \$2.24; 34,500 tons bituminous screenings at Great Lakes, \$1.60.

Morrisdale Coal Co., Philadelphia, 30,000 tons at Philadelphia, \$4.54 under chutes and \$4.69 at wharf.

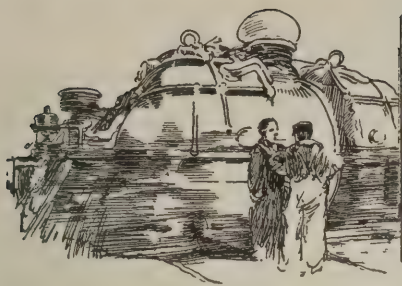

Pocahontas Fuel Co., Inc., New York, 5,500 tons at Portsmouth, \$5.03; 4,000 tons at Charleston, \$5.42.

L. A. Snead Co., Washington, 400 tons at Alexandria, \$4.95; 21,000 tons at Hampton Roads, \$5.03; 25,000 tons at Norfolk, \$5.03; 50,000 tons at Washington, \$4.90.

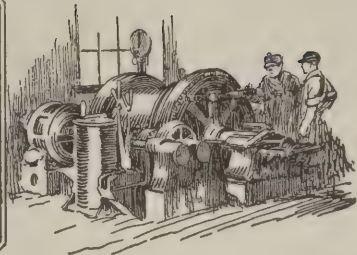

Coal-Mine Fatalities During April, 1924, by Causes and States

Practical Pointers For Electrical And Mechanical Men

Making Electric Equipment Safe to Use

Rife with suggestions for the prevention of accidents from electrical apparatus are the practices of the Union Pacific Coal Co. contained in an article by D. C. McKeehan, chief engineer, in a recent issue of the magazine published by that company.

He states that automatic starters are being installed for all motor-driven fans as part of the electrical safety program. Experience with these starters has shown that minor interruptions in the power circuit have no effect on the mine ventilation as the fan automatically starts when the current is restored. In the day or during the night reliance may be placed on these starters. They will do their work with almost human intelligence.

For example, power interruptions for, say, an interval of five minutes which may occur perhaps at midnight when few are around will not necessarily cause the fan to stand idle and the mine to go unventilated awaiting the next morning when someone will arrive who will set it in motion. With such an automatic starter the fan will "get busy" as soon as the power is restored.

Automatic reclosing circuit breakers have been in use for several years. Originally they were intended for the protection of generators against excessive currents and short-circuits. The Union Pacific Coal Co. is using them to sectionalize parts of the mine so as to limit the power that may flow into a short-circuit or a faulty piece of apparatus, and also to withhold power from defective locomotives or mining machines and thus not delay the whole mine pending the location of the faults, which are given the best of in-

A Fan That Will Not Be Idle When Power Is Available

Automatic starters on fan drives obviate the necessity for sending a man to the fan house to restart the motor after a power failure. If the voltage is taken off the line during the night and the fan remains idle until morning, large and dangerous accumulations of gas may result and cause explosions.

trouble. Have you thought of this as one of the functions of the automatic circuit breaker available for your mine?

In the near future all underground transformers in the Union Pacific Coal Co.'s mines will be installed in fireproof vaults so constructed that in case flame issues from a burning transformer the ignited transformer oil and insulation will cause a steel door to close and cut off the current to the transformers. The threshold to these vaults will be raised so that in the event of a transformer exploding the burning oil will not flow from the room.

In many instances the Union Pacific Coal Co. is no longer reducing the voltage from 2,200 volts to 220 volts but is carrying the higher voltage direct to the larger motors. The engineers have long realized that the 2,200-volt cir-

culation and protection, are much safer than the transformers which also require a 2,200-volt supply. Of the two evils, the transformers are regarded as the greater.

However, the use of 2,200-volt apparatus underground is not practiced without certain dangers that cannot go unheeded. First, these circuits carry high power and it is imperative that the protecting oil circuit breakers trip, that is, disconnect the lines, at times of trouble. Second, there are dangers if the metal parts containing 2,200-volt conductors are not properly grounded. This includes the motor frames, oil switches, relays, compensators, starting and controlling apparatus and all parts that may come in contact with 2,200 volts due to breakdown of the insulation.

It has been the intention of the Union Pacific Coal Co. for many years to ground all parts that high voltage may make dangerous, but as the machinery is removed to different parts of a mine or to different mines such matters are often overlooked, and it is necessary that all workmen become vigilant for their own safety as well as for that of others.

An object is protected by grounding when it is connected to the general mass of earth in such a manner as to insure at all times an immediate discharge of electrical energy without danger.

Men working on high-voltage lines short-circuit all conductors so that the switch or breaker will "kick out" in case it is accidentally closed. They, however, often neglect to ground the circuit as well as short-circuit it and this may bring about an extremely dangerous condition.

Although a 2,200-volt system may be free of ground yet there always exists a potential from either line to the

Electric Mine Lamps Reduce Fire Hazards

Nothing has contributed more than the electric safety lamp to make the work of the miner safer and easier. Sparks and smoke from the old-fashioned oil lamps were a continual source of danger. Oil-soaked clothes and timber were also responsible for serious burns and mine fires.

earth. The condition becomes dangerous if only one line is charged or one side of the circuit closed, as the voltage to ground would be dangerous to one working on either line and at the same time touching the earth.

Grounding is also resorted to in order to protect one from being subjected to a voltage to the earth that is higher than the normal voltage of the circuit.

Suppose a transformer breaks down and allows the 2,200 volts to come in contact with the 110-volt secondary. We would then have a voltage of 2,200 to earth, but, by grounding one side of the 110-volt circuit, in most cases, a voltage higher than 110 volts to earth cannot exist and the high voltage cannot manifest itself in a dangerous way.

Phasing Out a Converter

Before starting any converter for the first time if it is necessary to predetermine the direction of rotation a test of the wiring should be made to insure that the connection of the incoming line phases to the machine rotate in proper sequence. With each start by an induction-type starting motor or from the direct-current side some method for indicating synchronism between machine and line is also necessary.

The elementary principle of the method of determining when two alternating-current machines are of the same frequency and are in phase is illus-

Fig. 1—Connections Used When Synchronizing Circuits

The diagram shows the wiring of the lamps when synchronizing two single-phase circuits. When the voltage of the two circuits are exactly equal and in phase the current in the lamps is zero. Under this condition there is a balance of the two opposing pressures at the terminals of the lamps.

trated by Fig. 1 in which A and B represent two single-phase machines, the leads of which are connected to the busbars by the switches C and through two series of incandescent lamps. It is evident that as the relative positions of the phases of the voltages change from that of exact coincidence to that of exact opposition, the flow of current through the lamps varies from a minimum to a maximum. If the voltages of the two machines are exactly equal and in phase the current through the lamps will be zero and, as the difference in phase increases, the lamps will light up and will increase in brilliancy until the maximum is reached when the phases are in exact opposition. From this condition they will decrease in brilliancy until completely dark, indicating that the machines are again in phase. The rate of pulsation of the brilliancy of the lamps depends upon the difference in frequency; i.e., in the speeds of the machines. In cases of

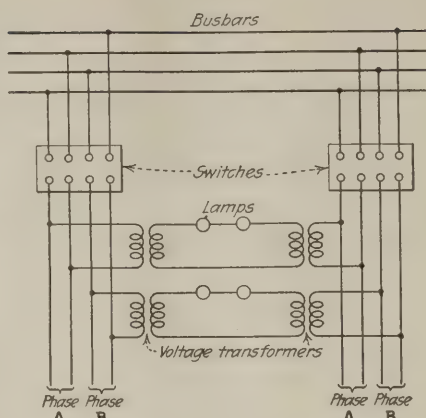

Fig. 2—Two-Phase Testing

By reversing the connections of one of the primaries or one of the secondaries of the transformers dark lamps will indicate synchronism if bright lamps had previously indicated synchronism. Smoother results are generally obtained when paralleling circuits if synchronism is indicated by the lamps when dark.

polyphase machines, if the phases are in the correct relation to each other, all the lamps, will be bright or dark at the same time. If this is not the case, the leads should be interchanged until this condition is obtained.

In order to determine whether the lamps will be bright or dark for a given connection of transformers when the machines are in phase, remove the main fuses from one machine, or disconnect the machine back of the shunt connection, and throw in the main alternating-current switches with the other machine at full voltage. Since both primaries are now connected through the switches to one machine, the lamps will be in the same condition as when the main or paralleling switches are open and both machines are in phase. If the lamps burn brightly and it is desired that they be dark for an indication of synchronism, the connections of one of the primaries or one of the secondaries of the transformers should be reversed. Dark lamps as an indication of synchronism are recommended.

The lamps should be adapted for the highest voltage which they will receive, i.e., double-normal voltage. Fig. 2 shows the connections for a two-phase machine. For three-phase machines the connections are modified to correspond. For six-phase machines the phasing can be most easily done on the high-tension side for which condition one of the above connections will apply.

Feeder Wire Hanger for Mine Service

In some mines the proper method of suspending feeder wires and return cable presents quite a problem. The rib ordinarily is the logical place to put them and consequently there is on the market today any number of good hangers for supporting all sizes of wires and cables. However, even the best hanger has its drawbacks under certain conditions especially the types requiring lag screws. A hanger using two small lag screws is not always a permanent job because of the difficulty in getting a good bearing under the screws. Again, the hanger using one

large lag screw is not always good because of the difficulty of drilling one large short hole.

The accompanying figure presents a hanger which is a trifle more costly but has proved its worth by years of service. It cannot be purchased on the market but can be readily made by any blacksmith. It is made out of 1- or 1½-in. round iron, bent as shown in the figure, and flattened at one end to support the insulator. The other end is made like a wedge-bolt used so often around mines for foundation bolts, etc.

To install the hanger a hole only has to be drilled and with the use of a

Cable Support That Is Made Secure

The wedge-bolt fastened into the roof where a long hole can be drilled is greatly to be preferred to hangers that require only a shallow hole that easily breaks. Where such improved hangers are used greater spacing between supports is permissible.

sledge hammer the hanger is in place in a few minutes. The hanger is rigid and by being placed in the roof is in nearly all cases more permanent than the types that are fastened in the side walls of the gangway.

O. E. KENWORTHY.

Direction to Run Belt Splices

Spliced belts should be run in such a direction that the thin edge of the splice on the inside of the belt will be the first part of the splice to run over the pulley. See the illustration, Fig. 1.

Fig. 1—How Spliced Belt Should Run

Note that the thin edge on the inside surface of the splice runs over the pulley first.

This is the rule in most favored use; however, there is considerable difference of opinion on this matter. Frequently disagreement with the above rule is founded on the action of the air or of the pulley surface turning back the lap and thus causing the splice to break down. The splice in a rubber belt should be run in the same direction as the splice in a single leather belt.

Fig. 2—Double Leather Belt

Here the recommendations are that the thin edge of the laps on both the outside and inside surface should point away from the direction the belt travels.

Production And the Market

Bituminous-Coal Market Continues to "Mark Time" As Moribund Industrial State Persists

The feeling is quite general that unless there are false bottoms in the storage bins of the holders of big reserves, stocks are approaching the danger point in some centers, which means, of course, that a number of consumers who have been strangers to the coal market are nearly due to resume the placing of orders for fuel. In some sections, such as the New England district, where the depression in the textile industry is particularly marked, the reserve piles are still large, and consequently little activity can be expected for some time. Reports of bad business are quite general, however, the reduction in coal movement being strikingly reflected in the reports of earnings by the railroads. The formality of nominating President Coolidge and adopting a platform by the Republican convention at Cleveland last week removed another excuse for hesitancy in business, and next week will see the Democratic convention out of the way. Meanwhile the coal trade continues to mark time.

More Government Contracts Awarded

The Navy Department awarded another batch of contracts last week for supplying bituminous coal to navy yards and naval stations during the next fiscal year, beginning July 1. The awards totaled 221,150 tons, being the second lot of contracts let on the basis of proposals opened May 21. The State Department of Purchase of New York also has placed contracts for supplying the coal needs of various state institutions.

Coal Age Index of spot prices of bituminous coal reacted 4 points during the week, standing at 166 on June 16, the corresponding price being \$2.01. This compares with \$2.06 on June 9.

Activity at Hampton Roads continued its downward trend, dumpings of coal for all accounts during the week ended June 12 totaling 265,222 net tons, as com-

pared with 318,918 tons during the preceding week. Coal dumped at Lake Erie ports during the week ended June 14, according to the Ore & Coal Exchange, was as follows: Cargo, 645,978 net tons; fuel, 39,184 tons. The respective totals during the preceding week were 619,115 tons of cargo coal and 37,198 tons of fuel coal.

There was a slight rebound in the production of bituminous coal following the holiday, the output during the week ended June 7, according to the Geological

Survey, amounting to 7,378,000 net tons, which was 670,000 tons more than was produced during the week ended May 31.

Demand for anthracite continues on its well-oiled path downward since the reaction of a few weeks ago. The slackening of business is in evidence in both steam and domestic sizes. Aided and abetted by local outlaw strikes at a number of the mines of some of the large companies, there has been a corresponding shrinkage in production, which likewise has had a tendency to hold independent prices on an even keel. Ten thousand miners on strike in the Pittston district were joined last Saturday by 700 more from the Underwood colliery of the Pennsylvania Coal Co.

Estimates of Production

(In Net Tons)

BITUMINOUS

	1923	1924
May 24	11,049,000	7,163,000
May 31 (a)	10,091,000	6,708,000
June 7 (b)	10,676,000	7,378,000
Daily average	1,780,000	1,230,000
Cal. yr. to date (c)	239,358,000	204,496,000
Daily av. to date	1,773,000	1,516,000

ANTHRACITE

May 24	1,956,000	1,850,000
May 31	1,606,000	1,294,000
June 7	2,046,000	1,846,000
Cal. yr. to date	45,192,000	40,061,000

COKE

May 31 (a)	395,000	135,000
June 7 (b)	405,000	151,000
Cal. yr. to date (c)	8,799,000	5,698,000

(a) Revised from last report. (b) Subject to revision. (c) Minus one day's production to equalize number of days in the two years.

Little Change in Midwest

The Midwest market droned along during the week without enough change in any particular to have a marked effect. Some sales managers for Illinois producers thought they detected a slight improvement in storage domestic coal such as was hoped for June 1 but which did not materialize then. The domestic market is so flat that a difference of 100 cars a week from the State of Illinois is enough to be noticed. Steam coal was in no demand in spite of the small supply and the prices of last week were hard to maintain against the softening tendency. However, no price changes worthy of note were made, except 15c. off on Indiana screenings and offers of contract southern Illinois screenings at \$1.75 instead of \$1.85, which is the spot market bottom.

The smokeless market edged upward very slightly on prepared sizes, which dealers are beginning to store in small volume. Mine run continues rather soft at \$2. The June 10c. increase in anthracite is pushing a few dealers to buy at once.

Illinois fields appear to be at as low a point as they ever have touched except during a general strike. Few mines among the scattering ones that are running are getting

more than two days a week. A little railroad coal is about all that is moving. The Standard field is suffering along on practically nothing and yet screenings, which have been bringing \$1.60, have been cut down to a flat \$1.50 with not many takers.

There is nothing doing in St. Louis except a little public-school and apartment-house trade. Dealers are not storing anything either in the city or in the country towns nearby, claiming they do not know yet whether their customers are going to lean toward a cheap fuel or high-priced stuff during the coming season. Country steam demand, which had been fair, is no longer felt.

Kentucky Feels Better

Although no Kentucky coal man is cheering about anything, most of the trade feels a little better about the June outlook. A slight pick-up has been felt in industrial demand. Many buyers are beginning to see the bottoms of their respective storage piles and realize that prices can hardly get lower than they are right now. Many Hazard and Elkhorn mines are getting reasonably busy on steel, byproduct, utility and industrial orders as well as on railroad business, which is just beginning to develop. Retailers, however, are not stocking.

Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines

	1924		1923	
	June 16	June 9	June 2	June 18
Index	166	170	169	210
Weighted average price.....	\$2.01	\$2.06	\$2.04	\$2.54

This diagram shows the relative, not the actual prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913-1918," published by the Geological Survey and the War Industries Board.

The few mines of western Kentucky not affected by the strike find the going pretty hard in view of the union scale most of them are paying, but the volume produced in that end of the state is so much curtailed that the situation is easier for them. Thus far there is no indication of a break in the strike.

In eastern Kentucky the peak price appears to be around \$2.75 for best 4-in. block coal, and in western Kentucky the peak price is around \$2.50 for 6-in. block. Mine run generally is selling at around \$1.35 and up in eastern Kentucky, and from \$1.40 up in western Kentucky, the latter field getting as much for screenings as mine run. In eastern Kentucky screenings start at around 90c. and go to about \$1.25. Egg and nut sizes are in better demand in both fields of the state.

There is a gradual improvement in West Virginia, more noticeable perhaps in the southern than in the northern part of the state. Production in the high-volatile fields is larger, chiefly as a result of additional spot orders, though prices are not advancing. A considerable tonnage is moving to the lakes—not as much as usual perhaps but enough to swell production a little. Output in the Upper Potomac and adjoining regions also has taken a slight spurt.

Northwest Is More Hopeful

A steadying of prices and a slightly better movement to the docks are the only characteristics of the market at the Head-of-the-Lakes. Selling in bituminous is at a standstill, and the only revival in anthracite is a few cars that are going toward the Twin Cities since the slight reduction in rate made by the Interstate Commerce Commission.

Twenty-six boats were unloaded at the Duluth-Superior

docks last week, of which three were hard coal. Receipts for May were as follows: Anthracite, 80,240 tons; bituminous, 591,511 tons, bringing the total for the season to 164,632 for anthracite and 851,529 for bituminous. Anthracite receipts are 41,084 tons and bituminous receipts 796,099 tons less than last year.

A consensus of opinion now is that the changes which the I.C.C. has made in bituminous rates will have no effect at Duluth, as they are too slight to help the market. Anthracite, however, will be strengthened.

At Milwaukee there seems to be a hopeful feeling in coal circles, in spite of the fact that trade is very quiet at present. Conditions in the manufacturing districts must mend, however, before there can be any substantial improvement. The movement of coal by lake is slowing up, and cargo receipts totaling 157,306 tons of anthracite and 357,599 tons of soft coal are subnormal. Last year's totals up to this time were 207,619 and 706,199 tons respectively.

At the Twin Cities active buying is universally dull for the season. The unseasonable weather has had a depressing effect, and the general spirit of hesitation makes steam buyers hold off more than usual. The dock trade anticipates a better business next autumn as a result of the rate decision, and probably will stock somewhat heavier.

Production Gains Steadily in Southwest

There is no heavy activity in the Southwestern district, but a steady increase in production since mines began to reopen following the wage agreement. Production has just about kept pace with demand, so there is little or no price cutting. A little coal is being stored.

Kansas coal quotations have not changed. Arkansas semi-anthracite is \$5.50@\$6 for lump, with the possibility of an increase next month; \$3.50 for mine run, and screenings are steady at \$2. Henryetta (Okla.) lump is \$5.50; nut, \$3.75; mine run, \$3.50, and screenings, \$2.50.

Very little change was noted in the Colorado coal market during the week. Industries are buying very little and dealers absolutely refuse to place any storage orders yet. Mines worked an average of 23 hours last week and nearly 35 per cent of the working time lost was on account "no market." A slight price advance is anticipated for July 1.

In Utah trade is about dead. Industrial demand is light and dealers are refusing to store a ton, saying that their experience last summer of storing during the hot months only to see the price drop in the autumn is something they can't stand again. There is no contracting worthy of note. However prices are low and have not sunk further.

Cincinnati Market Featureless

Once again the market at Cincinnati is marking time. It is devoid of either discouraging features or the reverse. There has been a bit of a letdown in the Kentucky fields, which has kept the market from clogging to the extent that it could be in any wise called in distress. Lake buyers are still fiddling for position, holding off with a persistence that shows that this movement is in concert. However, egg and 2-in. high-volatile coals command \$1.75@\$2, which shows the determination of the operators to hold to their stand also. Smokeless jogs along at its recent gait. Orders for lump and egg have been a little slow during the week and bituminous also has slowed up. Slack is weaker because of the strength of prepared, which has caused a larger output of it.

While domestic trade at Columbus is showing a slight improvement, steam business is at a standstill. Little activity is reported in any section and both producers and distributors are playing a waiting game. One of the best features is the amount of school coal that is moving. Utilities are buying to a certain extent and railroad requirements are about normal. Contracting is quiet, as most of the larger users are content to buy on the open market to take advantage of the low prices. A few contracts have been renewed, however, but new ones are not reported.

Lake trade is rather brisk but Ohio mines, especially those in the Hocking Valley, are not sharing in the business.

The situation in the Cleveland trade is practically unchanged. The demand for steam coal is as dead as ever, and nothing has occurred as yet to lift the depression. Manufacturing plants, working part time, are still able to get along on storage fuel, picking up small lots at prices even below the already low spot level.

There is no material change in the general alignment of the Pittsburgh market. Many mines are closed entirely. Demand is coming from only a few quarters. Railroad buying continues to be light, as the roads still seem to have sizable stocks. The steel industry has been a poor buyer, but the decline in steel-mill operations is now nearly over however. There is still no general demand for Pittsburgh district coal for lake shipment. The wage reduction in the Connellsville region has not resulted in any greater steam-coal competition.

Business at Buffalo is slow, in keeping with the condition in most industrial lines.

New England Industry in the Dumps

There are those in the trade who feel that prices are at the low point of the season, but no such optimism has yet spread to possible buyers. The market hereabouts has practically reached the saturation point so far as the more active industries are concerned; the cotton mills with few exceptions are suffering such a depression that no buying is anticipated from that quarter for weeks if not months to come.

Demand inland from rehandling wharves at this end reflects the same kind of market that prevails f.o.b. Hampton Roads. All the factors are carrying heavy stocks, and since they so directly represent the several Pocahontas and New River agencies there is constant pressure to move coal enough to make room for further receipts. The nominal quotation for spot coal f.o.b. Boston is now \$5.75 per gross ton, but the local situation is by no means firmly in hand and moderate shading of this price can be looked for. At retail in Boston there is a similar situation, except that here the actual price is virtually a full dollar a ton less than the \$7.50 per net ton delivered that appears on the printed lists. Prices down to \$6.35 for deliveries through to next April have been almost general in recent weeks, especially on state and municipal business.

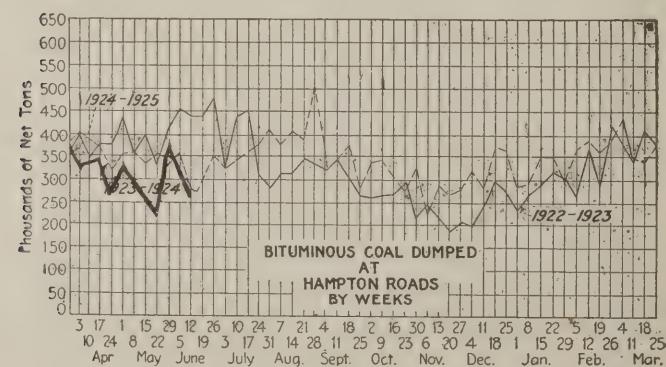

No. 1 Navy standard grades the shippers continue to hold at \$4.40 f.o.b. vessel, although occasional sales are reported at \$4.25. There are almost no comprehensive orders in the market, and a large proportion of what coal is dumped at the three piers is being applied either on coastwise contract or on blocks that were sold off-shore early in the season. No. 2 coals have sold down to \$3.95, but accumulations of this grade are not large and inquiries are relatively few:

All-rail from central Pennsylvania there is no material change. Most producers are either entirely shut down or their mines are working but one or two days a week. Via the Philadelphia and New York piers the tonnage moving is extremely light.

Demand Weak on Atlantic Seaboard

Slow demand as well as slow shipments feature the markets along the Atlantic seaboard. New York buyers continue on a hand-to-mouth diet and no inducement seems strong enough to arouse them from their indifference. Large consumers are satisfied to dig into their reserve stocks, so that about the only spot business transacted nowadays is with the small consumer, who, unfortunately for himself, cannot afford a reserve pile. Business at the New York tidewater depends largely on the position of the buyer and of the shipper. During the last week the daily average number of cars at the various docks ranged around 1,600, but the coal was kept moving and there was no actual hurry about moving it. For that reason prices were firm.

Signs of a revival are still lacking at Philadelphia. Though a turning point is looked for in July there are

some misgivings, as there are rumors that certain branches of the iron trade are likely to take an extended holiday unless orders are forthcoming soon. Industry is not at all encouraging in lines other than iron, although there are a few favorable signs, such as the reopening on a five-day schedule of plants which have been shut down for several weeks. Prices on the spot market remain firm.

Except for a few individual lines, which from time to time report healthy sales, extreme dullness is the keynote at Baltimore. Industries continue to buy for immediate use only in the majority of cases. Prices remain at the same level as for several weeks past. Stagnation has hit the export trade to a surprising extent, involving cancellation of a number of charters which had been expected to bring up the June movement to a considerable figure. Some of the local exporters now have representatives in Europe in connection with the export trade.

Birmingham reports little change in the market. Some interests note a better inquiry and some actual new business taken on, while others are unable to discern any upward trend. It is the consensus of opinion that the lull is due entirely to the industrial slump and that any stimulus in this direction will be promptly reflected in a more active market and increased requirements, as there are no stocks in the hands of consumers.

Anthracite Demand Continues to Slacken

Lack of demand is keeping pace with the cut in production due to labor troubles and holidays at the mines. The situation is slowly but gradually growing easier. Dealers have full yards and consumers are showing no desire to empty them. While it has been an active spring for retail dealers, due in most part to unseasonable weather conditions, buyers do not show any desire to avail themselves of the present prices, although wholesale as well as retail prices are subject to at least a 10c. per ton advance on the first of each month until September. Retail dealers are not anxious for independent coal since they can get sufficient company product to take care of their needs. While the maximum current quotation for independent domestic coals is about \$9.25, straight stove coal brings as high as \$9.75, the lower figure covering mixed orders of egg, stove and chestnut. Pea coal moves quietly and there is comparatively little strength in the buckwheat sizes.

The Philadelphia market continues to soften; were it not for the pressure exerted for stove, and to a lesser degree on egg, there would be nothing of moment in the market whatever. Pea is showing signs of heaviness, as the larger companies are compelled to store it. The steam market is particularly poor, a large surplus going to storage yards.

Baltimore dealers have decided to stick to their original schedule not to raise prices before July 1. Considerable discussion has been raised over an average jump in wholesale prices of between 30 and 35c. per ton. It had originally been planned, on the theory that wholesale prices would increase about 10c. per month from May to September, to absorb this 50c. boost by two advances at retail, one on July 1 of 25c. and one on Sept. 1 of 25c., but dealers may be forced to take an entirely different course.

Foreign Market And Export News

Recovery of British Coal Market Slow; Output Declines Again

Though business in the South Wales market has expanded somewhat, complete recovery of the industry has been impeded by the uncertain labor outlook. There is a fair amount of inquiry but business is very slow. The holdings also have been instrumental in curtailing the volume of orders. Foreign buyers are apprehensive, which no doubt accounts for some of the business going away which normally comes to Britain. Italian and South American purchases are poor, and French and other European inquiries are fitful.

The Newcastle market is weak and dull, though the tone on forward business is better. Some German and Dutch consumers are taking small quantities, but their orders are inconsiderable. The supply is much in excess of the demand and many of the collieries are producing only as much coal as they are likely to sell immediately.

The agreement for the regulation of wages in the British coal-mining industry has been ratified by the miners by a majority of 162,000 in a total vote of 784,000. The agreement is now in force for a period of 12 months; after that it is subject to annulment on one month's notice on either side.

A special cable to *Coal Age* states that British collieries during the week ended May 31 produced 5,308,000 tons, according to the official reports. This compares with 5,436,000 tons during the week ended May 24.

Market Sags at Hampton Roads; Bunkers Alone Hold Up

Business at Hampton Roads is dull, with the market slightly weaker, and with bunker business alone holding its own. Considerable movement to South America on old contracts, which is having no immediate effect on the trade, is one of the features of the situation.

Coastwise business is fair and foreign movement is dropping to a marked degree. Dumpings for the week fell

away still further, and a low record for monthly movement is forecast by shippers. The supply of coal at tide shows some improvement, but it is due to lack of demand more than to any greater movement from the mines. The tone of the market is dull and no immediate improvement is in prospect.

French Market Firmer, Aided by Exchange and Ruhr Turmoil

Due to the pressure of exchange and the labor situation in the Ruhr the position of the French coal market has improved. The demand for industrial coals is better, on account of the curtailment of arrivals from Germany. The situation in house coals, however, is dull, in spite of the attraction of summer rates. The supply of rolling stocks has been satisfactory with the freight rate lower at 21 fr., Bethune-Paris.

Receipts of indemnity fuels by France and Luxemburg between May 1 and 17 were 156,750 tons of coal, 248,000 tons of coke and 15,770 tons of lignite briquets, or a total of 420,600 tons. During the first four months of 1924 the Ruhr sent to France (coke reduced to its equivalent of crude coal on the basis of 3 tons of coke for 4 tons coal) 787,031 tons in January, 888,965 tons in February, 1,028,446 tons in March and 1,371,000 tons in April. The program of the Reparation Commission called for 735,000 tons per month during the first quarter, but the quota for April was only 684,000 tons. The tonnages imposed by the Reparation Commission are getting lower in proportion as the output increases in the French devastated mines.

Fuel imports for April consisted of 2,228,024 tons of coal, 703,446 tons of coke and 54,205 tons of patent fuel. The figures for March were 2,185,954 tons of coal, 491,625 tons of coke and 96,391 tons of patent fuel.

French exports of fuel during April comprised 178,781 tons of coal, 49,711 tons of coke and 8,517 tons of patent fuel, as compared with the following for March: 178,327 tons of coal, 49,412 tons of coke and 18,104 tons of patent fuel.

News Items From Field and Trade

COLORADO

An electric power plant is soon to be erected at the Pike View mine of the Pike's Peak Consolidated Fuel Co., Colorado Springs, to supply power for the mine and for the Golden Cycle ore-reduction mill in that city, owned by related capital. The mill is now served by the Colorado Springs city electric light plant, which last year sold the mill about 8,000,000 kw.-hr. of current for about \$70,000, which is said to be less than the cost of producing the power. The city company sold the remaining 11,000,000 kw.-hr. of its output to its customers for \$479,000.

IDAHO

Negotiations are still in progress concerning the Teton Coal Co.'s plan to mine coal in the Teton basin. After a long series of hearings and various investigations for the State Public Utilities Commission, a decision is now awaited which may order the Oregon Short Line to operate the 11 miles of abandoned track from Teton Junction to the mine sites. The road asserts that the prospective coal traffic out of the mines will not justify the cost of repairing the spur, but H. F. Samuels, politician and president of the coal company, has worked up a great deal of public sentiment in favor of his move to force the road to give his prospective mines service. The road proposed that he put up the money for the repairs. His counter proposal is that he will guarantee to ship 29,920 tons of coal annually and furnish a bond of \$36,910—the estimated cost of opening the line—if the railroad will guarantee certain low freight rates on his coal to certain towns within 125 miles. The case hangs fire.

ILLINOIS

The Illinois Coal Corporation, Chicago, has completed a 200-ft. concrete smokestack at its twin mine at Nason, in Jefferson County and has erected a tippie at one of the shafts. The tippie at the other is expected to be completed early in the autumn.

George A. Harwood, who has been promoted by the New York Central Lines, has resigned the vice-presidency of the Chicago & Harrisburg Coal Co. He has been succeeded by Walter R. Gibbons, real estate and tax agent of the Big Four road, of which the Chicago & Harrisburg Coal Co. is a subsidiary.

What is said to be the largest strip

coal mine in Illinois was recently opened by the United Electric Co. near Lewistown. The mine is on a 2,000 acre tract and equipment has been installed capable of producing 80 carloads of coal per day. The coal is reached 20 to 40 ft. below the surface; powerful shovels take off the top covering of earth while smaller shovels follow up and extract the coal. It is estimated it will require 30 years to remove all of the coal on the land.

INDIANA

Judgment for \$21,236.89 returned Nov. 2, 1923, in the circuit court at Lebanon, in favor of the Black Comet Coal Mining Co. against the Indianapolis Street Railway Co. will stand, it is believed by Indianapolis attorneys, because the proposed appeal to the state Supreme Court was lost for failure to file the necessary papers within the 180 days required by the court rules. It is thought the defendant will be compelled to pay the judgment with interest and costs, amounting to \$22,021.19. The case involved the purchase and delivery of 6,043.2 tons of coal and the judgment is one of the largest returned in the circuit courts of central Indiana for many years.

KENTUCKY

J. T. Dougherty, formerly president of the Jellico Coal & Coke Co., recently became secretary-treasurer of the Harlan Jellico Coal Co., of Louisville.

It was reported from Whitesburg on June 8 that the Ulvah Coal Co., at Bluefield, Lechter County, after being idle for several months, was preparing to resume operations. The company is controlled by West Virginia interests.

The Island Creek Coal Co. has declared an extra dividend of \$1 on the common and the regular quarterly dividends of \$2 on the common and \$1.50 on the preferred stocks, payable July to stock of record June 20.

The men who went on strike at Straight Creek, where several men were recently killed by shooting up the camp, and were ejected from the property of the Liberty Coal & Coke Co. by Judge Cochran, of the U. S. District Court, under injunction proceedings, have all moved to Molus, in Harlan County, the property of the Wallins Creek Collieries Co., of which Mike Roach, of Charleston, W. Va., is president. About 50 families were affected by the injunction proceedings against members of the United Mine Workers. The Molus-Roach plant has been closed

down for some time and will not be able at present to offer work to these men.

The mines of the Jamieson Coal Co., near Idamay, on Sturgeon Creek, above Beattyville, were flooded, company bridges washed out, and two miles of the branch line of the Louisville & Nashville R.R., inundated as a result of a cloudburst in the upper sections of Sturgeon Creek. The damage is estimated at \$300,000 or more, the plant of the Petroleum Carbon Black Co., a West Virginia corporation, having been washed out. Families of miners had to be carried to safety before the crest was reached. For a while wires were down and the town cut off from communication. So far as known no one was injured, and all miners got out of the mines before the plant was flooded.

MARYLAND

Olin D. Robinson has filed a petition in the Circuit Court of Allegany County, praying that the Midland Georges Creek Big Vein Coal Co. be dissolved and a receiver appointed to assume charge of the affairs of the corporation. Robinson asserts that he is a stockholder in the corporation, that it is indebted to him, that the corporation is insolvent and has no money to meet its obligations. The company was organized in 1920, leasing a small tract near Midland, owned by the Consolidation Coal Co. Among other stockholders in the company are Joseph E. Ravenscroft, of McCoole, and Clarence Fletcher, of Frostburg.

MINNESOTA

The Peabody Coal Co., Chicago, has opened an office in Minneapolis, at 614 Plymouth Building, with E. E. Heiner as district sales manager. He formerly was with the Superior Coal & Dock Co.

The summer schedule of a 10c. a month advance on hard coal added that amount on June 1, as has generally been the case each month through the summer. It is a regular custom, but for some reason it caused a little daily press spasm this time.

MISSOURI

Drillers are at work on the King farm, east of Liberty, sinking a test hole for coal and are down about 100 ft. now. It is expected that coal will be found at a depth of about 240 feet.

The St. Louis Southwestern Ry. will open bids at noon June 25 at Room 908, Pontiac Building, St. Louis, on from 300,000 to 500,000 net tons of bitu-

minous mine-run coal suitable for locomotive use, to be used as needed. Quotations are to be submitted f.o.b. cars at sellers' mines.

The Coal By-Products Engineering Co. has purchased a 10-acre tract at the intersection of the Tesson Ferry road with the Missouri Pacific R.R. and is erecting a 100-ton smokeless fuel and coal byproduct plant. The plant will produce coal for domestic purposes through a process invented by George Johns, utilizing bituminous and mine fines, lignites and other low-grade fuel. The byproducts recovered, such as gas, oils, tars, creosote, ammonia and sulphate of ammonia, will be sold to the domestic market.

The Mosby Block Coal Co., recently incorporated for \$100,000, has obtained a lease on the Mosby Coal Co., for a period of fifty years for the purpose of mining and selling coal. The coal company under the terms of the contract is to receive 20 per cent of the profits and the Mosby Block Coal Co., the lessee, is to receive 80 per cent of the profits. The last-named company is to make certain permanent improvements for which it will be reimbursed at the termination of the lease with a deduction of 2 per cent per year.

NEW YORK

Marcus L. Bell, vice-president of the Chicago, Rock Island & Pacific R.R., and Frank Burns, president of Burns Brothers, were elected directors of the Coal & Iron National Bank at a meeting of the board held June 11. Mr. Burns succeeds his father, M. F. Burns, deceased.

OHIO

The Southern Ohio Coal Exchange reporting for the week ending May 31 shows a total production of but 58,786 tons out of a full-time capacity of 540,152 tons from 440 mines reporting.

This leaves a shortage of 481,366 tons. Labor shortage was responsible for a loss of 4,740 tons; strikes, 6,280 tons; mine disability, 855 tons and "no market" 459,491. This was a five-day week because of the intervention of Decoration Day. During the same week the eastern Ohio field ordered 8,442 cars and loaded 6,153 cars.

H. S. Brown, who has been manager of the Columbus office of the Philadelphia & Cleveland Coal Co., has been placed in charge of the Indianapolis office, and R. J. Bush, formerly connected with the Cincinnati office, has been named manager to fill the vacancy.

The Morrow-Callahan Coal Co. offices in the Dixie Terminal Building, Cincinnati, have closed. J. D. A. Morrow, who was in charge, will hereafter devote all his attention to his duties as vice-president and general manager of the Joy Machine Co., Pittsburgh, Pa.

The strike of the Cannan Coal Co., Cannanville, is still on and there is a loss of approximately 6,500 tons per week owing to the layoff. Efforts on the part of operators to end the strike have proved futile. The difficulty is over the question of payment for dead work.

The Citizens Trust & Saving Bank, of Columbus, has brought a suit in federal court seeking to establish its claims as a prior lien on properties of the Maynard Coal Co., now in the hands of W. S. Harmon and Frank L. Stein, receivers. The petitioning bank is a trustee under a mortgage deed for a \$1,500,000 bond issue, of which \$680,000 is outstanding. This is secured by a mortgage on the coal properties and 5,500 shares of stock of the Superior Coal & Dock Co., a subsidiary.

Governor Donahey has written a letter to John E. Harper, Director of Public Welfare, which department has charge of the operation of 23 state institutions, urging him to lay in the winter's supply of fuel now in order to help the mining situation in the Hock-

ing Valley. The annual consumption of coal at the various state institutions is about 150,000 tons, mostly mine run and screenings. It is believed that by purchasing now funds available after July 1 can be used to pay for the coal.

The Rice Coal Co., of Dayton, announces the appointment of Earl Wertz as northern sales agent, with headquarters at 839 Ohio Bldg., Toledo. Mr. Wertz will have charge of the distribution of the output of the company's mines in addition to which has been added the output of the Keel Coal Co. at Pauley, Ky., and the Columbia Coal Co.

PENNSYLVANIA

Thin-vein mining is more in evidence in the Hazleton region. The big measures have been worked for from fifty to seventy-five years, and it has been found advisable to take the coal out of the smaller strata.

The Lehigh & Wilkes-Barre Coal Co. has declared a dividend at the rate of 7 per cent a year on the preferred stock or 1½ per cent for the period from April 1 to June 1, and a dividend of \$3 a share on the common stock, payable June 2 to stock of record May 20.

The mines of the Cascade Coal & Coke Co., at Sykesville, controlled by Rogers, Brown & Co., have been closed because the union miners refused to work at reduced wages. It is expected that the company's mines at Tyler, in the same vicinity, will close soon for the same reason.

The oft-repeated statement that the coal supply of the country will give out within a hundred years has been sharply challenged by the engineers of the Lehigh Coal & Navigation Co., who are preparing plans for extensive stripping operations in the Panther Creek Valley near Lansford.

Work has been started on the removal of coal from the new stripping of the Wolf Coal Co. on the Beisel tract, between Drifton and Lattimer. Coal measures were exposed a week ago. The coal is being prepared at the Drifton breaker. The tonnage is shipped over the Lehigh Valley railroad.

Mayor E. J. Healey, of Carbondale, last week ordered Anthony Pinaro, a contractor, to cease operations in three veins surrounding a mine fire in that city. The contractor was removing the coal from the surface and was filling in with dirt in an effort to check the mine fire. Residents of the vicinity complained to the Mayor that the operation was a menace to their health and property. The situation is being investigated by the City Council and mining engineers.

The Lehigh Valley Coal Co., recently segregated from the Lehigh Valley R.R., reports net income of \$6,449,516 for 1923. After allowing for all interest charges, including interest on the new 5 per cent bonds, and allowing for federal tax reserves, the company reports a balance of \$4,495,064, or \$3.70 a share on the 1,212,000 shares of capital stock sold to stockholders of the Lehigh Valley R.R. No dividend has been declared by the coal company

Courtesy U. S. Distributing Corp.

Tipple of Sheridan-Wyoming Coal Co., Carney, Wyo.

This property formerly belonged to the Carney Coal Co. and is one of the leading mines in the north of the state.

since its segregation from the railroad property, but it is reported that a dividend of at least \$2 a share annually is expected on the stock before the end of this year.

The Pennsylvania Coal Co. made the following changes at three of the company's largest collieries June 1, according to an announcement by J. P. Jennings, general superintendent of the Pittston district; Superintendent James C. Johnson, transferred from the Butler colliery, Pittston, to the Central colliery, Avoca; Superintendent T. H. O'Brien, of Avoca, from the Central colliery to No. 9 colliery, Pittston, and Superintendent Thomas Huntley, of Pittston, from No. 9 colliery to the Butler colliery, at Pittston.

A controversy at Mine No. 5 of the Portage Coal Mining Co., at Portage, Cambria County, which resulted in a strike on Feb. 2, involving 450 men, has been settled, the men agreeing to return to work on the terms proposed by the company at the time the strike was called. The strike was against the wishes of the United Mine Workers officials. The vein mined in this operation contains about 1 ft. of inferior coal, known as "rooster" coal. This the company ordered not shot down and the miners went on a strike, alleging that the order reduced their earning capacity.

Fatal mine accidents showed a 16 per cent falling off in the first five months of this year, according to Secretary of Mines Joseph J. Walsh. Whereas 410 miners lost their lives in mine accidents in Pennsylvania during the first five months of 1923, the number of fatalities in the similar period in 1924 totals 343, a decrease of 67 deaths. "In the anthracite region," Secretary Walsh stated, "there were 237 fatal accidents in the first five months of 1923, as compared with 198 in the same period of 1924. "In the bituminous region there were 173 fatal accidents as compared with 145 in the same five months of 1924."

WASHINGTON

The Black Carbon Coal Co. is approaching the operating point with its property near Buckley, which is aimed to be a 300-ton mine. The company has bought the properties once operated as the Spiketown, Morristown and Pittsburgh mines. The officers of the company are Fraser H. Lantz, general manager; James Kelley, assistant general manager; David Grey, superintendent and engineer; James C. McCracken, secretary-treasurer and in charge of the Seattle office.

WEST VIRGINIA

There is more activity in the New River field now that the Loop Creek mines are running on a full-time basis, including the McKell Coal & Coke Co. mines and the Sun and Price Hill mines.

The Huntington Coal Sales Co., of Huntington, has filed articles of dissolution in the office of the Secretary of State and will discontinue its corporate existence. The New Pocahontas Coal

Co., of Huntington, also has filed a certificate of dissolution.

In connection with the suit of the Shrewsbury Coal Company for \$75,000 damage for alleged failure to take coal under contract, brought against the Hooper-Mankin Fuel Co., of Huntington, the Circuit Court of Kanawha County after presentation of evidence in the case, directed a verdict in favor of the defendant.

A deed recorded in the office of the County Clerk of Monongalia County shows the sale by the W. A. Stone Fuel Co. of about 342 acres of land with underlying coal in Union district of Monongalia County. The estimated consideration was \$50,000. The Morris, Stewart and Colebank tracts are involved. The coal is in the Pittsburgh seam.

The Benwood explosion on April 28, in which 119 miners were killed, made the list of casualties in West Virginia mines during April unusually large, 141 men having perished in the mines of the state during that month. One hundred and nineteen deaths occurred in Marshall County, five in Raleigh County, 3 in Fayette County, 4 in Logan County, 2 in Greenbrier County, and one each in Clay, Kanawha, Marion, McDowell, Mercer, Ohio, Preston and Tucker County. Aside from the large toll in the Benwood disaster there were 22 fatalities, 16 of which resulted from a fall of slate, other deaths being due to miscellaneous causes.

WISCONSIN

Affairs of the defunct Valley Coal & Dock Co., of Milwaukee, are being investigated by a federal grand jury. It is charged that a Milwaukee man interested in the company obtained large credit for the concern on false representations.

CANADA

The Clear Mountain Coal Co., which is said to be investing \$300,000 in developing Lillooet sub-bituminous coal near Ashcroft, B. C., is now putting that coal on the Vancouver market, hauling it by rail from upper Hat Creek to Squamish and by water to Vancouver.

The Pacific Coast Coal Mines, which formerly operated the Morden mine, near South Wellington, B. C., which has been in liquidation, is being re-organized and is expected to resume operations next autumn. The company also owns a coal concession at Hequash, near Alert Bay, where some development work has been done.

In the first-aid competitions both for the British Columbia championship (Senior) and the Wallace Nesbitt Cup (Junior), held under the auspices of the St. Johns Ambulance Association, the Nanaimo "A" team (Western Fuel Corporation of Canada) scored the highest number of points among the seniors, with 268 out of a possible 325, the juniors of the same corporation obtaining first place in their class with 185½ points. The latter were given a close run by the Fernie 4th Troop of

Boy Scouts with 175 out of a possible 250.

Striking miners in the Drumheller district of Alberta received their first relief from the international organization at Indianapolis on June 6. It was distributed in the form of orders for groceries and clothing, single men receiving \$2 per week and married men \$4 a week with 50c. additional for each child. The stand taken by President John L. Lewis and the International officers is that relief will be given only when cases are considered needy.

The Pacific Coast Coal Mines, Ltd., at one time one of the big producing coal operators of Vancouver Island, is to resume work within a few months. The company acquired a large acreage near South Wellington which was developed during 1909, 1910, 1911 and 1912 until it was mining about 215,000 tons a year. In 1911 New York interests gained control but litigation finally led to the sale of the property by the Sheriff of Nanaimo in 1922. The property then was bought in by some of those most largely interested financially. Since that time the mine has been idle. It may be said, as to the present holdings, that the Morden Mine, which is located on the 1,500 acre block, South Wellington, possesses the most modern colliery plant on the Pacific Coast. This mine is connected to the shipping point at Boat Harbor, east coast of Vancouver Island, about five and a half miles from the mine, with a standard-gauge railroad and is provided with all necessary rolling stock. At tidewater there are shipping wharves, bunkers, washeries and loading conveyors.

Association Activities

A general meeting of the **Smokeless Coal Operators' Association** has been called by the president, Robert H. Gross, to be held Thursday morning, July 12, at the Hotel Washington, Washington, D. C.

The "Shop Talk" meeting of the **Fayette-Greene Coal Producers' Association**, on Wednesday evening, June 11, at the Summit Hotel, near Uniontown, Pa., brought out about 100 coal and coke company officers, superintendents, master mechanics and mine foremen. After an enjoyable repast, G. Carl Areford, President of the association, introduced William Z. Price, assistant general superintendent of the Buckeye Coal Co., of Nemacolin, Greene Co., who presided. The principal topic of the evening was rock dusting, and the first speaker of the evening, Captain Edward Steidle, of Pittsburgh, Pa., in charge of the short mining course at the Carnegie Institute of Technology, read a very comprehensive paper on the subject. He was followed by A. C. Fieldner, superintendent of the U. S. Bureau of Mines station at Pittsburgh, who also spoke on the same subject. State Mine Inspectors Edward E. Girod, of Masontown, and Richard Maize, of Uniontown, also took part in the short discussion. Edward H. Cox, general manager of the Snowdon Coke Co., of Brownsville, gave a talk on machine loading, and was followed by Frank W. Newhall, of Uniontown, chief engineer of the Republic Iron & Steel Co.'s coal and coke plants, who made a few remarks on the same subject. Clyde Elkins, of Connellsville, inspector for the State Compensation Insurance Fund, read a paper on mine safety. M. D. Cooper, of Pittsburgh, assistant general superintendent of the Hillman Coal & Coke Co. and president of the Coal Mining Institute of America, spoke briefly on the topics of the evening and called attention to the next annual session of the Institute to be held next December, at which rock dusting is to be one of the chief topics of discussion.

Traffic News

Commerce Commission Approves Clinchfield Lease

The Interstate Commerce Commission on June 12 approved the applications of the Atlantic Coast Line and the Louisville & Nashville R.R. for joint control of the Clinchfield Ry. system. The commission approved the lease under certain conditions, which were submitted to those interested in the Clinchfield properties on Feb. 9 last, but protested against by the applicants. Opposition to the granting of the application also was voiced by the Seaboard Air Line and other carriers.

The commission also granted the applicants authority to assume, as lessees, obligation of paying as rental for the property rights and franchises of the Carolina, Clinchfield & Ohio Ry. and its subsidiaries amounts equivalent to dividends at certain rates upon \$25,000,000 of common capital stock and interest upon certain bonds and equipment obligations of the Clinchfield in the amount of \$28,292,000 now outstanding and, the commission said, as guaranteed by the lessor of the property upon \$1,500,000 of Holston Corporation 5 per cent realty and collateral trust convertible notes.

Indiana Rate Cut Deferred

The recent order of the Indiana Public Service Commission reducing intrastate coal freight rates will not become effective until July 1, an agreement having been reached between attorneys of the commission and attorneys for 21 railroads that brought suit in the Superior Court before Judge Linn D. Hay, to have the order of the commission set aside. The order was originally intended to go into effect April 1, but the date was postponed from time to time until after the hearing. Judge Hay said that the case will not be decided before the latter part of June.

Obituary

Joseph Shelly Sillyman died last week in Philadelphia, of a complication of diseases. He was born at Pottsville, Pa., on May 5, 1847. After graduation from the academy in that city he followed the profession of civil and mining engineer in Pottsville and Hazleton, Pa., being one of the best known engineers in central Pennsylvania, widely recognized as an expert in mineral lands and mining. The practice of his profession took him into nearly all parts of the bituminous-coal fields in Pennsylvania, West Virginia and eastern Kentucky.

Donald McDonald, Sr., vice-president and general manager of the Louisville Gas & Electric Co., a Byllesby subsidiary, died suddenly June 3 following a stroke of apoplexy at the completion of a talk June 3, before the Electric Club, Louisville. He had just made a strong

address in favor of passage of a \$75,000,000 bond issue for roads and schools in the fall elections, under an enabling act passed by the recent Legislature. The Louisville Gas & Electric Co. owns its own coal mines at Echols, in Western Kentucky and has a fleet of battleship hopper cars, used for transporting its fuel to Louisville during periods of car shortage.

Will O. Davis, 62 years of age, secretary-treasurer of the Kentucky River Coal Co., Lexington, Ky., and prominent lawyer, died at his home at Versailles, Ky., a few days ago of apoplexy, having become ill while in Louisville two weeks prior to his death. He had recently been named state manager for Oscar W. Underwood, Democratic candidate for President, who was his old classmate at college.

David C. Thomas, of Columbus, Ohio, a retired coal operator, was instantly killed recently by falling from the 15th floor of the building at 8 E. Broad St. in that city. He was for many years head of the D. C. Thomas Coal Co., with main offices in Columbus. He sold out in 1919 to the Hisylvania Coal Co. and retired from active business, although nominally vice-president of the Piney Fork Coal Co. and the Panhandle Collieries Co., for which the Hisylvania is selling agent. He is survived by his wife, a son and five daughters.

Publications Received

Analyses of Ohio Coals. Bureau of Mines, Washington, D. C. Technical paper 344. Pp. 39; 6x9 in.; tables.

An Investigation of the Maximum Temperatures and Pressures Attainable in the Combustion of Gaseous and Liquid Fuels, by G. A. Goodenough and G. T. Felbeck. Engineering Experiment Station, University of Illinois, Urbana, Ill. Bulletin 139. Pp. 160; 6x9 in.; illustrated.

First General Report of the Lignite Utilization Board of Canada, Montreal, Canada. Pp. 263; 6x9 in.; illustrated. This complete and well illustrated report covers operations from Oct. 1, 1918, to Jan. 1, 1924.

Report on the Mines of Province of Nova Scotia for 1923. Department of Public Works and Mines, Halifax, N. S. Pp. 215; 6x9 in.; tables.

Mechanical Engineers' Handbook. New second edition, by Lionel S. Marks. Pp. 2,000; 4½x7 in.; illustrated. Price \$6. All material in this book has been brought up to date and much new matter included. McGraw-Hill Book Co., Inc., 370 Seventh Ave., New York City.

Coming Meetings

American Society for Testing Materials; annual meeting, Chalfonte Hotel, Atlantic City, N. J., June 23-27. Secretary, Edgar Marburg, University of Pennsylvania, Philadelphia, Pa.

American Institute of Electrical Engineers, annual convention, June 23-27, Edgewater Beach, Chicago, Ill. Secretary, F. L. Hutchinson, 29 West 39th St., New York City.

First International Management Congress, Prague, Czechoslovakia, July 21-24.

World Power Conference, Wembley, London, England, June 30-July 12. O. C. Merrill, Federal Power Commission, Washington, D. C.

Rocky Mountain Coal Mining Institute. Summer meeting, Aug. 7-9, Rock Springs, Wyo. Secretary, Benedict Shubart, 521 Boston Bldg., Denver, Colo.

New Equipment

Temperature Indicator for Transformers

W. D. Crumpton & Co., 8 Bridge Street, New York, sole distributors for the Packard Electric Company, Ltd., St. Catharines, Ontario, Can., recently

placed on the market the Baker transformer temperature signal. This device is operated by a thermostat which moves a rod to which is mounted a drum, thus indicating the temperature of the transformer at all times. Part of the device consists of a maximum high temperature indicator which records at all times the highest temperature obtained by the transformer oil. The maximum high temperature drum is colored red and white. Red denoting overload, white denoting safe load. A white and black disc indicates underload. Temperature indications are shown against large figures which can be readily observed from the street

Instrument Tells Amount of Load

The safe loading of a transformer is a function of the temperature. This device records the temperature of the oil and thus gives a visual indication of the load.

level through a glass window in the head of the instrument. The materials used in the construction of this device are non-corrosive metals, all parts are sealed so as not to leak water or any vapor. The standard size stems are 7 in., 9 in. and 12 in., but any other length can be made to order.

Switch Timed by Synchronous Motor

For the control of circuits of moderate rating, a new automatic time switch, has been developed by the General Electric Co. The principal feature of the new device is the adoption of a Warren synchronous motor in place of the conventional spring-driven clock commonly employed to operate the timing mechanism. The new switch is for use on alternating-current circuits.

The function of this device is the same as that of the many other forms of time switches now on the market. It differs markedly from these other types, however, in that its time-keeping and propelling member is in the form of a small synchronous motor instead of the usual clock with escapement mechanism and spring. Control is effected by automatically closing and

Automatic Time Switch

The timing mechanism of this device is driven by a synchronous motor, thus the usual clock attachment is not necessary and no winding is required. Operations which must start and stop at definite periods can now be accomplished with regularity.

later opening the circuit at any predetermined time for which the switch may be set. It is especially adapted for use with electrically driven pumps, compressors, motor-generator sets, battery charging apparatus, lighting systems, etc.

The new switch, is about 12 in. high, 5 in. wide and about 4 in. deep. It is enclosed in a weatherproof case, thus being adapted for outdoor mounting as well as for mine service. It is rated 20 amperes, double-pole, single-throw, for use on circuits not exceeding 250 volts.

Mine Car Is Equipped with One-Piece Drop Bottom

One of the points where cars are frequently delayed longer than necessary is at the tipple dump. Naturally

if cars must be uncoupled, discharged one at a time and then coupled together again the entire process consumes much time and also requires the services of several men. If cars can be dumped consecutively without being detached from each other, simply by being drawn along by some mechanical means, not only would the time of dumping be reduced but the operation would be simplified and the cost lowered.

To attain this end P. W. Holstein has invented and placed on the market the drop-bottom car shown in the accompanying illustration. As may be seen the drawbar extends through and is attached to the car box only. The wooden bottom, to which the running gears are, of course, fastened, is securely hinged to the car box at the forward end. Angle-iron guides along the sides of the bottom assure that the two parts will return to proper position after they have swung apart in dumping. Along the top of the car box also is a wide angle-iron stiffener or gunwale.

The dump upon which this car discharges is likewise of simple type. It consists merely of a suitable depression in the track over a pit or bin for receiving the coal and a pair of chains upon either side. These chains engage the gunwales of the cars and support the car box as it moves across the dump. The bottom of the car on the other hand is supported by the car box at the hinged end and by the rear wheels at the other. As the rear wheels therefore take the depression in the track the bottom of the car swings open discharging the contents but returns to normal position as the rails again rise to their proper level relative to the chains.

Any number of cars may be discharged by this dump without stopping or uncoupling from each other. A dump of this variety has been in operation at a Kentucky mine for over two years

and has given entire satisfaction. The cars employed at this operation, however, are of a slightly different model, lacking the through drawbar and being fitted with lugs instead of the gunwale. The differences, however, are not so pronounced as to cause any particular variation in their operation.

Flow Meter With New Integrating Unit

The Cochrane Corporation of Philadelphia has recently added an integrating device to its new type flow meter used for measuring water and steam in pipe lines. It is claimed that this additional device imposes no load or resistance to the operation of the meter and as a consequence the sensitivity and accuracy of the meter is not impaired.

The integrator is driven by a clock, the deflecting member of the meter merely controlling the position of a stop or motion-limiting pin. Its operation is similar in principle to the method used by steam engineers for obtaining the mean effective pressure from an engine indicator card, which consists in ruling evenly spaced parallel lines across the chart, adding up the lengths of the lines intercepted between the indicator lines and then dividing by the total number of lines which have been added. The indicator goes through motions equivalent to drawing a line from zero to the pen trace on the flow-meter chart once each minute, the length of this line being proportional to the momentary rate of flow and the sum of the lines proportional to the total flow for a definite period. The integrator can easily be calibrated and is said to give results within 1 per cent of absolute accuracy in a run during which the flow varies between 20 per cent and 100 per cent of full-load rating.

Details of New Drop-Bottom Car and Elevation of Its Dump

The bottom of this car is hinged to the body at one end. On the dump the car body is supported by two chains, one upon either side, while the rear wheels follow the rails. The bottom thus swings open and then closes again in the manner shown.

Number 26

Our Case Like the Farmer's

CROP shortages and Government assistance have demoralized the farmers, as coal shortages, strikes and railroad inabilities with consequent high prices have demoralized the coal industry. It is difficult to tell how many years it will take to put either of the industries properly on their feet, so much have they suffered from over-expansion and the consequent excessive competition. If the coal men could combine in times of high prices to keep the price of coal down and to see that the ultimate consumer gets the benefit of that fact there would be less speculation, less consumer ownership of coal properties, an important cause of over development, and the industry would be on a surer footing.

Example of the Powder Companies

OPERATORS have convinced themselves quite generally that their business is done when they have produced the coal. It is the consumer's business, they say, to learn how to burn it. Of course, there are exceptions. After all there are different kinds of coal, and if one has only one kind to sell it pays to help the buyer to get good results. It helps to hold trade. If one has many kinds it is profitable to see that the consumer gets the kind that suits him and that gives him best value; it is well to see that he burns it economically. That promotes satisfaction and holds a customer.

But when a rival like oil is met, the coal men can get together to promote the common end. The menace is best overborne by making the consumer thrive so well burning coal that he will want no other fuel. The Kansas coal men are striving to achieve some such co-operation and some of the coal men elsewhere are endeavoring to create what they are pleased after the popular manner to term an institute. Whatever it is named it will have the same end in view.

Powder companies are setting the coal men a good example. They, individually, are trying to enable the operator to get lump coal with minimum risk to life, limb and property. Their function is to sell powder, but they believe it is also their duty to help the consumer to use it effectively. They even try to make him use less of it. They advocate open spaces in shot-holes and rock dust instead of heavy, tight shots. Not by any means wholly unused to selling service the operators of coal mines can nevertheless learn a lesson from the powder manufacturer. In fact it is the genius of the hour to sell service and not merely a product.

Mr. Lewis, Keep Your Seat

NOBODY seems to be training to run against John Lewis next December for the presidency of the United Mine Workers. We hope nobody will. Mr.

Lewis is a good man for the job and he ought to stick to it, for if ever in history the union miners of this country needed a strong, sound leader, it is now. It is going to take a mighty good man to hold the organization together when it becomes necessary for that organization to take the backward step in wages as it has done in West Kentucky. Lewis will come as near to holding it together as anybody and operators in the strong union fields ought to be glad of that. It is distinctly to their interest that the United Mine Workers remain a representative unit with which to deal. There would be chaos indeed in the coal industry were there no such unit. Let us hope the union will not break, for the system of checks and balances which exists between unionism and non-unionism in coal is a healthy though oftentimes painful thing for the industry.

In a way it is unfortunate that President Lewis, facing the future that he faced before Jacksonville, waved his lion's mane so belligerently when he said he would never take a backward step in the matter of wages. Fortunately, however, a good politician can say a great many pompous and important things before election which are easily forgotten afterward. Mr. Lewis may have this comforting truth yet to learn. In past years he has not been a suave, wily politician. He has been a bludgeon swinger and a good one. His has been a victor's march. He has strewn his course with ultimatums delivered in the well known "loud stentorian tone." It remains to be proven that he is diplomat enough to accept for his men a wage that the coal industry can afford to pay. But he is a good man and we have hopes.

Shall Gas Be Made At the Mines?

THOUGH such a redoubtable authority as G. S. Brewer, the assistant fuel engineer of the U. S. Bureau of Mines, answers "No," to the question "Should Buffalo's gas be made at the coal mines?" the industry cannot but feel that the suggestion has not been and will not be definitely and finally shelved, especially where market and mine are closer to each other than is the case at Buffalo. It seems such a reasonable proposition that one is prone to doubt the negative testimony of experts.

It must be remembered that Buffalo is a long way from the coal fields, one hundred and twenty-five miles, and that distance adds to the difficulty. One company in Illinois is convinced that it does not pay to distribute more than fifty miles and decided to continue to operate two gas plants rather than concentrate on a single plant because that distance would be exceeded in that event. In that case the maximum pressure was about thirty pounds absolute. The Buffalo plan proposes to increase that to three hundred and seventy pounds.

However, it will be necessary to confront the facts, and these are that almost all the coal fields except the

anthracite region are obliged to compete with natural gas. Consequently the transmission of artificial gas through long distances seems almost inevitable if the gas is to reach a market not already monopolized by natural gas. If gas producing 1,000 British thermal units has rarely been transmitted long distances, there seems to be some valid reasons why artificial gas producing 537 British thermal units should find such transmission expensive especially in further view of the fact that natural gas being normally under high pressure requires less compression to make its delivery through pipes feasible. Leakage and the short life of wells perhaps account for hesitancy in building long gas lines but welding now makes leakage negligible even under high pressures and a line is being built from Shreveport to Beaumont, a distance of 210 miles.

According to G. S. Brewer, the authority mentioned, an investment of nearly two million dollars would be necessary if gas is to be transmitted to Buffalo through pipes from the nearest point in the coal field which is in the neighborhood of Reynoldsville, Pa. This investment *should* afford a profit of six per cent or not less than one hundred and twenty thousand dollars per annum, whereas, according to Mr. Brewer it cannot be figured to save more than sixty-six thousand. Such a prospect of meager profit would not find many takers.

However, looking at the figures contained in the article on p. 951 of this issue it will be seen that no consideration has been given to the storage of gas which would involve a considerable expenditure, perhaps \$300,000 if the manufacture were centered in Buffalo. The pipe line proposed would hold 518,375 cu.ft. at 370 lb. pressure or between twelve and thirteen million cubic feet figured at atmospheric pressure. This is an item not to be overlooked. It would iron out daily peaks quite satisfactorily. It must be remembered, however, that with twice that quantity being used per day in the winter it would not enable the plant at the mines to store in any one month enough gas to reduce perceptibly the needed production in another, nor would it make it feasible to reduce the diameter of the pipe. The pipe would serve merely as a gasometer. It would not function in any larger capacity, and speaking without careful inquiry, it might be found not as successful as a gasometer in meeting abnormal peaks.

Other advantages of a pipe line are that the coal would be carbonized where land is cheaper and where labor should be also. However, the disadvantage would be considerable in case of a strike or in case the area being mined should become exhausted. If pipes are to be used for the main transmission it would not do to have to haul coal to the plant by railroad and thus have a large portion of that expense the elimination of which was sought when the piping system was installed.

What Has Happened to Our Coal Dust?

NOTING the prevalence of explosions, ascribed as they usually are to coal dust, one begins to wonder what subtle change has taken place in the composition and condition of a substance that in early days was believed to be harmless and now is rightly regarded to be a chief cause of disaster.

The change is probably not so much in the dust as in other factors in explosions. True the dust is likely to be drier. We supply more air per man, we have

more men in the mines, and this air dries the dust. Our mines are deeper and therefore likely to be drier and a trifle warmer, the latter development being so slight that it only inconsiderably affects the dryness of the dust and therefore its explosibility. We are mining more extensively in dry, semi-arid and arid regions and in consequence the mines are drier. That doubtless had much to do with the Castlegate explosion and with the disasters at Dawson, N. M. The Western and Middle-Western coals also which are newer have more dangerous dust than Eastern mines.

Still with all these reasons arising from the nature of the dust why are we suddenly confronted with an increase in disasters such as we have had? There have been no incursions of ignorant foreigners on whom we used complacently to place the blame. Our mining population is more stable and experienced than in the past. There can be but two explanations—the mine-run scale of wages and more gas.

Now that the men are paid for all the coal they mine, large and small, they let powder do the work. They make more slack and dust and they use larger and thus more dangerous shots. But after all the principal cause of most of the recent explosions is gas. A small gas explosion occurs and is propagated by dust. The trouble is that our mines are gradually getting deeper. They possibly always had a little gas.

Without means to detect it no one knew it was there. Perhaps in some favorable part of the mine it might be induced even to burn. In mines that were closed up the methane emission was so slow and the formation of carbon dioxide so rapid that the mines when opened and not ventilated could be explored with a naked light without an explosion, though not without danger. The mines were said to be non-gaseous. Since then the operators, superintendents and foremen operating these mines have extended them under deeper cover.

Gradually they have become more gaseous but the progress has been slow toward recognizing the mines as really gassy operations. In fact accidents, larger or smaller, have dictated every move—first firebosses, then mixed lights, later abolition of smoking, then searches for matches, later permissible explosives, then a closed-light mine and yet again permissible machinery. There are more gradations than those mentioned and some of the changes were rather in the growth of discipline than in methods.

When men from non-gaseous mines went to gaseous they were mostly culpably lax. A superintendent, in a mine now operated by the Old Ben Coal Corporation, today one of the best conducted operations in the country, not so many years ago called attention of an editor of this paper to a blower proceeding from a shothole and before he could be restrained took a match and lighted it. It took some minutes of vigorous fanning with his cap to put the lambent flame out. Such superintendents are learning every day, but at what needless cost?

Times have changed conditions so much that we are wondering if all coal mines should not be rated as gaseous mines even at the risk of being a little unfair to some shallow, croppy operations. The disasters must cease. The industry must soon determine that the rank and file of mines must toe a common line. They are rapidly getting to be gaseous operations and that fact must be realized.

Twin-Rope Skip Hoist Works Well

Small Ropes Reduce First Cost of Installation, a Relatively Light Hoist Running at High Speed Thus Being Made Available—Two-Car Rotary Dump Cuts Down Payroll

BY ANDREWS ALLEN AND H. F. HEBLEY
Chicago, Ill.

USING two ropes of comparatively small diameter for hoisting coal skips containing eight to eleven tons of coal each is a somewhat novel practice that has fully justified its adoption at the recently completed Thermal No. 4 mine of the Donk Bros. Coal & Coke Co., in Madison County, Illinois. By this means, it has been possible to decrease the size of the drum upon which the ropes are wound and to use an engine smaller, though of higher speed, than would have been necessary had the ordinary single rope been installed. This decreased the initial cost of the installation. It constitutes, however, only one of several more or less radical departures from conventional practice adopted at this operation.

To some, interest in this plant may center in the layout of the shaft bottom, which was built around a two-car rotary dump that requires two less men for its operation than does the average cage-equipped mine of equal output. Others would be interested in the steel and concrete headframe, or in some of the various tippie refinements, such as the single-arm drive near the center of each shaker screen leaf and the triangular chutes that spread the coal from the screens evenly upon the picking tables.

This mine was designed to hoist 6,000 tons of coal per day, its capacity now amounting to between 3,000 and 3,500 tons. It was opened a few years ago and has been hoisting coal through the 2,000-ton-capacity auxiliary shaft since early in 1921. The first unit of this plant, including the first section of the power house, the various surface buildings and the auxiliary shaft tippie fitted with shaker screens designed to prepare lump and egg coal, also the overturning cages, were described in *Coal Age*, in the issue of June 9,

1921. During the summer of 1922 the company decided to complete the plant. This work was begun in September of that year and the first coal was hoisted from the main shaft and prepared at the main tippie on Oct. 11, 1923. The mine workings are still in process of development.

FURNISHES POWER TO ANOTHER COAL MINE

When the company decided that its entire plant at its No. 2 mine near Maryville, with the sole exception of the hoist, should be electrified by current from the power plant at No. 4 mine, the original design of that plant had to be modified slightly. The original selection of power units had to be changed and an outdoor step-up transfer station with a power line extending to No. 2 works had to be added.

In describing the plant at No. 4 mine, it will be advisable to consider it under four divisions: First, the tippie and preparation plant; second, the hoisting equipment; third, the bottom dumping station and, fourth, the power plant. The last division, however, will be considered separately in another article, which will appear next week.

The main tippie is designed for treating 6,000 tons of coal per day, preparing it in five sizes—6-in. lump; 6x3-in. egg; 3x2-in. No. 1 nut; 2x1½-in. No. 2 nut and 1½-in. slack, as well as various combinations of these sizes, all of which may be loaded direct. All sizes except slack will be carried into the cars over picking tables and loading booms. The clear height under the tippie is such that locomotives can pass under the tippie on any track. Degradation of prepared coal is avoided by the use of long loading booms which carefully lower the tippie product into the cars.

The arrangement of the yard necessitated the location of the through track for handling empties midway between the egg and No. 1 nut tracks. As the loco-

NOTE—The illustration used as a headpiece was made from a photograph taken from a point down track and shows not only the tippie structure but the "wine-glass" refuse bin and crusher shed. Both tippie and shed span six railroad tracks.

Skip Hoisted in Tippie Structure

The twin ropes and the equalizing sheave in the skip ball can be clearly seen. The concrete on three sides of the skip compartments protects the tippie from the shaft gases yet allows ready access to guides, buntons and the like.

necessary. In practice, four are employed on each lump table together with two pick men who break up the lumps of coal and gob so that the slate and bone may be dropped through a 6x6-in. grating into the gob conveyor, the coal being returned to the tables. The egg and nut tables usually employ four pickers each.

The gob conveyor consists of two parallel troughs, into which the burnable and unburnable pickings are sorted. The burnable material is taken by this conveyor to a bin adjacent to the shaft where it is crushed for use in the boiler house. The unburnable gob is delivered into a bin of the "wine-glass" type so situated that its contents may be discharged into a car standing on the No. 2 nut track below the end of the No. 2 nut loading boom.

The picking shed is entirely inclosed and provided with a line of windows across the end of the picking space. Consequently this portion of the building may be heated, and the pickers are well protected from the weather. The loading booms, however, extend into the open and are raised and lowered by counter-balanced, worm-gear hoists suspended from a steel-frame bridge situated down track but near the ends of the booms. The hoists raising and lowering these booms, however, are housed in a totally inclosed gallery.

INDIVIDUAL MOTORS DRIVE VARIOUS UNITS

All the various tippie units are fitted with individual motor drives equipped with helical gears and flexible couplings. The motors are operated from push-button control boards located in the picking shed over the engine track. Here the tippie man can overlook the operation of the entire tippie. Cars on the tracks are controlled by car retarders, and the booms are raised and lowered by the trimmer.

Down yard from the end of the loading booms is another structure spanning the tippie tracks. In this is installed a ring crusher mounted on skids. This machine may be moved into position opposite the end of the loading booms, the product from which may be crushed and loaded directly into a car. A small hopper is also mounted above the engine track so that a locomotive may be coaled with egg fuel which is held in this hopper for this purpose.

The tippie construction is heavy and rigid throughout. The shaker trusses are framed into the main structure instead of being carried on a separate support as is the usual practice. There is no sway to this structure and the vibration when the screens are running is barely perceptible. The tower above the shaft is of reinforced concrete up to a point 17 ft. above the rail. Above this elevation it is of structural steel, concreted on three sides, leaving the front entirely open thus affording ready access to the skip, guides, buntons, etc., and at the same time protecting the steel and the interior of the tippie from shaft gases and consequent deterioration.

The shaft is provided with overturning skips pivoted at the bottom and provided with latches to hold them in a vertical position within the shaft. They are operated by long-radius dumping angles at the top so as to afford an easy dumping cycle and diminish the drop given the coal during discharge. The dumping side of the skip is inclined at an angle of 30 deg. to the vertical, so that the skip has to overturn only 105 deg. in order to secure a 45 deg. angle for the flow of the coal. This inclination has been found sufficient in practice, and experience has shown that no excessive breakage of coal is incurred when a skip is operated in this manner.

The hoisting equipment includes a double-rope system which, so far as is known, is new in operations

Shaker Screens in Action

These screens are double-decked, but the details of greatest interest are the supports and the drive. Pendulum hangers support these screens, the latter being driven by single arms or connecting rods. The screen openings used are both circular and slotted.

of this kind. A 1-in. hoisting rope is employed, both ends of which are fastened to the drum. The two ropes then pass over a double-grooved sheave and around an equalizing sheave 3 ft. in diameter attached to the skip bail. This affords an excellent rope connection at the skip with an easily accessible arrangement for adjustment at the drum. The small rope diameter makes it possible to employ a cylindro-conical drum 5 to 7 ft. in diameter and a 24x42-in. hoisting engine operating at a fair speed.

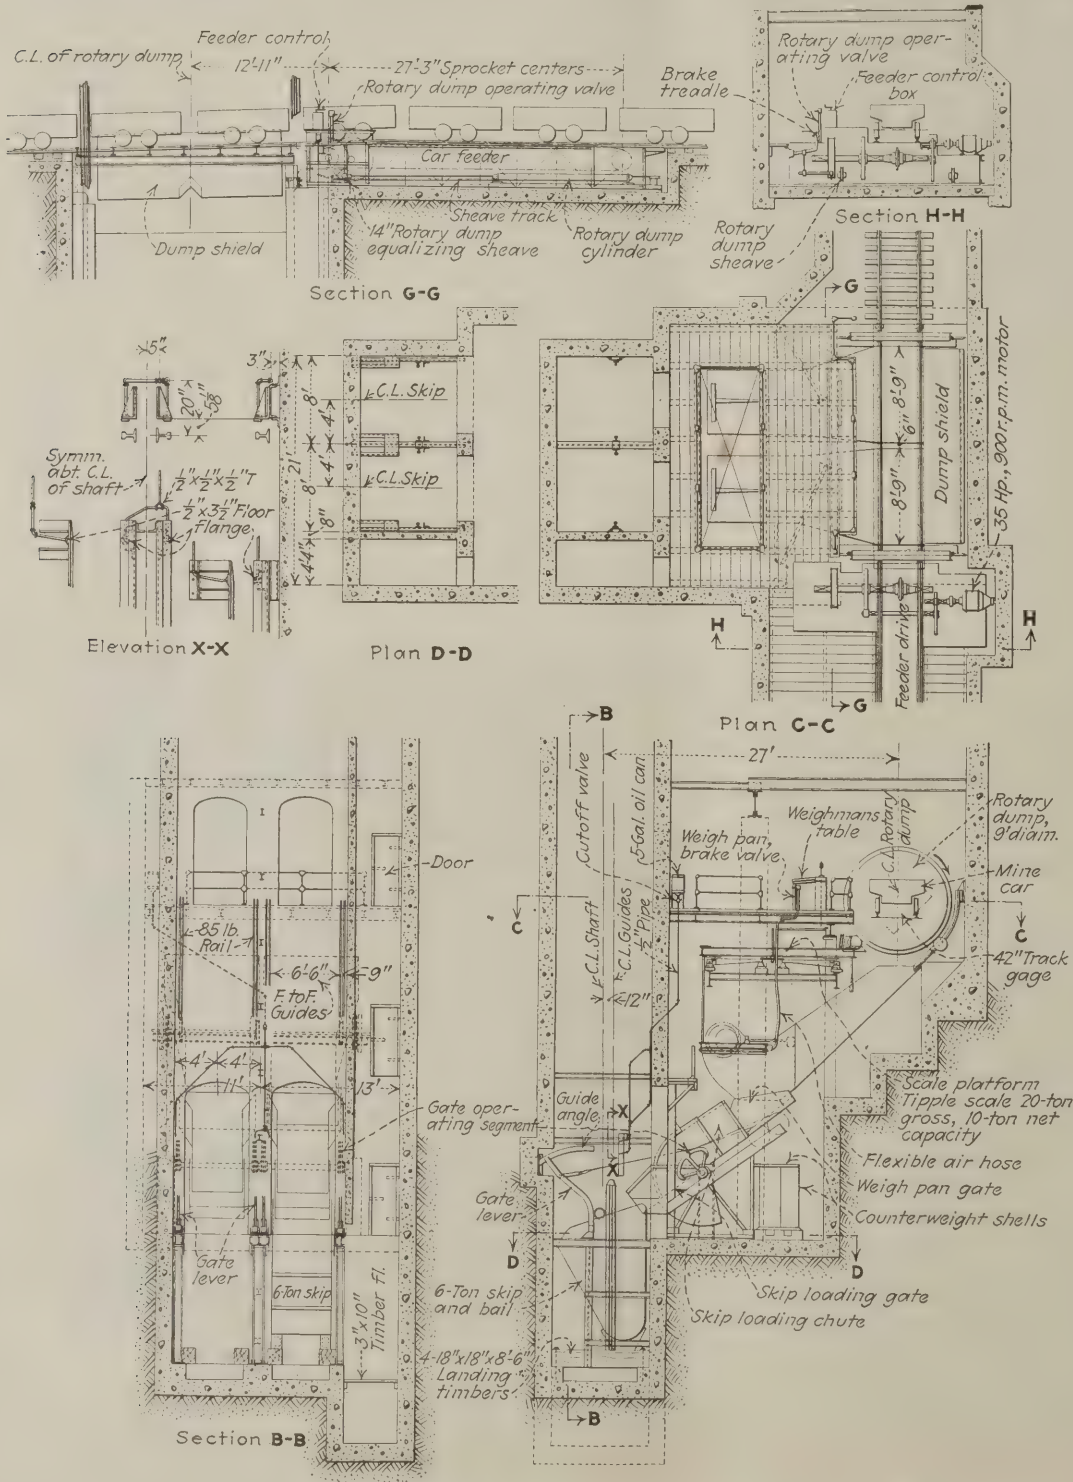

A single rope of equal strength would have been not less than 1½ in. in diameter and would have required a drum at least 8 ft. in diameter. This would have necessitated the installation of an engine of much slower speed and longer stroke entailing a considerably

increased first cost for the hoist. The double-rope system has afforded entire satisfaction in practice, and there is no reason why a similar system cannot be adopted at many operations especially those employing skip hoisting where speed is slow and the load heavy.

The skips have a nominal capacity of 320 cu ft., or about 8 tons of coal. They may, however, be surcharged without spill to a capacity of 10 or 11 tons. Each skip with its bail weighs a little less than 7 tons complete.

Exhaust steam from the hoisting engine is utilized for power purposes being passed through a pair of regenerators and a mixed-pressure turbine. These will be described in greater detail in the article on the power plant to appear later.

The mine is designed to use solid-end cars and

Shaft Bottom of Thermal Mine No. 4

Although the coal is dumped from the weighpan before the skip has landed, the gate in the skip chute is opened by the skip itself so that there is no spillage into the skip sump. As the skip starts to rise, also, this gate is closed so that it is unnecessary for the skip to remain standing until the last dribble of coal has run into it. This arrangement saves much time. The rotary dump handles two cars at a time. The skips will hold three cars of coal each but so far the regular loading has been only two cars or about 6 tons per skip. In the morning a single car is dumped in one weigh pan. At the next dumping two cars are discharged, one in each pan. The weigh pan with two carloads is discharged to the skip leaving one pan with no coal and the other with a carload. When the next two cars are dumped the pan with two carloads is discharged to the skip leaving the other pan ready to be discharged after the next dumping.

Pickers at Work on the Picking Tables

Four pickers and two pickmen on the lump table and four pickers on the egg table complete the usual complement of coal cleaners. This portion of the building is enclosed and may be heated. The loading booms, however, extend out into the weather.

overturning self-dumping cages at the auxiliary shaft. A two-car rotary dump is placed at the foot of the main shaft. The skips will hold three cars of coal each but so far have been regularly operated on a two-car basis. This gives a total load of about 6 tons per skip. The hoisting cycle at the present time actually consumes about 25 sec. This includes all the operations between hoists, about 8 sec. being consumed in loading the skip at the bottom. Cars are handled through the rotary dump in trips without uncoupling, the car hitchings employed embodying a swiveling spring drawhead at one end of the car and a single link between cars.

Cars are moved and spotted in the dump by means of a chain feeder about three car-lengths long. This is provided with lugs which engage lugs on the cars. Two sets of lugs are provided on the chain, one engaging the cars and one coming between them. Thus

should one set miss the car, the next set would pick up and carry the trip along without interruption.

This car feeder is operated by a 35-hp. motor fitted with a solenoid brake. A foot brake also is applied to the headshaft as an auxiliary. The grade on the bottom is 6 per cent against the loads; that on the feeder is $1\frac{1}{2}$ per cent adverse, while the grade on the dump is 2 per cent with the loads, this inclination being extended for some distance below the dump in order to string out the cars and put tension on all of the couplings so that the pins will not fall out during the dumping process. Below this 2 per cent section the grade is gradually flattened out to level, so that trips when cut off at the dump run easily and uniformly to the end of the empty track.

Trips are brought in from the mine by the main haulage motor and left on the main bottom. The locomotive then proceeds by way of a crosscut to the empty bottom where it picks up its trip of empties and returns to the mine. The trip of loads left on the bottom is taken by a shunter locomotive which operates on a track beside the single-track bottom. This moves the trip forward until its first car may be coupled onto the string of cars on the feeder.

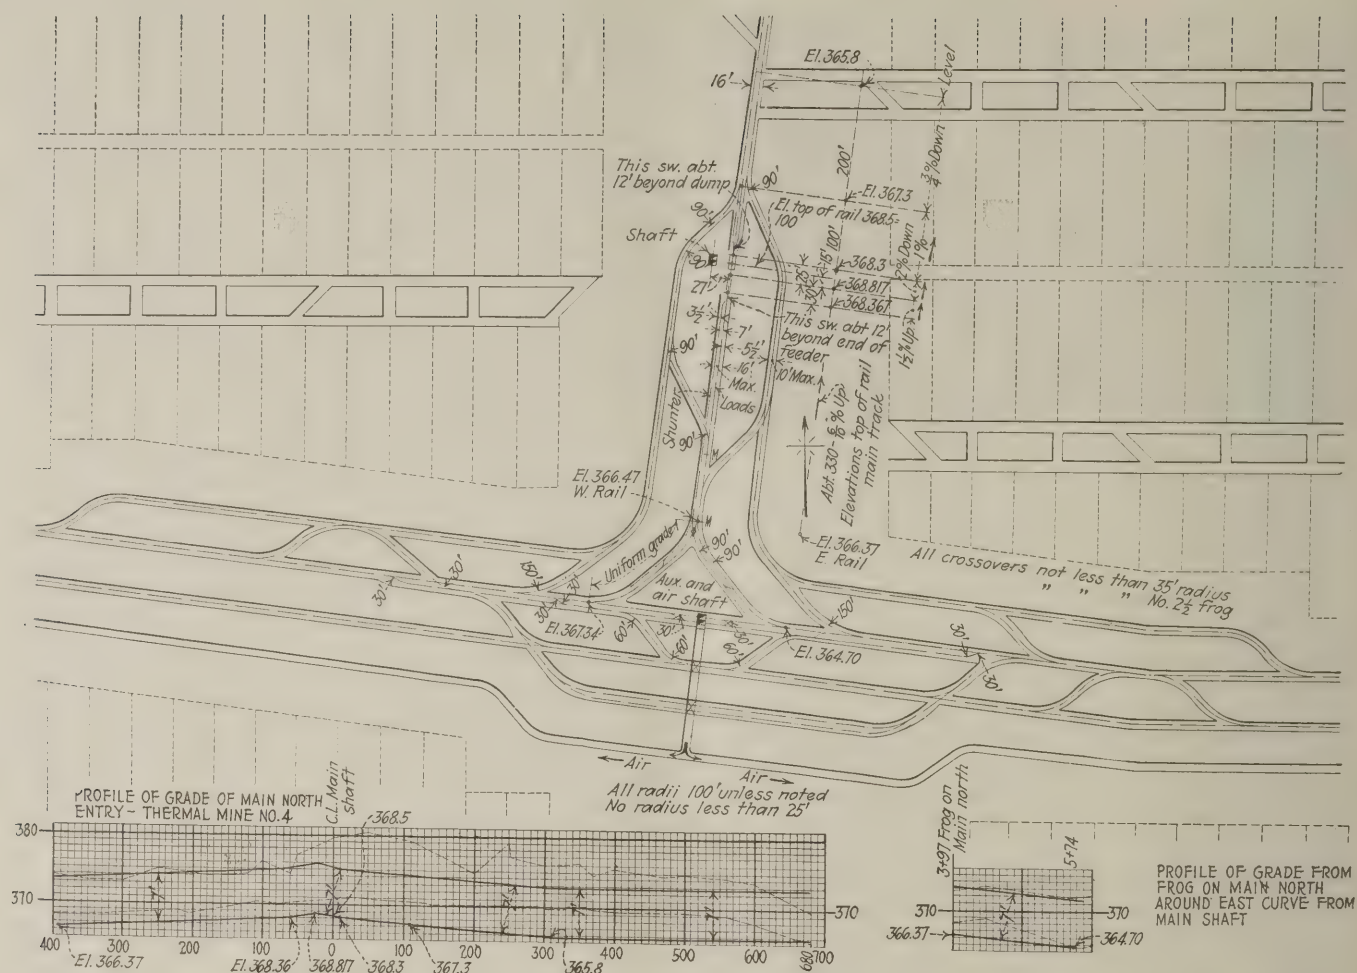

In this manner a continuous supply of cars is provided for the dump and feeder, and the whole string, sometimes as many as sixty cars at a time, is easily handled by the feeder. The trips are cut off just below the dump and a stop is provided so that the couplings may be slack when pins are to be pulled.

The car dump handles two cars at a time and is actuated by two air cylinders set horizontally in the shaft bottom alongside the feeder frame and under the floor. From the dump, coal from each car goes into a separate weigh pan. The second carload goes in on top of the first and is weighed with a double-beam scale. This scale is arranged for the ultimate installation of

Rotary Dump

This dump is air operated and controlled by one man, two cars being discharged at a time. It is unnecessary to uncouple the cars from the trip in order to dump their contents. The number of men employed at the bottom is thus appreciably reduced yet a steady stream of cars may be fed to the dump. Swivel couplings are of course used between cars which are of the solid-body type.

Bottom Layout of Thermal No. 4 Mine

Coal may be hoisted from either the main or auxiliary shafts, and the mine has been largely developed from this latter opening. Under ordinary circumstances, however, all hoisting will be done at the main shaft which is equipped to raise 6,000 tons per day. Careful planning was exercised in laying out this bottom.

either a weightograph or a self-recording device of some kind.

In ordinary manipulation, a single car is dumped in a weigh pan. On the next operation of the dump, two cars are discharged. This gives two carloads in one weigh pan and one in the other. From this time on, two cars are discharged at a time, and two loads of coal are ready for each skip as it lands. When three cars are handled in a skip the first car can either be dumped against the gate in the chute, or three carloads may be discharged successively into the pan and weighed cumulatively in the same manner as two cars. The weigh pan is of the ordinary gravity-operated type, with an air plunger to lift the brake weight.

When operating at maximum capacity, the weigh pan will be dumped as soon as the descending skip has passed the dumper level. The coal will thus reach the skip just as it lands. To prevent coal going into the sump and to avoid the necessity of holding the skip until the last dribble of coal has passed into it, a pivoted and counterweighted undercut gate has been placed at the lower end of the chute from the weigh pan to the skip. This gate is opened by the skip itself during the last 6 ft. of its descent. It is closed by a counterweight when the skip rises. This gate is provided with a discharge spout that projects over the side of the skip in the loading position and prevents spillage of coal between the chute and skip. At present the skip remains at the bottom only 8 sec. This time

interval, however, may be decreased as the operation of hoisting is speeded up.

All operations of handling coal on the bottom are performed by four men, a weighman, a check puller, a dumper who handles the feeder and the rotary dump, and a man on the shunter locomotive. In a cage-hoisting mine the weighman and check puller would be located in the tippie, leaving two men properly assigned to the bottom as against at least the four that would be needed for uncoupling, coupling and caging in a mine even approximately the size of this one if it were hoisting by means of cages.

It is anticipated also at this mine that the maintenance expense incurred in keeping cars in proper shape will be reduced at least 50 per cent on account of the solid-end construction and the easy manner in which these cars are handled at this operation.

The Donk Bros. Coal & Coke Co., owners of this property, is the largest company operating in the Standard District—or Belleville Field—of Illinois. This firm has now been in business for sixty years during which time it has controlled many coal properties. In addition to Thermal No. 4, it at present operates Maryville No. 2, with a capacity of 4,000 tons a day, and a coal washery with a capacity of 1,000 tons. The company also controls the St. Louis, Troy and Eastern R.R., on which coal is transported to the St. Louis market. Within this latter city and in East St. Louis, Ill., it operates fourteen retail coal yards.

Old Men More Subject Than Younger to Accidents

Habit Promotes Carelessness—Declining Activity Possible Cause of Accidents—Older Men Probably Succumb to Accidental Injuries—Men Who Have Had One Accident Liable to Have Another

BY THOMAS T. READ AND W. W. ADAMS*

IS THE new employee or the old and experienced one the more likely to suffer from accidents? is a question frequently asked at safety meetings. It is commonly thought that the new employee is the more liable to injury, because of his unfamiliarity with the hazards of his new job. On the other hand, it is often claimed that the man's very unfamiliarity impels him to use greater caution, which should compensate or more than compensate for his inexperience.

Again, it is argued that the old employee will avoid hazards through habit; but others claim that habit will more often cause a man to ignore hazards that would attract the attention of a less familiar workman who is conscious of his danger.

As a simple illustration of the latter argument, compare the two ways in which a small child and a grown person will button their clothes. The grown person, by force of habit gives no attention to what he is doing and fails to notice a needle left sticking in the buttonhole. On the other hand a child performing the same operation with conscious attention to each button and hole is more likely to see the needle and remove it before being hurt.

Doubtless there is truth in all these arguments, but their relative weight cannot now be determined, because we do not have sufficient statistical data from which to argue. Evidence supporting the view that accident frequently increases with the age of the individual and, presumably also, with his experience and length of service, is furnished by certain statistical data relating to fatalities among coal miners in England and Wales.

Statistics covering three three-year periods, 1890-92, 1900-02, and 1910-12, taken from the report of the Registrar General, Great Britain, show that accidental deaths are not only more frequent among the older miners employed in the mines, but fatalities are likewise more frequent among the older men engaged in other industries than mining. The latter fact is rather more surprising than the former, because older men, being less active and presumably, leading a more quiet mode of life, might be expected to meet with fewer hazards, considering all occupations. It is probable, however, that this factor is more than counterbalanced by the lesser degree of alertness of the older men.

Apparently a younger man, though engaging in

sports and activities making him liable to occasional injury, is yet able to escape under circumstances that might result in accident to an older man. The alertness of the younger and more active man seemingly more than compensates for the less active and therefore less hazardous occupation of the older class of workmen.

This view is further strengthened by the higher fatality rates among the older employees in mines.

The figures compiled from the reports of the Registrar General show that older miners almost invariably meet with a larger number of fatal accidents than younger men. The fatality rate for men about sixty-five years of age, for example, may be seven times as high as that for men under twenty-five years of age. In Table I are given the fatality rates, per thousand men,

in each respective age group indicated in the left-hand column. The rates are further classified as mine accidents and accidents in other industries.

One point not shown by these figures is the character of mining work performed by men of different ages. It is possible that many of the younger men are new employees, and hence are not assigned to the more hazardous jobs in the mines, until they have acquired the necessary experience to perform the work with a reasonable degree of safety.

Another point not considered is the lower bodily resistance of the older men, which may cause them to succumb to an injury from which a younger man might quickly recover. In the absence of evidence on these two points, however, the record indicates that, in the coal mines of England and Wales at least, fatality rates are higher among the older and presumably, more experienced employees.

Another factor that has attracted little attention as yet is what may properly be called the "personal accident hazard." This is recognized, to some extent at least, in the axiomatic phrase, "the best accident pre-

BORN UNDER AN UNLUCKY STAR

Though constellations and their groupings have nothing to do with the lives of men, the old belief is that there are individuals subject to unusual personal hazards who find danger even in relatively safe occupations. They are not necessarily reckless but may be temperamentally unable to scent danger or slow to avoid it. Most of us as years increase and strength declines fall under the influence of the unlucky star. Some men, for instance, are notoriously unsafe in the saddle and some become so with increasing years.

Table I—Fatality Rates of Miners in Great Britain
By Age Groups

Age Group	Mine Fatalities			Fatalities of Others		
	1890-92	1900-02	1910-12	1890-92	1900-02	1910-12
15-20.....	1.5	1.1	1.1	..	0.1	0.2
20-25.....	1.3	1.0	1.1	0.2	0.2	0.2
25-35.....	1.6	1.1	1.2	0.2	0.1	0.2
35-45.....	1.8	1.4	1.3	0.3	0.2	0.3
45-55.....	2.4	1.7	1.4	0.5	0.4	0.5

NOTE—Published by permission of the Director, U. S. Bureau of Mines.
*Acting assistant to the director and statistician, respectively.

ventive is a careful man." It is probable, however, that this phrase implies, in the minds of most people, that any man who wishes can put himself in that category and so eliminate most of his accident hazards. But such reasoning is faulty. A deaf or blind man has a personal accident hazard owing to his disability, and no amount of care on his part will serve to eliminate though it will lessen the degree of hazard. There is good reason to suppose the existence of other personal characteristics that, though less evident than blindness or deafness, still constitute true accident hazards.

The only statistical studies that throw any light on this matter are those made by Karl Marbe, professor in the University of Würzburg, in an effort to support his hypothesis that a man's liability to accident can be measured by the number of accidents he has already experienced. The studies are based on the records of an insurance company that insured commissioned and non-commissioned officers in the German army against accidents of any kind.

Three thousand individuals, taken at random from among those who had been insured for ten years or more, were selected and their individual accident records plotted and compared. These were divided into three groups as follows: (a) Persons who had had no accidents in the first five years of their insurance period, (b) Those who had had but one accident in this period, (c) Those who had had several accidents in the same period. The average number of accidents for each group for the second five years was then computed, and is as in Table II.

Table II—Average Number of Accidents in Second Five-Year Period

(Of men grouped by accidents in first five-year period)

Group A (No accident in first five-year period).....	0.52
Group B (One accident in first five-year period).....	0.91
Group C (More than one accident in first five-year period)....	1.34

In other words, a man who has had an accident in his first five-year period is nearly twice as likely as a man who had no accident in the first five years to have an accident in his second five-year period. A man who had more than one accident in the first five years is more than 2½ times as liable to accident in the second five years as the man who had no accident in the first five years.

This computation was checked by dividing the same individuals into two groups: (a) Those who had no accidents in the first two years of the insurance period and (b) Those who had one or more accidents in the first two years. Computing the average accident rate during the last two years of the insurance period for each of these groups, they compare as in Table III.

Table III—Average Number of Accidents in Last Two Years of Insurance Period

(Of men grouped by accidents in first two years)

Group A (No accidents in first two-year period).....	0.24
Group B (One or more accidents in the first two-year period)....	0.42

In other words, a man who has had an accident in the first two years of his insurance period is, approximately, twice as likely to have an accident in the last two years as is a man who had no accident in the first two years of the same period.

The question immediately arises, however, as to whether the persons injured in the first two-year and five-year periods were not engaged in occupations

involving a greater hazard than those in which the persons who had no accidents in that period were engaged. For the purpose of checking this the individuals were divided into three classes of hazards; namely, the first class included bureau employees engaged in office work, the second those employees on foreign duties, the third class embracing those engaged in especially dangerous duties. Analyzing each of these classes it was again found that the persons who had accidents in the first two or five years of their insurance period were more liable to accident in the second or last two or five years of the insurance period.

The possibility of hazard outside of the occupation of the individual, such as habitually engaging in certain forms of sport, was also investigated statistically, and this method also confirmed the first general conclusion that people who have had accidents are more liable to have more.

The conclusion Professor Marbe draws from his study is whenever a man has an accident his insurance premium against subsequent accidents should be increased. A more important conclusion with respect to accident prevention, however, is the obvious necessity for increased care on the part of those who have had accidents. It is perhaps too generally supposed that an accident automatically makes a person more careful; but it is at least doubtful whether this is true. It seems safe to conclude from the statistical studies that when a man has had an accident it is, on the average, a notice to him that he needs to take unusual care to prevent future accidents.

British Also Taking Stock of Resources

GREAT BRITAIN is re-acquiring apparently that interest in industry that marked the end of the eighteenth century and the beginning of the nineteenth. With the Archbishop of Canterbury sinking the first pick into the downcast shaft of the Betteshanger Colliery and the Prince of Wales writing a foreword to the book on "Fuel," recently contributed to the Resources of the Empire Series, we see a revival of that interest in industry which made an England of an earlier day known as a "Nation of Shopkeepers." Our Canadian friends likewise have held celebrations as significant at the opening of briquetting works. For the volume on "Fuel" about to be reviewed not only the Prince of Wales but Sir Eric Geddes and Sir Robert A. Hadfield have written introductions. All of which open up on a book with 83 pp. on coal, lignite and peat, 15 on carbonization, synthetic processes and carbonaceous wastes, 67 on petroleum and 6 on power alcohol.

The first section on coal, lignite and peat is by Professor Henry Louis, a well recognized authority in the coal industry. However we fear an American reader will be somewhat dissatisfied because the analyses given are relatively few and not detailed as to origin though they are given much space. In justification it must be acknowledged that the British government has provided no such storehouses of information relative to analyses as has been afforded by U. S. Bureau of Mines.

In a country like Great Britain where the coals vary in volatile matter with depth and igneous intrusions if more analyses were given it would be easier to ascertain the range of carbonization in any one district. The book is issued by Ernest Benn, Ltd., of 8 Bouverie St., London, England, measures 7½x10½ in. and contains 208 pp.

Technical Sessions, Illinois Mining Institute

Tracy Describes the Twin Agents of Death—Open Door and Open Light — McCoy Tells How He and His High-School Boys Have Developed Telephony — Farnham Relates How India Mines Coal

THE OPEN light and the open door are the "twins" which endanger coal mining most seriously, said Mr. Tracy in an address on mine explosion causes and remedies before the Illinois Mining Institute. He attacked black powder as having killed 857 men in seventy-one United States explosions. Permissibles, properly used, he holds would greatly reduce accidents. The "twins" of the open miners' light and the carelessly opened door which shortcircuits mine air are most dangerous between Saturday at 6 p.m. and the following Monday morning at 8, and therefore should be guarded against during those hours most scrupulously. Bureau of Mines statistics show they have caused the deaths of 2,300 men.

The open door, so often left open by plain carelessness, is one reason why no mine is safe. Mr. Tracy said the fact that an ordinary safety lamp may not detect gas is no proof that the mine cannot have a gas explosion. Such a lamp cannot detect gas in a quantity less than one per cent. But even 0.03 per cent of gas, if allowed to accumulate during a period such as a week-end, especially by short circuiting of air, rolls up in sufficient volume to make trouble. There have been explosions by gas in mines which normally generate only that small volume.

He advocated the use of permissible explosives, more comprehensive state laws that would require the service of mine examiners with territories small enough to be carefully covered, and greater care by miners, fewer doors to give opportunity for accidental short circuits of air, the use of methane detectors, not lamps, in gas tests and the maintenance at every mine of auxiliary power for ventilating fans. He spoke favorably of the new code of safety accepted by the operators of Utah, following the Castle Gate disaster, which takes effect July 1.

President D. D. Wilcox, remarked that Utah is not likely to live up to the new stringent code very long. The mutual effect of the explosion at Castle Gate is about like that caused by the Cherry mine disaster in Illinois in 1908. In that year Illinois adopted some impracticable regulations, many of which are not enforced.

NOTE—The meeting was described in last week's issue, p. 917.

First Locomotive at an Indian Coal Mine

The Goodman company delivered this electric trinket to the Tata Iron & Steel Co. for use in its Jamadoba colliery in the Jheria field, about 180 miles northwest of Calcutta only eighteen months ago. It helped mark the transition in Indian mining from the primitive to the modern. The transition is slow but is getting a good start in the mines of one or two companies.

Indian Type of Loading Machinery

The common practice in India is to hoist coal out whenever labor is available and dump it on the ground until orders are received for shipment. When these come, the usual method of transporting coal from pile to car is by women like these, with baskets big enough to hold about 75 lb.

A discussion of the relative merits of black powder and permissibles followed in which Thomas English raised the point: Why does the Bureau of Mines advise the use of no more than 1½ lb. of permissible per hole, answering it by saying a greater quantity would generate too much carbon monoxide.

The story of the first real success in radio communication between the surface and the inside of a coal mine by ground conduction was told the Institute by A. B. McCall of the Springfield high school faculty and consulting engineer for the Bureau of Mines. He told the story of how he and the radio club of the high school had interested themselves in the problem and how they got the results at the Woodside mine near Springfield that have attracted the attention not only of the state department of mines and minerals but of the Bureau. A descriptive article on their work will appear in *Coal Age*.

SINK ELECTRODES BELOW GROUND WATER

The method they have developed depends upon vertical transmission of voice currents between a pair of electrodes sunk 15 or 20 ft. into the surface over a mine and another pair in the mine, each pair connected to a 39½-lb. telephonic set. The ground is almost constant and forms an excellent conductor unless thick deposits of metal ores or a heavy volume of water intervenes. These conditions will seldom be met in coal and were not encountered at the Woodside mine. There, the surface electrodes were sunk below the ground-water zone and easy communication established with a set underground. It was determined that the line of the underground electrodes should parallel that of the electrodes on the surface but that audibility can be secured with variations up to an angle of 60 deg.

The practical application of the method to assure communication between the top and entombed but not incapacitated miners caught by explosion or fire, would require the maintenance of such sets in refuge chambers in various sections of a mine. Pairs of electrodes would then be maintained on the surface to which

High-Grade Technical Men at an Indian Mine

This is the type of workmen that has to be depended upon to do much of the development of Indian coal mining from the primitive to the modern. The gentleman in the center wearing a black turban is the chief electrician at one colliery. However the equipment is nearly foolproof and is successfully operated by the natives after a little training.

a portable set duplicating those in the mine could be attached at any moment during an emergency.

NO WIRES OR RAILS USED IN CONDUCTING LINE

Previous radio communication with underground places have depended largely upon the presence of wires, rails or other metallic conductors, Mr. McCoy said, even though breaks might have existed in such conducting lines. This new system depends upon ground conduction alone and can be operated at depths limited by the distance between the electrodes of each surface pair. Mr. McCoy and his high-school boys learned that the operating depth can be up to five times the distance between electrodes. The experimenters hope to carry their work farther and prove the value of other radio circuits which will further simplify the already simple one that has been used successfully at Woodside mine.

Coal mining in India proved a most interesting and somewhat amusing process to the Institute as pictured in word and slide by S. W. Farnham of the Goodman Mfg. Co. While a storm raged outside sweeping chairs off the deck and eventually driving the boat to tie up for an hour, Mr. Farnham spoke of the immense deposits of India, especially of the Jharia and Raniganj fields where many beds exist, some of them 20 ft. or more thick, the mining methods in which have been most primitive.

WIFE AND FAMILY HELP HUSBAND UNDERGROUND

In the Jharia field the thickness of the coal is no less than 200 ft. so that a big mine could operate for years under a surface of not more than 40 acres. The miners are of the agricultural caste and mine and load coal only between crop seasons and at 32c. a ton, each man taking his wife and probably his whole family

Modern Coal-Mine Top Works in India

The plants at two mines are shown in this picture. They are close together because the coal deposits under some of the land in the Jharia and Raniganj fields often total 200 ft. in several workable seams. Thus a tract of 40 acres often has enough coal in it to justify the erection of an expensive and permanent top plant. The men in the foreground are part of the electrical gang of the mine.

down into the mine with him while he is at work. Ventilation such as American miners get would not be endured by the Indian who fears catching cold from fresh air underground. The result is mine atmospheres are usually foul but entirely satisfactory to the Indian while he gets out his 1½ tons a day which is pushed out of the mine by the women in 1,200-lb. "tubs" or larry cars at a haulage cost to the mine owner of five cents a ton. Most of the coal from both slope, shaft or strip mines is dumped on the surface as fast as the operator can get men to mine it. It is loaded onto railroad cars by women with baskets whenever there is a shipment to be made.

In underground mining the best practice calls for the driving of 12-ft. entries dividing the coal into blocks which are removed on a retreating basis so that extraction often is high. Usual practice at those mines which are near rivers is to flush sand into the worked-out areas thus supporting the roof behind the active operations.

But coal mining in India recently has been turning to more modern and bigger-scale methods, he said. The first electric locomotive was put to work in the fields only 18 months ago. Skip hoists are being installed in a few mines and the haulage equipment is steadily getting larger.

Removed Ventilating Tubes at Gartshore And Explosion Resulted

IN GREAT BRITAIN the reports on mine explosions come long after the event, perhaps because the inquiry is quite thorough but more often for reasons that extenuate rather than explain. The report on the Gartshore explosion has just come to hand though it occurred as long ago as July 28 of last year. The official inquiry was held at Glasgow, Jan. 23-24, and twenty-two witnesses were called. It appears that at this colliery, which is in Dumbartonshire, Scotland, a 6x8 ft. roadway had been driven for use as a sump from the bottom of a shaft 558 ft. deep. The roadway was 590 ft. long and crossed three pitching seams of coal. It was driven quite crookedly, so much so that it almost returned on itself. It was ventilated by a pipe of 17-in. diameter which carried air from the return current of the mine to the face of the roadway, about 3,000 cu.ft. of air being thus delivered. Naked lights were used, but a flame safety lamp was kept burning near the roof at the face.

The ventilating pipes were removed from the face outwards as soon as steel girders and brick walls had been erected to support the roof and sides. Walls were being erected near the mouth of the roadway when an explosion occurred killing eight men and injuring two. Safety lamps, a cap with an acetylene lamp attached, a cap with a "naked-light" lamp attached and a can containing calcium carbide were taken from the sump-road 20 ft. from the mouth. The use of ventilating pipes in Great Britain, the danger of withdrawing them before a positive air circuit is provided for their replacement and the deliberate way the British follow up even minor accidents are interesting features in the record.

IN SPITE of heartbreaking obstacles in the path of underground loading, there's Joy among the loading machine men.

Sleeve Bearing Keeps Oil From Spattering Motor

Oil and Dust Carrying Bearing Lubricant Causes Electrical Equipment Failures—Bearing Excludes Dirt and Prevents Oil Leakage

BY R. PRUGER*

LEAKAGE of oil from the housings of bearings is rather a common source of trouble not only in the case of electric motors but wherever machinery is used. However, as long as no damage results from such leakage, a little attention on the part of the operator will take care of any escaping oil and keep the installation neat and clean.

With electrical machinery, however, the trouble is far more serious, the escaping oil easily reaches the windings or commutator and finally causes a short circuit or other serious damage to the machine. This may interrupt operation and entail expense for repairs. It will also result in considerable waste of lubricant, which is quite an item where a large number of motors are used. Fig. 1 shows how leakage occurs.

In order to remedy such defects, a "sealed-sleeve" bearing has been designed. If a perfect air seal can be maintained, that is, if the air cannot get in, it is obvious that the oil cannot get out. Preventing air currents from passing through the housing should, therefore, eliminate the leakage.

HOUSING MADE ALMOST WHOLLY AIRTIGHT

Though it is not possible to maintain an absolutely air-sealed housing, yet the design can be made such that it will approach this condition, and when further supplemented by mechanical devices, for the purpose of taking care of what little oil might still get out, a housing can be made which permits operating at high speeds despite the resultant air suction set up by adjacent ventilating blades and other moving parts.

This has been accomplished in the design as shown in Fig. 2. It may be noted that the bearing shell itself was not changed but remained standard, thus being interchangeable with bearings formerly used. The housing, however, is of a new type.

The cover, ordinarily found at the outside of the

*Motor Engineering Department, Westinghouse Electric and Manufacturing Co., East Pittsburgh, Pa.

Fig. 1—Motor Bearing of Conventional Design

Note the openings in the housing through which air and dust can enter the bearing, mix with the oil and be carried into the motor windings.

Fig. 2—Motor Bearing with Sealed Sleeve

This illustration shows how effectively this bearing is sealed against the entrance of air or dust and prevents the leakage of oil or oily vapor into the motor.

housing, that closes the opening through which the oil ring is admitted, was placed on the inside of the housing. This cover need not be removed, except for changing the bearing. This new location has the advantage that it permits the cover itself to be carefully bolted down, fully compressing the packing under it. As it is thus practically out of reach on the assembled motor, no one is likely to attempt to remove it.

For the purpose of inspecting the oil ring, a large pipe plug has been placed on the outside end of the housing. This plug can be removed easily and put back into place, air tight, with equal ease.

The dowel pin, which ordinarily keeps the bearing from turning and which is inserted from the outside wall of the housing, has been placed on the inside of the housing directly accessible through the pipe plug hole. Any sucking action has thus been rendered harmless, as it will be within the housing itself.

SHOULD NOT BECOME EVEN OIL SOAKED

The drain plug usually found at the lower part of the housing has been omitted. Such a plug certainly should not leak oil but that is not enough, it should not even become oil-coated. The effect of air currents passing over wetted surfaces and carrying oil vapors into the machine has been found quite an objectionable feature. For this reason every effort has been made to omit wherever possible all tapped holes, as it is found that pipe plugs below the oil level will leak. Even if plugged correctly at first, frequent unscrewing and oftentimes careless replacing will cause a small leak. This results in large wetted surfaces over which the intruding air passes. Experience has shown that a sealed housing which does not permit the air to enter will also exclude dirt and dust. With grinding of bearings, due to dirt in the oil, eliminated, the life of the bearing and the periods between changing of oil may be lengthened considerably.

Inasmuch as the shaft of an electric motor has a certain amount of end play, which at times may become quite pronounced, the shaft, when moving toward the inside of the housing becomes wetted by the oil vapors in the housing. On its outward movement this wetted surface is exposed, and at high speeds, small particles of oil are thrown off. As in the previous case, air currents pick up these particles and carry them into the

motor, where they are deposited upon the windings. It has been shown that on motors running at 3,600 r.p.m., this feature resulted in covering windings and adjacent parts with a film of oil within a few days' operation.

In order to eliminate this defect, a conical collar, forming a seal and acting as an oil thrower, has been placed upon the shaft on the inside of the housing of 3,600 r.p.m. machines. This collar is slotted to permit its being held on the shaft by reason of its own spring or clamping action, which permits automatic adjustment. This collar runs in a stationary cone-shaped piece of the same cone angle, leaving a small running clearance between the two conical surfaces. Any oil vapor reaching this clearance space is held there by capillarity when the machine is at rest and is quickly pulled toward the inside of the housing by centrifugal force when the motor is in operation and is thrown off by the lip of the revolving cone.

The oil thus thrown off is deposited on the inside of housing walls, where it is free to run downward. For this reason, the stationary cone is provided with a groove which guides the oil back into the oil well.

A similar action takes place on the inside end of the housing. Here, however, the shaft is provided with oil throwers of standard design, permitting the use of standard rotors the same as on the old standard machines. Again, the same action of small particles of oil being thrown off when shaft end play takes place is found. Such small quantities of oil as are thrown off at that point are caught by the outer chamber of the housing cap and rendered harmless. The soft felt washer placed on the inside and the soft felt lining in the outer chamber absorb this small quantity of oil and lead it back by capillarity into the oil well.

Soft felt washers at either end of the housing are primarily for the purpose of making the housing dust-proof and not to prevent oil leakage. In very dirty places, a double chamber cap, such as shown on the inside end of the housing, may also be provided at the outside end. Very fine dirt or grit deposited upon the shaft may find its way into the housing once it is worked under the felt by the end play. However, when the cap is provided with a double chamber, any dust

deposited upon the shaft can reach only up to the cap, and the shaft surface next to the felt washer and within this outer chamber is thus protected from any deposit. This, however, is found necessary only in very dirty places where much fine hard grit is found suspended in the air.

CIRCUMVENTING SUCTION OF FAN BLADES

As the action of fan blades and blowers driven at high speeds by the motor sets up quite a vacuum next to the inside end of the housing, it is obvious that this vacuum is communicated to the space within the housing itself, as it is impossible to seal the housing absolutely on account of the shaft passing through. As a result of the housing being divided into several separate chambers by the bearing supports, unbalanced air pressure may result in case the oil level is high enough to close the lower cored openings. It is for this reason that a cored channel which establishes communication between the chambers, thus balancing the air pressure, is provided at the top part of the housing, for the oil level next to the inside end of the housing may be raised if a vacuum greater than that found elsewhere in the housing exists.

At high speed, the action of the oil ring frequently sets up a surging of the oil, forcing it in the direction of rotation of the ring, which action may cause a slight overflowing at the overflow plug. This may be prevented by means of baffles which are cast into the housing and form a quiet level in the chamber next to the overflow plug.

It will be observed that where soft felt washers, such as are shown at the outside end of housing, are used, the metal cap has an inside bore diameter of at least $\frac{1}{4}$ in. larger than the shaft diameter, which is for the purpose of lending resilience to the soft felt. If the felt were compressed at a point close to the shaft, it would in a short time wear out, becoming glazed and hardened, causing it to burn and char. Soft felt of a good quality, if left free to expand, will act somewhat like a brush, and wear almost indefinitely, accomplishing its function as dust protector.

It is sometimes found, that machine operators fill the housing by removing the plug at the top. This is in-

Fig. 3 — New Type Bearing

Although this bearing has been in service for many months, there is no leakage of oil into the motor, the shaft being actually rusty.

Fig. 4 — Dust-Covered Motor

This squirrel-cage motor has been operating continuously in severe machine-tool service for nearly a year with no oil being added to the bearings. The dust covering the bearing is perfectly dry and can be blown off easily.

correct and unless the overflow plug is watched closely when filling, the oil level may rise so rapidly that it may also overflow into the motor through the housing bore. The soft felt washer located at the face of the housing prevents this overflowing effectively for a long enough time that the oil can find its level.

FREEDOM FROM DIRT PROLONGS LIFE OF OIL

This type of bearing requires practically no attention, and it has been found that it is best to postpone oiling until the need for it becomes apparent. This may be due to the natural breaking down of the oil or to dirt which may eventually become mixed with the lubricant.

It is always advisable to renew the oil soon after a new motor has been put into service to make sure of

getting rid of core sand. Though the motor manufacturer removes as much of this as possible, some of the recesses in the housing may contain hard deposits which, when softened by the oil, become loosened. A test sample, drawn out of the oil reservoir by means of a small pump, would soon disclose this fact.

It has been proved that the sealed-sleeve bearing requires less attention than is now common with electric motor operation, and in fact an occasional inspection is sufficient to convince the operator that the proper oil level is being maintained and that no refilling is required. Operating conditions and quality of lubricant used will easily set the period required for oil renewals, which may be from three to six months or even longer. A good grade of light machine oil is preferred for use with the leak-proof sleeve bearing.

How to Ground Electrical Mining Machinery

With Bonded Track or Pipe Beware Lest Changes Destroy Ground — Interconnect Pipes Electrically — With Gathering Pumps Do Not Rely on Pipe

BY CHARLES M. MEANS
Consulting Engineer, Pittsburgh, Pa.

THE IMPORTANCE of grounding the frames, bed-plates and all metallic non-current carrying parts of stationary electrical equipment is fully evidenced by the fact that all safety rules require it. It is doubly important, when we are dealing with underground equipment because of the character of the surroundings. Close adherence to the rules for grounding is strictly necessary for all power equipment, regardless of the voltage of the circuit to which such equipment is connected.

The object of grounding is to maintain all metallic non-current carrying parts at zero potential or at the same potential as the surrounding earth. In order to create this condition such parts must be in intimate contact with the earth.

This naturally brings us to the problem of what can be considered an adequate ground connection and how to obtain it in a mine. The conditions existing in coal mines vary between wide limits and no definite rules for grounding can be laid down that will fit every case.

Where a well-bonded track or a relatively long pipe line laid on the bottom is available, the problem is not difficult of solution. But it is important to know that the track is not likely to be disturbed or the pipe line broken near the point where the ground is attached. This, however, is a problem of maintenance, for the permanency of the ground is dependent on inspection and upkeep.

When equipment is located remote from a bonded track or a pipe line, the problem may involve difficulties. In many mines the roof and bottom may be quite dry and therefore act as an insulator. Under such conditions it will be difficult to secure an adequate ground; but in turn the hazard involved under such conditions is likely to be of less consequence than in wet places.

It should be the rule, nevertheless, to apply a good ground to all stationary equipment, no matter where located. It may be necessary to run the ground wire a long distance to obtain an adequate connection to the earth. Such a wire should be run on insulating supports and in no case be allowed to lie on the bottom

NOTE—Article entitled "The Grounding of Electrical Mining Machinery" delivered at meeting of West Virginia Coal Mining Institute, Elkins, W. Va., June 17-18.

along the entries, or in contact with the sides of roof.

The method of installing the ground connection is important. It should receive the same care as the line wires. The wire should be accessible and in plain view at all times to admit of ready inspection. Its size can be determined by local conditions but should never be smaller than No. 6.

GIVE GROUND CONNECTION SAME CARE AS FEEDERS

In underground substations great care should be taken to provide adequate ground connection. It is to the interest of safety to provide more than one ground connection from all equipment so located. The ground wire may be soldered, brazed or otherwise connected to the machine in lugs that are held by clamps, bolts or studs. The frames and bedplates of motors and generators, all supporting metallic frames on the switchboards or controlling devices, as well as the metallic covering of all cables, should be connected to the earth or grounded return.

Motors and controls used to operate permanently located pumps should be treated in the manner described for substations. In pump rooms, however, the difficulty of securing a permanent ground is somewhat lessened by the presence of pipe lines which can be used for the purpose—but the ground connection should include interconnection of all pipe lines, either through the ground wire or by permanently connecting the pipes.

Gathering pumps present a somewhat different problem, and each case must be handled as conditions warrant. In general it is safest to run an independent line to a permanent ground from the suction or discharge line. This practice eliminates the possibility of shock when disconnecting pipe lines and is imperative where wood or fiber water lines are used. In many cases, where the motor and control is mounted on the same base as the pump, the elements of safety will be met by eliminating the ground connection entirely.

BEWARE OF STOPS ON HEAVILY SANDED RAIL

Trolley locomotives come under the head of portable equipment and are under all ordinary circumstances in intimate contact with a bonded track which answers every purpose of a proper ground. Exceptions to this assumption arise when the locomotive stops on a heavily sanded rail or is run onto a section of track that is not bonded. Both of these exceptions are the result of operating conditions that should not be allowed to exist.

The storage-battery locomotive represents a type of electrical equipment that does not require a ground connection, as its electrical circuit is complete within itself and should be insulated from the frame.

With machines for mining, loading, drilling and conveying coal, an entirely different problem has to be met, and one that does not always find a practicable solution. The legal requirements of certain foreign countries demand the grounding of frames of mining machines, but that is not required in this country.

It is a fact that in certain mines a hazard is created by not grounding the frames, but in most mines very little if anything is to be gained, for a ground wire might be a source of danger. When we speak of mining machines, we naturally think of the shortwall type which is in general use. While cutting across the face or being dragged to or from the truck the frame is in intimate contact with the earth.

There may be exceptions to this case. The frame

may happen to be insulated from the bottom to such an extent that a man, in the event of a short circuit between the winding and the frame, might get a shock while standing on the floor of the mine. In dry places this usually is not a hazard, but it may be a source of danger in a wet mine.

A greater hazard can exist when the machine is loaded on a truck, as at this time it may be on a track that is insulated from the earth. Even there the value of a ground wire is questionable, as it would be better to bond the rails. With machines that cut coal while resting on a track and with loading machines and conveyors a condition arises similar to that when a short-wall mining machine rests on a truck. This also can be met by bonding the rails where necessary. Equipment fitted with caterpillar trucks is in sufficiently close contact with the earth to be considered properly grounded.

A somewhat different problem is involved in the use of portable electric drills, and it is considered advisable to use a cable having a separate conductor for grounding. Grounding is deemed necessary by the fact that the drill may not be in contact with the earth and may be actually in the hands of the operator.

SURGES MAKE ALTERNATING CURRENT DANGEROUS

Up to this time the voltage or character of current has not been mentioned inasmuch as all power circuits present a certain hazard due to their ability to produce a shock that may result fatally. The hazard varies with respect to the voltage as well as with the character of current. Of ordinary underground current direct current of 250 volts probably presents the least hazard and 440-volt alternating current the greatest. The hazard of shocks from direct current at a given voltage is less than from alternating current having the same voltage reading. The alternating-current voltage shown on a voltmeter is the mean voltage and not the maximum and that must be remembered whenever shocks are being considered.

Alternating current has the added danger that the voltage may be materially increased by surges on the transmission line, or contact with a high-potential circuit due to an accident at the transformer or switching equipment.

It will probably be in the interest of safety to have all underground alternating-current circuits used for operating three-phase mining machines and similar equipment connected "Y" with the middle point grounded. The cases of all transformers connected to circuits supplying power for the operation of underground equipment should be properly grounded with a wire independent of that used for the grounding of lightning arresters.

The lack of proper grounding of electrical equipment has been responsible in the past for a number of fatalities in the coal-mining industry and still continues to be an important hazard, but with our increasing knowledge of the value of grounding and the exercise of reasonable care, it is being materially reduced.

THE LONGWALL SYSTEM of coal mining is being extended in the Sydney Mines district, N. S., having been found suitable to conditions in the collieries. It is expected to be particularly advantageous in the operation of the Princess mine, where, owing to its adoption, no further development will be necessary for ten years. It is asserted that labor costs will be reduced and the output increased.

West Virginia Mining Institute Discusses Safety Measures at Elkins and Views Conveyor Mine

Classify Your Accidents as You Would Your Operating Costs—
Interchangeable Copper Fuses in a Locked Fuse Box Favored—Socket
Box on Rib at Each Room and Repair of Cables Outside Mine Advocated

STATISTICS were given and analyzed at what is said to be the best meeting ever held by the West Virginia Coal Mining Institute, at Elkins, June 17 and 18, which show that in Pennsylvania second mining is more hazardous than first mining but that the relative positions of these two operations in the scale of danger and safety can be exchanged by concentration methods of mining. It was made evident also that much remains to be decided as to the best methods of grounding electrical mining machinery. Blowout fuses, what they should be and where they should be installed to protect machines and the men who operate them, also were discussed. J. W. Paul, chief of the coal mining investigations conducted by the Bureau of Mines, remarked, "Wherever the engineering profession devotes itself to accident prevention, it accomplishes something." The problem rightly should be regarded as the engineer's.

Though Elkins is inaccessible from many parts of the state all regions were represented. Several men from Logan County were en route for 36 hours to join with more than 100 men who attended the meeting. The afternoon of the first day was devoted to papers and discussions, the evening to entertainment, and the following morning to an inspection trip.

FOREPOLING ROOF MAY DO MORE THAN CAUTION

Newell G. Alford, consulting mining engineer of Pittsburgh, in his paper on "Engineering and Accident Prevention," conveyed the need for better engineering methods and more extensive use of labor-saving machinery. His theory is that machines and mining methods that facilitate their use will allow the coal to be extracted before the roof (which is responsible for most accidents) begins to work and come down. He let tables and charts do his talking. His paper will appear in next week's issue.

There was little discussion of Mr. Alford's paper because the majority of the coal companies represented do not so classify the accidents that occur in their mines that such information can be properly correlated. Nevertheless he impressed the operators with the advantages that might be derived by such systematic classification in measuring the efficiency of methods. The moral of his paper is that good engineering, not only saves operating costs but lowers accident rates.

According to Dr. Rutledge, one company mined 2,225,000 tons of coal in 47 months without a single fatality. This record for safety came to an end by a death that was due to the carelessness of the man who was the victim of the accident. Someone in the audience attributed this record to education, particularly by extension courses promoted by the state. Robert Lambie defended West Virginia by saying that the Gay Coal & Coke Co., Logan County, has a better record.

An example of how good engineering makes mining

comparatively safe even under hazardous conditions was given by Dr. Rutledge, referring to the methods now being used to recover pillar, roof and bottom coal from old mines in the Big Vein seam on Georges Creek. He said that forepoling and careful timbering has made it possible to tunnel through old workings and reach this valuable coal.

A telegram from E. C. Jones, Glen White, W. Va., who was scheduled to read a paper on "Stray Currents," informed the institute that sickness in his family deterred him from attending the meeting. Charles M. Means, consulting engineer, of Pittsburgh, read a paper on "Grounding of Electrical Machinery," which appears in this issue.

ALTERNATING CURRENTS NOT RATED BY MAXIMA

Dr. Rutledge opened the discussion of Mr. Means' paper by telling of some of his early observations of alternating-current installations. He said for a number of years this kind of current gave much trouble. The legislators and the labor interests wanted to prohibit its use underground. Mine inspectors and electrical engineers disagreed as to the way in which alternating current should be handled.

In answer to a question relative to voltages of alternating-current underground circuits Mr. Means warned against the use of 440 volts. A voltmeter reading registers only the mean voltage, whereas the maximum voltage may be 800. William Jarvis mentioned the English method of grounding in which a third wire is carried from a junction box to the generator in case of a two-wire direct-current system, and a fourth wire is similarly carried where alternating current is used. Dr. Rutledge asked what precautions might be taken in a scheme of that kind to prevent incorrect plugging of the terminals. Mr. Jarvis suggested that a color for each wire or some mechanical scheme would make identification easy.

WAY TO AVOID INSERTION OF WIRE IN FUSE

The discussion turned to cable and cutting-machine fuses. Dr. Rutledge sees a means of eliminating the dangers of copper fuses by the use of a locked fuse box. A piece of equipment of this kind is now on the market. It is so arranged that each of six fuses will burn out successively before a replacement is necessary. Mr. Lambie believes in having a socket on the rib tapped from the trolley wire to keep men away from the wire in plugging-in. He recommends the use of a fuse in the cable in addition to one on the machine to which it conducts power. Mr. Kingsland of the Consolidation Coal Co. said that he has a padlocked fuse box on one of his storage-battery locomotives. It contains three fuses; when all of these are blown they are replaced by the mine electrician who is the sole possessor of a key for the lock. This same equipment could be used on cutting machines.

In Alberta, power cables are often repaired on the outside of the mine, remarked Dr. Rutledge. This practice insures a thorough job. He also mentioned the fact that insulated cable nips with enclosed fuses are being introduced in a few mines.

In response to President J. W. Reed, Fairmont, Mr. Means stated that shocks from an ungrounded alternating-current circuit would be prevented, of course, if all three wires were thoroughly insulated. But leakage almost invariably occurs giving the man who furnishes the path between the ground and the wire with which he comes in contact the full benefit of the difference of potential between them.

Asked whether transformers should be placed inside or outside mines Mr. Means replied that virtually there is no difference between the two locations except that the inside location presents a fire hazard because the oil is likely to ignite. Fireproof stations are necessary therefore. Mr. Chapman asked if a person touching a 220-volt alternating-current line would get the maximum of mean voltage. Mr. Means replied that he would get the maximum voltage which is considerably greater than the mean potential of 220 volts.

Mr. Barrett is of the opinion that after all pains are taken to make the grounding of alternating-current equipment as thorough as possible, an added precaution should be taken to insulate it, as no ground is reliable.

In the second half of the program, three papers were presented. The first of these, on "Abuse of Explosives," was delivered by W. J. German, of Huntington, W. Va.; the second, on "Explosion Hazards Investigation in Coal Mines," by J. W. Paul, Pittsburgh, Pa.; and the third, on "Rock Dusting of Coal Mines; Efficacy, Methods and Cost," by Edward Steidle, Pittsburgh Pa. A general discussion followed the reading of these papers, led by John T. Ryan.

In discussing Mr. German's paper on explosives, R. D. Lambie remarked that the mine law of West Virginia requires explosives to be carried in fiber containers, Mr. German declaring that in most cases the men stuffed the explosives in their pockets. In a discussion as to whether it was a desirable practice to contract out the drilling, tamping and shooting of coal to be done at night and without supervision Mr. German said that some shotfirers unless carefully watched, especially at night, are liable to shoot two holes simultaneously. Mr. German favors air-spacing only where the thickness of the coal is less than the depth of the cut.

INFLAMMABILITY DEPENDS ON FUEL RATES

In his paper, which dealt entirely with the hazards of coal dust, Mr. Paul gave an empirical formula deduced from laboratory tests for determining the degree of inflammability of coal dust. It is $R = V \div (V + FC)$, in which R is the volatile ratio, V the volatile matter and FC the fixed carbon. This formula aids in establishing the minimum quantity of incombustible matter needed by any given mine dust to render it harmless.

In response to Mr. Alfred, Mr. Paul said that when the Bureau declared that 5 oz. of coal dust per lineal foot of entry would propagate an explosion it based that figure on dust from the Pittsburgh seam, which had a volatile percentage of about 36 and on an entry measuring 6x10 ft.

John T. Ryan said that with only a few months of experience the methods being used in the United States for rock dusting are superior to those used after years

of experimentation by Great Britain. This country should not follow European methods because conditions here are vastly different. In England, for instance, electric haulage is not used, labor costs are low and consequently mechanical means of distributing rock dust are not employed. The cost of rock dusting per ton of coal mined should be no higher in this country than in England for it will be done by machinery, whereas hand methods are often used in Britain.

Everett Drennen questioned whether all layers of rock and coal dust on roof, rib and floor should be considered in determining the percentage of incombustible matter, seeing that the two dusts might be stratified. It is certain, however, that when the waves in advance of the flame of an explosion dislodge and stir up the dust the stratification will be destroyed. Mr. Reed questioned the effectiveness of rock dust in a wet mine but Mr. Ryan explained that a mixture of wet rock and coal dusts is safe; when one dries out so does the other, for which reason a safe condition prevails, wet or dry.

Mr. Haas questioned whether the pulverizing plant should have as large a capacity as suggested by Edward Steidle, namely 1,000 lb. of rock dust per hour. Mr. Ryan replied that the crusher obtainable produces 1,000 lb. per hr., and furthermore that it is planned to have the plant operated by company men having other duties to perform.

The Institute adjourned at 6 p.m. It met again that evening at an informal dinner at the Hotel Tygart.

"V" SYSTEM NOW EXTENDS UNDER HEAVIER COVER

On the morning of the second day a party of seventy men drove in automobiles to the Norton mine of the West Virginia Coal & Coke Co., where mining by the "V" system with conveyors was observed. Better results are being obtained with this system as time goes on. When it was described in the Feb. 7 issue of *Coal Age*, coal was being mined in a section near the outcrop and under light cover. Two batteries are now working in as many sections under heavier cover. From 1,600 to 1,800 tons of coal are produced daily from these two sections. Room mining has been stopped; The Norton mine, therefore is a mechanical mine. A precaution has been taken recently to settle the dust raised where the coal discharges from one conveyor to another. Small water lines are tapped from the drainage pipes and conducted to these points where the water is sprayed on the coal through a stationary nozzle.

The action of the roof apparently can be better controlled under the heavier cover. Falls of roof have less tendency to encroach on the protruding points, which, to all appearances are being kept open after each cut with a fair degree of regularity. Stumps lost in the goaf as far as could be seen are neither long nor wide, indicating a recovery higher than that obtained near the outcrop.

The mine officials explained that some minor changes will be made in the layout of the system. Ten faces instead of eight faces will be worked in a battery. The distance between galleries, also, will be increased from 80 to 100 ft., so that, the faces, still maintained at an angle of 45 deg., will be increased in length to 100 ft. The face conveyors, accordingly, will be made 87 or 93 ft. in length depending upon the results obtained; and five men instead of four will put coal on the conveyor. Two batteries of this size will produce about 2,500 tons of coal per day.

Should Buffalo's Gas Be Made at the Coal Mines?

By So Doing One and One Quarter Cents Would Be
Saved per Thousand Cubic Feet, Provided There Were
No Leakage—Outlay of Two Million Dollars Required

SEARCHING for cheaper fuel to replace the natural gas which is coming in decreasing quantity to Buffalo, N. Y., and gas manufactured by obsolete equipment by a company in financial difficulties that city established a co-operative agreement with the U. S. Bureau of Mines for the purpose of solving its problem. A report entitled "A Fuel Problem for the City of Buffalo, N. Y." has been made by G. S. Brewer, assistant fuel engineer, U. S. Bureau of Mines and B. J. Hatmaker, consulting geologist, department of public works, Buffalo, N. Y. which is extremely valuable and interesting. Among other matters the authors discuss the possibility of making gas at the coal mines and piping it to Buffalo. The following is a quotation from that report:

Some of the gas journals of late have given much space to the possibility of producing gas from coal at the mine and transmitting it through a long pipe at high pressure to the point of consumption.

In order to indicate whether or not such a plan would be feasible for Buffalo, the estimates in Table I have been made:

**Table I—Estimated Cost of Transmitting Gas by Pipe
Line from Coal Mine to Buffalo**

(Compared to Shipping the Coal by Rail to Buffalo and Making Gas Locally.)

Cost of pipe line, capacity 1,000,000 cubic feet per hour (125 miles long @ \$1,000 per mile per inch of diameter of pipe using 12-in. pipe).....	\$1,500,000.00
Cost of compressor station.....	\$437,000.00
Interest and depreciation on pipe line at 10 per cent.....	\$150,000.00
Interest and depreciation on compressor station at 12 per cent.....	\$52,500.00
Operating cost of compressor station per year.....	\$49,200.00
Total cost of transmitting gas pumped per year based on present estimated requirement of 5,363,000 M. cu.ft.	\$251,700.00
Surplus coke produced at the mine.....	7,100 tons
Freight on coke assumed shipped to Buffalo for domestic use at \$2.60 per ton.....	\$18,500.00
Total cost transmitting gas and shipping surplus coke per year. \$251,700 plus \$18,500.....	\$270,200.00
Cost of transmitting 1,000 cu.ft. of gas and accompanying coke.....	0.0504
Cost of shipping coal to carbonizing plant in Buffalo per 1,000 cu.ft. of gas produced from it.....	0.0627

(1) Compiled from Weymouth, Thomas R., Transactions American Society of Mechanical Engineers, Vol. 34, 1912, page 133; and from minutes of hearings of the Buffalo Gas Case of 1918 before the Public Service Commission of New York.
Gain due to production of gas at the mine per 1,000 cu.ft. .00123
This does not take into account any gas loss due to leakage in the pipe line.

The cost of the pipe line was based upon figures given by Mr. Weymouth and from the cost of laying a pipe line from Cattaraugus Creek to Buffalo, a distance of 34 miles. The figures quoted are \$900 per mile per inch of pipe diameter, but because the cost of constructing a pipe line over the hills of Pennsylvania to the coal mine would probably be more than estimated for building it across the more level section of New York State, in this report \$1,000 per mile per inch diameter of pipe is assumed. Interest and depreciation charges are given at a rate of 10 per cent which is said by Mr. Weymouth to be a safe assumption.

The quantity of gas required per day was estimated throughout the year at 266 cu.ft., daily per meter with approximately 105,000 meters installed. A little allowance was made also for increase in demand, bringing the total estimated quantity up to 24 million cubic feet per day. By empirical formula, the horsepower of the

compressor was computed to be 4,370. This horsepower is sufficient to pump a maximum of twenty-four million cubic feet of gas per day.

Mr. Weymouth's figure of \$100 per installed horsepower as the cost of compressor stations was used making a total cost for the 4,370 hp. station \$437,000. Again using Mr. Weymouth's figures, interest and depreciation charges at 12 per cent = \$52,500 for the compressor station. Operating expenses at \$15 per horsepower per year assuming 75 per cent of the total capacity as the yearly average actually used mount to \$49,200. Therefore, the total yearly cost of operating a pipe line 12 in. diameter, 125 miles long using an initial pressure of 370 lb. per square inch absolute, a terminal pressure of 50 lb. per square inch absolute, pumping a maximum of twenty-four million cubic feet of gas per day and a total of 5,363,000 M. cubic feet per year, the specific gravity of which is assumed to be 0.60, figures to be \$251,700.

PIPE GAS FOR FIVE CENTS PER THOUSAND FEET

The cost of transmitting gas through this pipe line per M. cubic feet will therefore be,

$$\frac{251,700}{5,363,000} = \$0.0469 \text{ per M. cu.ft.}$$

In the coldest weather it is assumed that large quantities of water gas will be made and mixed with the coal gas. In order that the gravity of the gas may not change too greatly, some water gas should be mixed with the coal gas even during the period of minimum demand for gas.

The total quantity of blue water gas required per year is estimated at 3,863,000 M. cu.ft. The coke required to make this allowing 39 lb. of coke per 1,000 cu.ft. blue water gas is 75,400 tons. Allowing 300 lb. of coke for bench or oven fuel per ton of coal carbonized, 150,000 tons of coal would require 22,500 tons of coke. Subtracting these quantities from a total of 105,000 tons of coke made per year, 7,100 tons remain to be sold, either in Buffalo or elsewhere. In this computation we shall assume that both the mixed gas and the excess coke are used in Buffalo. The freight on 7,100 tons of coke from the mine to Buffalo, assumed at \$2.60 per ton is \$18,500. The cost of transmitting gas and shipping coke to Buffalo, therefore totals to \$270,200 or \$0.0504 per M. cu.ft. of gas produced.

On the other hand, the freight on 150,000 tons of coal at \$2.24 per ton from Pittsburgh amounts to \$336,000 or \$0.0627 per M. cu.ft. of gas made, a gain of \$0.0123 per M. cu.ft. for gas made at the mine, assuming no pipe line leakage.

From a study of these figures it is apparent that the saving from the production of gas made at the mine over the production of gas made locally will be slight. If there is any appreciable leakage in the pipe line, and usually it is considerable, the gas that finally reaches Buffalo would have to be sold at a figure which would be substantially higher than that for gas manufactured locally.

News Of the Industry

Reorganization of Statistical Bureaus Beset by Thorny Path

Transfer of Compilation of Mineral Data Opposed by Census Department as Well as Geological Survey—Industry Interested Pending Clarification of Legality of Issuance of Association Data

BY PAUL WOOTON
Washington Correspondent of *Coal Age*

Correspondence reaching Washington indicates a misapprehension on the part of the mineral industries as to the status of the reorganization legislation. The proposed plan which would transfer the statistics of mineral production from the U. S. Geological Survey to an enlarged Bureau of the Census, to be known as the Bureau of Statistics, is far from being an accomplished fact. The whole question of reorganizing the government departments is so intricate and controverted that it is entirely possible that no legislation along the lines indicated in the Mapes bill will pass. Before any such plan is made effective it is safe to predict that it will have been amended in a great many particulars. The prospects are that the proposal with regard to the mineral statistics will not be approved, as it is opposed in the Bureau of the Census as well as in the Geological Survey.

Industry Depends on Survey Data

It is evident that the anxiety of the mineral industries concerned with statistical services is due to the reliance that must be placed on these figures as long as the status of trade associations remains in doubt. Many of these organizations have abandoned a portion of their statistical program pending the clarification of their legality. For that reason such statistics as are issued by the government assume an increased importance.

Various of these inquiries apparently were prompted by an article in this correspondence which appeared on page 885 of the June 12 issue of *Coal Age*. It was not the intention in that article to give the impression that any such change is imminent. That article was prompted simply by the fact that the joint committee on reorganization had submitted its report to Congress. Since four years have been required to initiate the legislation, an indication is given of the difficulties likely to surround its further progress. Likewise in that article there was no intention of reflecting on the general efficiency of the Bureau of the Census. In the effort to reflect the widely held opinion that such statistics as those of mineral resources should be compiled by the specialists who have to use them and

who are in a position to interpret them, reference was made to the difficulties surrounding the compilation of such figures by a central statistical agency.

The Bureau of the Census and the Geological Survey are typical of two distinct methods of approaching the statistical task. The Census Bureau deals with a wide range of subjects, in addition to the task of enumerating the population. In the accomplishment of such work its performance is remarkable. One of the striking accomplishments of the federal government is the effective way in which the Census organization, within a very few days, makes the count of the nation's people. The Bureau of the Census is the largest agency of its kind in the world and was the first to develop machine methods of tabulating statistical facts. Much of the tabulating and assorting machinery in operation in that Bureau was invented and developed by Census employees. In no other statistical organization in the world have costs been reduced to such a low level. As Secretary Hoover puts it, the Bureau dredges up great buckets of facts.

Statistics a Means to Larger End

The Geological Survey, on the other hand, produces a type of statistics in which the statistical results are regarded not as an end in themselves but as a means to a larger end—an understanding of the industry. The secret of their merit is the vital contact between the collection of the data and their application to the industry.

Industry is not interested in the department or in the bureau which handles its statistics. It is generally recognized by industry, however, that the work should be done by those who make it their permanent job to study some particular specialty. Thus the coal statistics are handled by coal specialists, the oil figures by petroleum specialists, rare metals figures by men who devote their entire time to that specialty, and so on through the list.

It has been the employment of this principle of specialization on commodities that has given such strength to the Bureau of Foreign and Domestic Commerce of the Department of Commerce. In that Bureau are specialists who deal

Hocking Miners Want Scale That Will Get Work

Forty-eight delegates, representing approximately 12,000 union miners in the Hocking Valley field, recently unanimously adopted a resolution inviting mine owners and operators in this section to meet in joint conference to discuss amendments to the wage scale and working conditions with a view to cheapening the cost of mining. It is understood that operators have signified their intention of accepting the invitation and the joint session probably will be held early in July. Mines in this section have been idle for months, owing to inability to compete with other mining fields.

with single commodities who can use and interpret statistics to the utmost advantage. The Geological Survey organization carries that type of co-operation one step further. It places the collection of commodity statistics under the supervision of the commodity specialists and weaves the quantitative results into one complete picture along with qualitative results of observation and intimate acquaintance with the field.

Lewis Again Warns Against Wage Reductions

John L. Lewis, president of the United Mine Workers, reiterated at union headquarters in Indianapolis, June 19, that the international organization, which suspended the autonomy of District No. 17, West Virginia, and assumed charge of the union affairs there June 14, will not submit to any reduction in miners' wages. The declaration was made in an official circular announcing the change in the West Virginia district.

"Strikes now in effect will be prosecuted until settlements are reached on the basis of the Jacksonville agreement," the official announcement reads. "There will be no modification of existing wage agreements now or later."

It was stated that operators in a few other districts have refused to sign contracts based on the Jacksonville agreement, and the union has declined to concede a wage reduction demanded by the operators, thereby causing strikes in places other than West Virginia. The declaration of policy regarding West Virginia in the official circular was said at union headquarters to be regarded as notice that no wage reductions will be permitted anywhere.

Strike in German Coal Mines Proves Unprofitable to Workers

Conceded 15 per Cent Increase from the First, Miners Obtain 20 per Cent Advance and Recognition in Principle of Seven-Hour Day—
Will Work Eight Hours Daily for the Present

Berlin, June 6.—After a strike lasting nearly four weeks and causing enormous losses, the Ruhr coal miners have resumed work, on condition that they get a 20-per cent increase of wages from June 1 and that, while the seven-hour day is recognized in principle for underground workers, eight hours will be worked for the present. As a 15-per cent wage increase was conceded from the first, the strike proved highly unprofitable. The wages lost by 450,000 strikers total 58,800,000 gold marks; and the production loss of 7,194,000 metric tons would have had a value of 149,850,000 gold marks, or nearly seven times as much as in the last important strike in 1912.

Production has now returned to about the post-war normal. Owing to the Ruhr troubles 1923 was not a normal year; but it is given here together with 1922 and 1913 for purposes of comparison, the figures (in thousands of metric tons) referring to the whole of Germany:

	Output	Imports	Exports	Consumption
1923..	97,607	25,000	2,000	120,676
1922..	175,500	15,427	23,577	167,550
1913..	219,186	16,200	44,043	189,403

Owing to the large imports and meager exports in 1923, the quantity available for home consumption was not so dangerously curtailed as would appear from the production figures taken alone. The home production in the first four months of 1924 was on the whole satisfactory, being as follows in thousands of metric tons:

	January	February	March	April
Coal.....	8,787	9,726	10,825	10,429
Lignite (b r o w n coal).....	9,553	8,327	10,931	10,247
Coke.....	1,474	1,742	2,102	2,219

In the first quarter of 1924 coal output exceeded that of the corresponding quarter of 1923 by 3,750,000 tons, whereas output of lignite (which was forced in 1923 owing to shortage of Ruhr supplies) was 7,320,000 tons less. The coal figures do not include the output of three mines which are worked directly by the French Régie. Imports of coal this year have fallen to about half those of 1923, as shown in the subjoined table in thousands of metric tons:

1924	Coal	Lignite	Coke
January.....	1,087	117	81
February.....	1,232	138	54
March.....	980	169	25

Against this, exports of coal and lignite, though not of coke, have fallen; and Germany's foreign payment balance is still heavily burdened by the coal import surplus, though not so heavily as last year. Exports were as follows in thousands of metric tons:

1924	Coal	Lignite	Coke
January.....	97	7	25
February.....	69	12	36
March.....	63	17	40

In spite of pessimism in business circles there has been no serious shortage of coal for industry since the war, except in 1923 and during the May (1924) strike. The reasons for this are the greatly increased output and direct use of lignite, increasing electrical generation with lignite, more economical methods of firing, increased imports and greatly reduced domestic consumption. The recent curtailment, however, was not due to a shortage. The rationing of fuel for domestic use ceased

H. K. Cortright

President of the American Wholesale Coal Association, elected to succeed C. L. Dering at the recent convention of the association at White Sulphur Springs, W. Va.

two years ago. The chief cause was the temporary inability of large classes to pay for fuel, which was burdened formerly with a 40 per cent tax, since abolished. High prices led to a general suspension of central heating in city houses. No figures for all Germany are available; but in October, 1923, the consumption of lignite briquets for domestic heating in Berlin fell to 41,165 tons against 160,690 tons in October, 1922. Owing to the rentenmark currency reform, which has largely increased the average citizen's buying power, central heating is now being resumed everywhere.

The German coal trade is in a confused condition. The abolition of state control and rationing has resulted in the disappearance of binding prices; thousands of small dealers have sprung up, who ignore the syndicates' attempts to keep prices steady. When short of money, as most German business men are today owing to the credit crisis, these new dealers sacrifice their stocks of coal at prices below production cost and willingly bear the loss rather than apply for bank credit, which costs 60 to 80 per cent per annum on

Every Stockholder A Coal Seller

Foreseeing a period in which retail coal selling will not be lucrative, the Consumers Co., of Chicago, is entering upon a most intensive sales effort. Fred W. Upham, nationally prominent Republican politician and president of the company, has sent out a letter to all his stockholders telling them the company has consistently paid a 7 per cent dividend every six months and hopes to continue it but that if there is to be any profit out of the business in this year of narrow margins the company must sell at least 25 per cent more coal. In order to do this every employee is under orders to consider himself a salesman and bring in business. The same appeal is made to every stockholder.

first-class security. At the Coal Dealers' annual Congress, held this week, the representatives of the big dealers appealed for united action to suppress the so-called "savage" (outside) dealers.

Germany's coal future is very doubtful, depending as it does upon restoration of her economic control over the Ruhr. Although such restoration is one of the main conditions of the Dawes reparations recommendations, not much confidence is felt. Meantime Germany's control over coal fields is so small that she has declined from first position to fourth among European coal powers. In 1913 her underground coal reserves were estimated at 424 billion tons, or 52.1 per cent of the reserves of all Europe; Great Britain coming next with 189 billion tons, or 23.2 per cent; European Russia next with 50 billion tons, or 7.4 per cent. Through the Versailles Treaty Germany lost the Lorraine fields with 800 million tons, and the Saar with 12,200 million tons; and through the Geneva decision of 1922 she lost the greater part of the East Silesian coal fields, estimated at 176 billion tons. In all her loss was 189 billion tons.

Allowing for Poland's gains and European Russia's losses, the position today is as follows: Germany, 235 billion tons, or 28.9 per cent of all Europe's supplies; Poland, 208 billion tons, 25.6 per cent; Great Britain, 189 billion tons, or 23.2 per cent; Russia, 47 billion tons, or 7 per cent. Germany, however, has since lost control over the greater part of the above share as a result of French occupation of the Ruhr and Left Rhine fields. She controls today (including lignite) only about 64 billion tons, or 7.9 per cent of all Europe's supplies, being behind Poland, whose supplies are given above; behind France, which now controls 202 billion tons, or 24.8 per cent, and behind England. Her directly owned and controlled fields contain the following estimated reserves in metric tons:

Lower Silesia.....	3,000,000,000
Upper Silesia.....	35,000,000,000
Westphalia.....	19,000,000,000
Saxony.....	1,900,000,000

In addition are 6 billion tons of lignite in unoccupied territory, mainly in central Germany.

St. Bernard Miners Take 20 per Cent Wage Cut

Some of the union employees of the St. Bernard Mining Co., in western Kentucky, have agreed to go back to work at a wage scale 20 per cent below the standard union rate. The company made the deal with certain of its men last week and expects to open four of its mines some time this week. It is still uncertain, however, as to how many will go to work. The agreement puts the St. Bernard properties on an open-shop basis with a wage scale paralleling that of the West Kentucky Coal Co., whose mines have been open-shop for a long time and whose men were reduced to the 1917 scale about two months ago. The St. Bernard mines were purchased last spring by the North American Co., which owns and operates the West Kentucky Coal Co.

Although it was announced at Earlington, headquarters of the St. Bernard company, that about 1,000 men had agreed to resume work, Lonnie Jackson, of Central City, president of the western Kentucky district of the United Mine Workers, hooted at the idea, declaring late last week that only a handful of St. Bernard men had agreed to the wage cut and that not enough men would report to man one mine, not to mention the four the company proposes operating. He did not openly issue any threats concerning what the union will try to do to stop this long-expected spread of non-unionism in western Kentucky, but he did say that the loyalty of his district is unquestioned and that there is no danger of a break in the ranks of the men who have been on strike since April.

It is generally known that President Jackson has frankly admitted that the union miners in western Kentucky ought to take a 20 per cent cut. He was rebuffed severely, however, when he and his district board went to Indianapolis, Ind., and tried to get International President John L. Lewis to sanction it. The delegation was sent back home with orders to fight it out. That is what Jackson is still trying to do.

Ever since negotiations between operators and miners were broken off in April, shutting down practically all of the field except the several mines of the open-shop West Kentucky Coal Co., it has been freely prophesied that the

Shake-Up in Bureau Of Mines

A number of changes have been made in the technical division and offices of the U. S. Bureau of Mines as the result of an order approved by the Secretary of the Interior, Dr. Hubert Work. The division of metallurgy has been placed under the direction of the chief metallurgist, who will have administrative charge of the field studies now being conducted at Miami, Okla.; Moscow, Idaho; the Massachusetts Institute of Technology and at the Bureau of Standards, together with the co-operative studies on oxygen enrichment of air blasts.

George S. Rice, chief mining engineer, has been relieved of most of his administrative duties and will serve as adviser to the director and assistant director on mining matters, with such special duties as may be assigned to him from time to time. For the present he will be in entire charge of matters relating to co-operation with the British Government in studies of safety in mines. The division of war mineral supplies has been abolished and its duties, records and personnel have been transferred to the division of mine research.

union would have to take a wage cut or quit business. The St. Bernard mines, normally employing 2,300 men, were at once the largest group in the striking field and the weakest spot in the union's front. Relations between that company and its men have been cordial and when the company recently issued a sort of ultimatum to the men through Frank D. Rash, operating head under the direction of C. F. Richardson, president of the West Kentucky Coal Co., showing the men how economically impossible it is for the mines to be opened at the union scale, the back of the strike gave evidence of breaking. Some of the men asked on what basis they could go to work. The company told them to determine that among themselves and come back with a proposition. The 20 per cent cut was the result.

The rest of the field remains on strike and watching St. Bernard activities with great interest.

Discuss Steps to Prevent Mine Accidents

Important steps to prevent mine disasters were discussed at a meeting at Elkins, W. Va., June 18, attended by mine owners, mine officials and miners, the first of a series called by Robert M. Lambie, chief of the West Virginia Department of Mines. Approximately 100 employers and employees were present at the meeting. Mr. Lambie opened the discussion by pointing out that six mine disasters, exacting a toll of 398 lives, had occurred this year. At least 90 per cent of explosions could be eliminated, he said, through proper precautions, pointing out changes that should be made in thirty-six sections of the mining law of the state. Plans and suggestions for changes and revision of the law were then submitted for open discussion.

Important among the changes submitted by the mine chief and which met the approval of those attending the meeting was the use of approved electric mining lamps in all mines. The law at present enforces this practice in mines known to contain dangerous quantities of gas, but it is urged that the electric lamp be used in all mines. In this manner, Mr. Lambie declares, explosion hazards from gas ignition can be reduced 80 per cent.

It was pointed out that the present laws prevent the department from enforcing restrictions and safety measures in cases where oil and gas companies sink drills through coal veins. Through the use of permissible explosives in all mines at least 60 per cent of explosions due to fuse ignition can be eliminated. The present law covers only certain mines, as in the case of miners' lamps.

Among other important measures discussed and favored for incorporation in the state mining laws was the use only of certified shotfirers, who should be required to pass a state examination before entering upon their work, improved systems of ventilation, especially in the cases of new mines; rock dusting and rock-dust barriers.

The salient points which those present at the meeting discussed and which received the endorsement of all were ample ventilation, proper inspection by firebosses before work starts, adequate supervision, use of approved electric lamps, of which more than 8,000 are now in use in the state, permissible explosives only, certified shotfirers, permissible machinery in gas-liberating mines.

After the discussion had been concluded a committee of four was appointed to call further meetings for drawing up the best measures favorable to local miners and officials. At each of the other six meetings like committees will be appointed and they will later meet at Charleston with a commission to be appointed by Governor Morgan.

When the recommendations evolved as a result of all the meetings are finally whipped into shape for presentation to the Legislature, West Virginia is expected to have the most thorough and modern mining laws in the United States.

Coal Haulage in India at Five Cents a Ton

The ordinary method of moving coal from the face out of slope mines in India is by woman-power, 12-ton coal tubs familiar in various parts of the British Empire. S. W. Farnham says the Indian miner, who is a farmer part of the time, always insists upon taking his women into the mine with him, whether they work or not, in order to keep them in the straight and narrow path.

World's Production of Coal in 1923, 3,337,000,000 Tons, Largest Since 1917

World's production of coal in 1923, according to the U. S. Geological Survey, was the largest in any year since 1917 and fell somewhat short of that in 1913, the last year preceding the World War. The total output is estimated at 1,337,000,000 metric tons, as compared with 1,342,000,000 tons in 1913.

The failure of production to reach the pre-war level is the more significant when it is remembered that the world's consumption formerly increased by leaps and bounds. The average rate of increase in the 20-year period preced-

ing August, 1914, was 38,000,000 tons a year. In part the present low production is due to the economic disorganization wrought by the war, particularly in Germany, France and England. In part it is due to more efficient use of fuel, stimulated by the high prices of recent years. A factor of still greater influence is the extraordinary increase in the supply of petroleum. The world's production of crude oil in 1923 exceeded that of 1913 by 625,000,000 barrels, equivalent to approximately 170,000,000 tons of coal.

The term "coal" as used by the Geo-

Railroads Buy 28 per Cent Of Soft-Coal Output

Class 1 railroads of the United States in 1923 purchased directly from the industries of the country fuel, materials and supplies to the value of \$1,783,703,000, R. H. Aishton, president of the American Railway Association told the fifth annual convention of Railway Purchasing Agents in session at Atlantic City, June 16.

Of the total amount, \$617,800,000 was expended for fuel, Mr. Aishton said, or about one-third of the total expenditure. More than 28 per cent of the total amount of bituminous coal produced in the United States in 1923 was purchased by the railroads at a cost of \$519,007,000, while they also purchased 5.2 per cent of the total anthracite production at a cost of \$18,195,000. Fuel oil amounting to \$75,867,000 and consisting of about one-fifth of the total production and consumption in the United States also was purchased by the railroads, while \$4,731,000 was expended for other kinds of fuel such as coke and gasoline. These amounts represent expenditures on account of fuel for all purposes, whether for locomotives, shops or the heating of buildings.

(a) Estimate included in total. (b) Exclusive of the State of Falcon (about 8,000 tons), for which estimate is included in the total. (c) Includes entire output of Upper Silesia for January-May; for June-December only that part of Upper Silesia allocated to Germany. (d) Includes for June-December that part of Upper Silesia awarded to Poland. (e) Exclusive of lignite from Japan (annual production of about 200,000 tons) for which estimate included in the total. (f) Russia in Asia included with Russia in Europe. (g) Estimate based on 11 months' production. (h) Estimated on incomplete data.

logical Survey includes lignite, and the production for the world is simply the total of quantities reported, no attempt being made to reduce the statistics for inferior coals to an equivalent tonnage of coals of higher rank. Where possible, however, coal and lignite are shown separately.

In comparison with 1922, the year shows an increase of 114,000,000 tons, in which the principal element was a recovery of 149,000,000 tons in the production of the United States. All of the large producing countries, however, except Germany, Japan and British India, reported an increase, and the output of France was but 3,000,000 tons below the pre-war level. The outstanding feature of the year was the tremendous decline in the production of Germany, associated with the economic disorders that attended the occupation of the Ruhr. The figures from Germany are official.

World Production of Coal, 1910-1923

(In metric tons of 2,204.6 lb.)

Year	Production, In Part Estimated	Per Cent Produced by United States
1910	1,160,000,000	39.2
1911	1,189,000,000	37.9
1912	1,249,000,000	38.8
1913	1,342,000,000	38.6
1914	1,207,000,000	38.7
1915	1,193,000,000 (a)	40.5
1916	1,291,000,000 (a)	41.5
1917	1,356,000,000 (a)	43.6
1918	1,333,000,000 (a)	46.3
1919	1,173,000,000	42.8
1920	1,319,000,000	45.3
1921	1,134,000,000	40.4
1922	1,223,000,000	35.2
1923	1,337,000,000	43.5

(a) Revised from earlier reports to conform with more accurate information on certain of the warring countries.

Midwest Dealers Still Fight Snowbirding

Charges against it and investigations into the affairs of its commissioner by the Federal Trade Commission have not dampened the ardor of the Midwest Retail Coal Association in its battle against "snowbirding." At its fourth annual convention, in St. Louis, Mo., last week, the association decided to continue its active existence and to back Commissioner E. J. Wallace in the work he has been doing. Mr. Wallace lambasted "government by commission" in his characteristic vitriolic language.

The association adopted resolutions demanding that Congress find out why the Federal Trade Commission fails to protect legitimate business against the doubtful advertising and questionable methods of coal "snowbirds," demanding that the commission compel concerns with no coal mines to cease using the word "mining" in their corporate names, asking the Interstate Commerce Commission to extend the unloading period on coal before demurrage begins, and calling the Commerce Commission's attention to the unsuitability of some of the railroad equipment now used in the Midwest and asking that at least half the coal cars built in the future be flat bottoms. A committee was appointed to study the feasibility of a state license system for retail coal dealers.

The association was addressed by L. P. Coan, an old-time St. Louis coal man, and by Walter Heinecke, D. H. Derbster, Arthur Hull and W. R. Schneider. A banquet wound up the one-day convention. The officers elected for the coming year are:

President, R. D. Kelly, Springfield, Mo.; first vice-president, W. A. Storrs, Hannibal, Mo.; second vice-president, H. R. Oglesby, Warrensburg, Mo.; third vice-president, F. W. Schramm, Farmington, Mo.; fourth vice-president, S. P. Guthrie, Mexico, Mo.; secretary, James P. Adriano, St. Joseph, Mo.; treasurer, F. L. Keightley, 1616 S. 39th St., St. Louis; commissioner, E. J. Wallace, Pierce Bldg., St. Louis.

Next year's convention will be in Springfield, Mo.

Ralph Clements Arrested On Fraud Charge

Ralph Clements, of Cleveland, former president of the defunct Valley Coal & Dock Co., Milwaukee, was arrested in Cincinnati recently charged on 19 counts by the federal grand jury with using the mails to defraud.

With him was named Bertram M. Ainesworth, Milwaukee, alias Bertram M. Altheimer, who is believed now to be a fugitive from justice. Clements was arraigned before a court commissioner in Cincinnati and upon entering a plea of not guilty was released on \$2,500 bonds.

The officers caused to be issued 10,000 circulars and numerous financial statements from time to time to creditors and coal operators from whom they solicited credit in which they claimed they had taken over the entire assets of the Valley Coal Co. and that the new capitalization was then in excess of \$300,000, paid in cash, when in fact they did not have any paid-in cash capital whatsoever.

Northwest Rate Changes Are Delayed a Month

Although the Interstate Commerce Commission ordered higher rates from southern Illinois into the Northwest to take effect Aug. 21, a 30-day postponement already has been granted at the request of the railroads, and the lines are asking for another 30 days. They claim the complicated business of making new rate schedules and issuing the tariffs cannot be done even by Sept. 21 and that the date should be Oct. 21.

Thus begins the expected series of delays and counter movements against the new ruling which gives the Northwest docks an advantage over the all-rail shippers into Minneapolis and St. Paul and into certain other rate zones of the Northwest. The decision ordered advances of 8c. and 15c. a ton on rail coal from southern Illinois into two zones of southern Minnesota and 28c. into the Twin Cities, whose coal consumption is about half that of the entire State of Minnesota.

Bureau of Mines Awards Coal Contracts

The U. S. Bureau of Mines has awarded to the Philadelphia & Reading Coal & Iron Co. contracts for anthracite on the basis of bids opened May 28. The contracts call for the delivery during the coming fiscal year of 1,320 tons of broken at \$8.65 per ton; 5,730 tons of egg at \$9.25; 5,940 tons of stove at \$9.40; 1,650 tons of nut at \$9.25; 100 tons of pea at \$6.25, and 250 tons of red ash at \$9.90.

The only contract so far awarded by the Bureau of bituminous coal is for 54,000 tons of New River run of mine for delivery to the Government Fuel Yards, purchased from the Minter Fuel Co., Inc., Beckley, W. Va., at \$2.19 per ton.

Miners and Guards in Battle At Brady Mine

For the second time since the Brady-Warner Coal Corporation started the operation of its mines on an open-shop basis an attack was made on the mining settlement at Brady early in the morning of June 19 and four union miners have been arrested. One man was wounded during the attack, the union hall at Brady was destroyed by fire and a number of houses occupied by mine guards and non-union miners were riddled by bullets during the course of a two-hour battle.

Trouble started during a demonstration staged by an organization known as the "Regulators," to which many union miners and their sympathizers belong, according to the testimony of miners. During this demonstration dynamite was set off and then the firing of shots from a steep hillside was started. The mine guards in the settlement returned the fire and for a time there was an exchange of several hundred shots.

When Sheriff Yost, of Monongalia County, arrived at Brady the union hall was on fire but shooting had ceased. Officers found the settlement panic stricken, many of the miners and their families having hidden in cellars. The four union miners placed under arrest admitted that they were formerly in the Brady mines.

During the attack on the Brady mining settlement, the mining community of the Francois Coal Co., about three miles away, also was attacked and a few shots fired.

Samuel D. Brady, president of the Brady-Warner company, stated following the attack that "We propose to operate the mine at all hazards," adding that the constitution "gives the company the right to enjoy its property and to operate as long as the plan is within the law."

Attributes Outlaw Strikes to Disbelief in God, Gospel or Hell

The investigation into the numerous petty strikes that have tied up collieries in anthracite district No. 1 got under way in Wilkes-Barre, Pa., June 18, when five International board members, comprising an investigation committee appointed by John L. Lewis, International president of the United Mine Workers, heard testimony from district union officials on the causes ascribed for the outlaw strikes.

Rinaldo Cappelini, president of District 1, threw much light on the underlying cause of the outlaw walkouts in the following statement to the committee: "Almost every morning when I get out of bed I read in the papers of another unauthorized strike called by a local union or a general grievance committee. There are men in District 1 who do not believe in God, the gospel or hell, and these men

would do anything. There are several nests of I. W. W. in the district and other miners, believing it will be a nice day tomorrow and who want to go fishing, strike or declare a holiday. This must be stopped if the United Mine Workers are to act as a unit."

Cappelini also declared that the refusal of company officials to hear grievances has resulted in several strikes.

The investigation will continue into this week, with a session in Scranton. Many district officials will be called before the investigating committee, and it is also expected that alleged radical leaders in the Pittston field will be summoned for examination.

No hint has been given as to the resultant action of the committee following the probe. It is understood that a full report of the investigation will be turned over to President Lewis.

Practical Pointers For Electrical And Mechanical Men

Minor Changes to Locomotive Reduce Haulage Costs Ten Cents a Ton

Storage-battery locomotives have filled a great need for some form of haulage equipment which may be used more safely than a trolley locomotive near the coal face. However, they have other advantages, especially where the expense of bonding rails, installing trolley and feeder lines would be large.

In low coal, battery locomotives obviate the necessity for blowing down roof rock or taking up bottom in the haulageway. Even if height were made so as to give minimum headroom for the trolley wire it nevertheless would be so low as to be dangerous to the workmen and that fact probably would cause annoying delays to the system whenever a car jumped the track and grounded the circuit or tore down the wires.

Another advantage of the storage-battery locomotive, which will become increasingly more important as years go by and thinner beds must be mined, is the fact that it may be made small. Mining costs in some mines largely depend upon the width of the roadways. A wide locomotive requires so much room to turn curves that it is frequently necessary to do much special and expensive mining work to accommodate them.

At one of the Pennsylvania Coal and Coke Corporation mines near Cresson, Pa., a saving of 10c. a ton was made in one section by decreasing the width of a locomotive. Originally the locomotive was equipped with outside wheels but had a relatively wide bearing housing as shown in Fig. 1.

By reducing the width of the housing 2½ in. and obtaining a narrower roller bearing to suit, the total width of the locomotive was reduced 5 in. Upon further inspection it was found that another reduction of 1 in. could be obtained by shortening the inside hub of the wheels. By doing this the hous-

Fig. 2—How Housing Was Narrowed and Wheels Relocated

A new type of roller bearing was obtained for the narrower housing and the inside wheel hub cut off to reduce the total width of the locomotive 6 in.

ing fits closer to the recessed part of the wheel as shown in Fig. 2. By making other changes to the driving axles, bumpers, side frames and battery boxes the width of the locomotive was reduced 6 in.

Keeps Controller Fingers and Segments from Burning

There are two essentials to the satisfactory and economical operation of controller fingers. They are lubrication and contact pressure.

Large-capacity fingers, ¾ and 1 in. wide, are made of copper and slide over copper contact segments. Both finger and segment, being of the same composition and comparatively soft, will wear excessively unless properly lubricated. The quality of lubricant used varies somewhat with the climate and temperatures, but vaseline will be satisfactory for summer and for moderate winters, and engine oil is satisfactory during cold seasons.

It has been general practice in the past to use large quantities of lubricant, with the idea that the more used the longer it will remain on the contact segments. This is erroneous, as the surplus soon wipes or burns off and accumulates on arc barriers, fingers and drum castings, collecting copper dust and dirt, with a resulting tendency toward insulation failure. The contact segments also become sticky and dirty. The best practice is to spread the lubricant as smoothly over the segment as possible with a cloth, operate the controller fingers over the segments several times, and then wipe around the finger and the segments to remove any surplus.

The preceding information is pri-

marily for fingers and segments for arcing duty. Where non-arcing duty is performed, much less lubricant can be used, and it should be of a lighter grade. Contact segments and fingers become roughened by arcing and should be carefully smoothed up with emery or a file before lubrication is applied. Contacts usually start cutting in two or three days. A wire-drawn contact surface should be carefully smoothed and wiped off.

Small fingers, ¼-in. and ⅜-in. wide, are usually made of different material from the contact segments, thus causing less cutting.

The safe current density on a finger depends on the width of the contact surface, the pressure at the point of contact and the mass and radiation of the finger and segment. The capacity for a given width increases with the pressure, but too heavy pressure causes excessive wear and stiff controller drums.

Average practicable finger pressures for general service, copper fingers on copper segments, are listed below. For different contact materials these values may be increased somewhat.

Sizes of Finger in Inches	Pounds Pressure
1	8
¾	6
½	4
¼	2

By means of a small spring balance and a wire stirrup the pressure is easily checked, as shown in Figs. 1 and 2, and inspectors soon become accustomed to the feel of a finger with correct pressure.

Figs. 1 and 2—Testing the Pressure of Contact Fingers

Depending upon its width a finger should have a pressure of from 8 to 2 lb. This pressure should be measured when the finger is making contact with a segment. Otherwise incorrect results may be obtained. The finger is usually resting against a stop when not making contact on a segment, and therefore may be quite loose.

Fig. 1—Original Arrangement of Bearing Housing and Wheel

Although the locomotive had been equipped with outside wheels so that the overall width would be small, the bearing housing was unusually wide and could be greatly reduced.

Pressure is varied by changing the bend in the flat finger spring. After bending see that the finger is making contact along its full width. Most fingers have an adjustable stop, which limits the drop of the finger tip when it leaves the contact, but this stop does not vary the finger pressure. Its sole purpose is to prevent stubbing. The drop should be set at $\frac{1}{16}$ -in. to $\frac{1}{8}$ -in. or enough to allow the finger to lift entirely free from the stop when the finger is on the contact. This allows full pressure at the contact surface. The lift should be checked in all positions of the drum, as an eccentric drum, or one having worn bearings and shaft may have good finger pressure in one position and weak pressure in another.

The considerations just mentioned are equally important when installing new fingers or contact segments. A new finger should preferably be ground in with emery cloth to give a contact area at least $\frac{1}{8}$ -in. in width along the contact line, and the finger should make contact over at least three-fourths of its breadth. Drum-controller maintenance cost can be kept at a minimum and failures reduced by keeping in mind these simple instructions.

Theory of Transformers

A transformer is an electrical device used to change alternating current from a given voltage value to alternating current of the same frequency but different voltage value. Generally this device is distinguished from a rotary-

Fig. 1—Construction of Transformer

The usual type of transformer consists of two separate windings. One coil generally consists of many turns of fine wire and is called the high voltage winding; the other coil consists of heavier wire and is called the low voltage winding. The magnetic linkage from the coil to which power is supplied to the other coil produces the secondary voltage.

converter or rectifier, which changes alternating current to direct current, or vice versa by being termed a static transformer.

Transformers are therefore used to raise or lower the voltage of alternating-current circuits. Their principal application is in the transmission and distribution of alternating-current energy. Aside from this transformers are used for regulating voltage and for measuring purposes.

By means of transformers, we may transmit large amounts of electrical energy at high voltages which permit the use of small wires correspondingly long without prohibitive expense for copper, line construction or excessive loss of energy. At any point along such a line where we may need power it is only necessary to tap on a trans-

Fig. 2—Core-Type Unit

In this construction the coils surround the laminated iron core. This arrangement is similar to Fig. 1, however, the two coils are usually built one inside the other.

former and change the voltage down to any desired value.

Structure of the Transformer.—A transformer consists of two independent mutual induction coils of insulated wire, strap or bar placed on an iron core. One coil is called the high-voltage winding and the other the low-voltage winding. See Fig. 1. One or the other of these windings is connected to a source of alternating current and the other delivers alternating current to a given load. Irrespective of whether it be the high- or the low-voltage winding, that coil which is connected to the source of power is called the primary and the other the secondary.

Principle of Operation.—The alternating-current flowing in the primary winding produces in the iron core an alternating magnetic flux which links with the secondary winding and produces in it an induced alternating-current voltage. By properly selecting the number of turns of wire in each coil a transformer may be designed to raise or lower a voltage of any value to another of any desired value. When a transformer is used to change a voltage to another of lower value it is called a "step-down" transformer and when it is used to raise a voltage it is called a "step-up" transformer.

Core-Type and Shell-Type Transformers.—Transformers are made in two general types; core-type and shell-type. The first construction, the so-called core-type, is shown in Fig. 2. The primary and secondary windings surround the core, and are placed as close as possible to each other in order to obtain the most effective inductive action and to minimize the magnetic leakage. A shell-type transformer is one in which the iron core surrounds the coils as shown in Fig. 3. The de-

Fig. 3—Shell-Type Construction

Note that the iron core mostly surrounds the coils. The theory of operation is the same as for the core-type transformer and the windings are generally built in sections laid close to each other.

tails of construction are very similar to the core-type transformer. Electrically the two types are the same, the difference being merely in the mechanical construction. Both types are generally made by all manufacturers.

It will be noted in most diagrams representing transformers that one winding is shown as a coil of many turns of fine wire and the other as a coil of fewer turns of coarse wire. This is because a certain amount of power at high voltage and low current would require a small wire, while the same amount of power at low voltage would necessarily be of high current value and require a relatively larger wire.

The cores of transformers are made of thin sheets of special non-ageing iron cut to shape and stacked together. This is necessary to keep the transformer losses as low as possible. The rapidly reversing magnetic flux in the core produces both a hysteresis and eddy-current loss which is large or small depending upon the kind of iron and thickness of the laminations.

Methods of Cooling.—Depending upon the type, kind, size and service a transformer may be cooled by natural radiation, oil, water or air blast. Metering transformers and transformers used for short intervals of time such as motor starting transformers are often cooled by natural radiation. Most all other transformers are immersed in oil which dissipates the heat or is assisted by water-cooled coils near the surface of the oil. Air-blast cooled transformers are only feasible in central and substation practice where a suitable air-blast fan can be installed.

Don't Lengthen Your Wrench

I have several times seen in print the kink which shows how to make a wrench longer by "slipping a gas pipe over the handle." It is a simple procedure, and it may look and sound good to some, but I don't believe in making a wrench longer in order to tighten nuts.

Wrenches for small nuts are invariably short; for medium nuts, medium in length; and for large nuts, they are long. The manufacturers have some system in making wrenches. The pitch of the thread, the cross-sectional area of the bolt at the bottom of the threads and the strength of the man who does the tightening are all considered in the design of the wrench.

By making a wrench twice as long you therefore double the twist on the bolt when the pull on the wrench is the same. By increasing wrench lengths I have frequently actually stretched bolts until they broke in two, unless I stopped turning as soon as I thought the bolt was beginning to stretch. This is poor practice, and I do not do it any more. I do not increase the length of the handle because I realize that the elastic limit of a bolt should never be reached.

If you feel like making a wrench longer for unscrewing a nut do so. But don't make it longer for tightening.

W. F. SCHAPHORST

Production And the Market

Bituminous-Coal Trade Begins to Take Hope As General Business Shows Signs of Upturn

Straws showing which way the zephyrs are headed are to be seen in the heavier dumpings at Hampton Roads and at the Lakes as well as in the increased movement to tidewater at New York. The increases do not amount to much in themselves, but as premonitory symptoms of the long-awaited turn for the better in the coal business they are fraught with far-reaching interest. As during the nationwide depression of the last few months, the coal situation reflects general business conditions, which are reported to be gradually improving. There has been no change in the textile and shoe industries, which are at an extremely low ebb, but a turn for the better in the steel trade is looked for soon. A prominent coal operator predicts an increase in coal production within thirty days, saying there will be a spurt after July 1 to replenish dwindling stockpiles, which are nearing the danger line.

Bureau of Mines Places Orders

The U. S. Bureau of Mines has awarded a contract for 54,000 tons of New River run of mine coal, to be delivered to the Government Fuel Yards, at \$2.19 per ton. Contracts for several small lots of anthracite, totaling 14,990 tons, also have been let.

Coal Age Index of spot prices of bituminous coal failed to register any change during the week, standing at 166 on June 23, the corresponding price being \$2.01, the same as on June 16.

There was a pronounced pick-up in activity at Hampton Roads, dumpings of coal for all accounts during the week ended June 21 totaling 350,821 net tons, as compared with 265,222 tons during the preceding week. Coal dumped at Lake Erie ports during the week ended June 21, according to the Ore & Coal Exchange, was as follows: Cargo, 699,519 net tons; fuel, 41,168 tons. The previous week's figures were 645,978 tons of cargo coal and 39,184 tons of fuel coal.

Production of bituminous coal again took a tumble during the week ended June 14, the upturn of the preceding week proving to have been only a post-holiday spurt. Output for the week ended June 14, according to the Geological Survey, was 6,999,000 net tons, a decrease of 374,000 tons from the week before. Nevertheless, there has been a tendency toward a gradual increase in the rate of output since April 12, and the Geological Survey reports that telegraphic returns of car loadings for June 16 and 17 indicate the probable continuance of this slow recovery. Anthracite produc-

tion also declined slightly, the output for the week ended June 14 being 1,823,000 net tons, compared with 1,846,000 tons during the previous week.

Activity in anthracite continues to taper off steadily. Demand is gradually but surely slowing down, consumers showing a disposition to hold out for the particular size they want and refusing a mixture of chestnut in order to obtain stove. Demand is still far the strongest for stove, though there is a fair call for egg. The movement of pea has slowed down to such an extent that some operators are reported to be storing it in large quantities.

Estimates of Production

(In Net Tons)

BITUMINOUS

(a) Revised from last report. (b) Subject to revision. (c) Minus one day's production to equalize number of days in the two years.

Midwest Hunts Market

The deadly dullness shows no new signs of brightening. The scattering inquiries of a week ago continue to come in, thus giving some encouragement to an otherwise sluggish trade, but little business is developing out of it and none is expected now for a few weeks. However, the trade is not so much pessimistic as it is callous to hard going. From now on, any change will be for the better. Heat waves sweeping the middle belt of the nation have killed retail business and few yards are stocking with Midwest coals. There is a little constant business for eastern Kentucky and smokeless coals among such buyers.

Steam trade is slower. For the first time screenings "no bills" are beginning to accumulate at some of the mines of Illinois and Indiana. This aggravates the tendency to lower steam prices which began last week. Little southern Illinois fine stuff brings more than \$1.90 and most of it is clear down to \$1.75. Fourth Vein Indiana is at the same level. Fifth Vein and central Illinois screenings range from \$1.50 to \$1.65 with emphasis on the low figure.

The Illinois fields show no improvement in running time. Crushers are busy making small coal out of large. Commercial mines hardly ever get more than two days' work a week. Railroad tonnage generally is light in the southern

Illinois regions but continues moving slowly in the Mt. Olive territory. Standard district mines are hardly able to sell anything. The region is full of empty storage cars and a good many "no bills." Little smoke rises from mine plants.

Business is practically at a standstill in St. Louis. No domestic coal is moving except for current needs and that is small. Storage does not seem to have begun. Dealers' yards are well filled with everything. Both wagonload and carload steam business has stopped. Country domestic shows a little activity but it is hard to find, and country steam, which was active two weeks ago, has eased up. There are no changes in prices.

Kentucky Foresees Stocking Demand

The feeling in the Kentucky coal trade is somewhat better than it has been, as it is felt that the worst of the dull season is past and that normal summer stocking will now create a demand for coal. Domestic sizes are moving better, and this with Lake business is resulting in better production of screenings and slight weakness in the market for those sizes. This should influence some of the big steam consumers to place orders. In eastern Kentucky screenings are selling at from 85c. @ \$1.15, as against \$1.25 @ \$1.50 in western Kentucky.

Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines

	1924	1924	1924	1923
	June 23	June 16	June 9	June 25
Index	166	166	170	205
Weighted average price	\$2.01	\$2.01	\$2.06	\$2.49

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913-1918," published by the Geological Survey and the War Industries Board.

Prepared prices are very steady at from around \$1.75 for egg to a peak price of \$2.75 for best 4-in. block in eastern Kentucky. Eastern Kentucky mine run is steady at \$1.35 @ \$1.75. Other than a little weakness in western Kentucky screenings, prices have been very firm throughout the Kentucky coal fields over the week, eastern Kentucky having lost 5c. or so from the low on screenings.

Southern West Virginia mines are now producing as much tonnage as they sometimes do under more favorable market conditions. There has not been any further increase in the high-volatile output and yet about 600,000 tons per week is coming from the mines, more than half of which is originating in the Logan district. Shipments from Logan to the lakes is unusually large. Comparatively little high volatile is being consigned to Eastern markets owing to the extremely low prices prevailing in that section of the country. There is a little more mining activity in the smokeless area, the average working time being around three days a week.

Prices Drop at Duluth

Trade at the Head-of-the-Lakes is virtually at a standstill, with the railroads supplying some of the activity in out shipments, and a few small orders from industrial concerns which are buying from hand to mouth supplying the balance. Arrivals keep up to the mark, however, with 21 cargoes landed during the week, of which two were hard coal. It is estimated that this market will be strong in hard coal this year and that 1,400,000 tons will be needed to meet the demand. Of this only about 65,000 tons has been brought up so far. The Steel Corporation is moving coal up again, which is a good omen.

Prices have taken a tumble in bituminous as shown in this circular list: Kentucky lump, \$6.25; run of pile, \$5.75; screenings, \$4.25; Youghiogheny lump, \$5.75; run of pile, \$5; screenings, \$3.75 @ \$4; Hocking lump, \$5.50; run of pile, \$4.75; screenings, \$3.75; splint lump, \$5.50 @ \$5.75; run of pile, \$5; screenings, \$4; Pocahontas lump, \$7; run of pile, \$5.50; screenings, \$4.50.

The only sign of real life in the market is the bidding which is being done for municipal contracts among the towns of the iron ranges. It is asserted that docks are sticking fairly close to prices in this.

Summer dullness pervades the Milwaukee coal market. Retailers profited in a small way by prolonged wet and cool weather, but everything is quiet now. There is little doing in the wholesale trade. The soft-coal market is weak. The regular price of Youghiogheny pile run, f.o.b. car or truck, is \$6 a ton. The United Coal & Dock Co., however, is delivering 2,000 tons of this coal to a Milwaukee institution at \$4.49. Other bids ranged from this price up to \$5.31 per ton. Last year the county paid \$6.19 for the same coal. Oil is affecting the anthracite trade quite seriously. June witnessed quite a spurt in receipts by lake, but midsummer promises to be slow in this respect. Receipts of anthracite for the season aggregate 210,398 tons, and of soft coal 474,420 tons.

Western Business Is Slim

Little activity is reported through the Southwest. Domestic storage, principally of Arkansas semi-anthracite, has started, but is slow. There has been a steady increase in the pre-season demand for threshing coal. The industrial demand remains quiet. Retailers are making a storage price of \$10.85 on Arkansas semi-anthracite lump, from \$2 to \$2.50 below the regular midwinter price.

The demand for Colorado coal continues very quiet with mines working two or three days a week, which, in the opinion of the operators, is hardly worth while. Although many of the smaller mines have been closed entirely, very little improvement is shown in the production of the others. Operators report 42 per cent of the working time lost last week on account of no market. Prices are unchanged.

Mines in Utah are working less than two days a week. The demand, such as it is, is for intermediate sizes. The sugar industry is storing a little slack coal, however. There is no contracting right now, but a few bids have been published. It is thought that screened slack will soon be off the market as a result of the new mine regulations, which will make it difficult to get this grade hereafter. Price cutting is reported, especially on slack coal, which is said to be selling as low as 90c., though \$1.25 is supposed to be the price.

Cincinnati Sees Cheering Signs

Better demand for bituminous nut and slack was the high point of Cincinnati market this week. Inquiry and orders came largely from industrial plants, some of which had been out of the market off and on for several months. Lump and block business has slowed down considerably, due in great measure to the torrid days that have set in and inability to get raw labor to handle the shipments to the smaller places. In the smokeless line-up the principal cause for comment is the strength of prepared and the weakness of the residue. The undertone is better, the belief being that the worst of the situation has been seen. River business, because of the excellent stage, is good. Retail prices show no change.

The trade at Columbus continues quiet, but some producers and shippers profess to see signs of improvement. Signs of a better demand from retailers are apparent and buying is slightly heavier. Householders show a preference for Pocahontas, splints and Kentucky grades, although some Hocking and Pomeroy lump is moving. Steam business is rather quiet with prices low and irregular. Utilities and railroads probably are the best customers now, although iron and steel concerns also are buying to a small extent. School coal is moving in good quantities. Contracting is quiet, as most users are content to buy on the open market in preference to renewing contracts. Demurrage coal is not so common since many of the larger mines have closed down. Loading of bottoms at the lower lake ports is rather brisk, but Kentucky and West Virginia are getting the business.

Shippers to the Cleveland market are pessimistic, believing the hoped-for upturn still distant. Prices have eased off a trifle further, the general tendency being weaker. No doubt this is due to the tapering off of industrial and manufacturing activity and a tepid demand for Lake cargo coal. Distress coal arriving at industrial centers unconsigned is being disposed of in small lots at 5c. to 10c. under the market to avoid demurrage charges.

Consumption of coal at Pittsburgh continues to trend downward, both on the railroads and in the industries. The steel industry, however, probably is not far from its turning point now. There is no change in quotations except that slack is down about 10c. for both steam and gas.

The trade at Buffalo is quite as dull as ever. The offices of operators whose mines are shut down are little now but hanging-out places, unless they go into the jobbing trade, which some of them have not done. The general slowing down of business has given the coal trade a second downward turn.

Better Undertone in New England

While there is no marked improvement in New England trade there is perhaps a less unsatisfactory undertone than a fortnight ago. Prices are reasonably well maintained at the levels quoted last week and there is less shading of spot quotations. There are of course as yet no signs of comprehensive buying, but current inquiry is being closely watched and especially for inland delivery from rehandling wharves at this end there is a disposition to net more money the moment the situation warrants. It is noticed, too, that all-rail coals are in somewhat better request in the territory where they are accessible in competition with Pocahontas and New River.

At Hampton Roads the No. 1 grades are being held at \$4.25@4.40 per gross ton f.o.b. vessel, and here too there are fewer indications of price shading. Smokeless coal of No. 2 grade is still to be had at levels down to \$4, but accumulations are less heavy and output generally is being rigidly curtailed. There is enough tonnage applying on contracts and on purchases offshore to take care of a fairly good proportion of the Pocahontas and New River now being mined.

For distribution at Boston, Providence and Portland prices are still nominally \$5.75 per gross ton on cars; \$5.50 coal is less heard from and there are more quotations of \$5.65 than has hitherto been the rule. This situation naturally improves the prospect for higher grade coals all rail from central Pennsylvania and there have been several instances lately where rail coal has been sold in areas that have been regarded this season up to now as practically closed to the rail route. In this quarter also there is an inclination to advance prices mildly, although as yet not more than 5c. or 10c. more has been paid even on the choicest grade.

Outlook Brighter on Atlantic Seaboard

While no one is willing to admit that business shows a slight improvement the fact remains that shipments of soft coal to the New York tidewater during the past week show an improvement. Receipts for the first five days of the week indicated a daily average of about 1,500 cars whereas for the past few weeks the average has been between 1,300 and 1,400 cars. No one would give an opinion as to why the extra shipments were made in view of the low prices prevailing. There is a better feeling, however, and, while the order books do not show it, the outlook is becoming brighter. Consumers continue to use their re-

serves rather than follow the advice of the federal authorities and railroad officials to stock up before the fall rush begins.

Calm has overspread the trade in Philadelphia. Rumors of strikes in regions where efforts are being made to cut the union scale, it was thought, might spur consumers into buying coal, but so many of them are now contending with poor business prospects that they pay scant attention to their coal supply. Prices remain firm.

A renewal, in some measure at least, of the export movement, along with the announcement that a fair number of charters are now being made for loadings over the end of June and the first part of July, is probably the most encouraging feature of the situation at Baltimore. Local demand is confined almost entirely to small immediate needs. The city government plans the substitution of lump bituminous for anthracite in school houses, fire department houses and other city buildings now being heated by anthracite.

The Birmingham market continues to be much depressed and no indications of improvement are in sight. Slowing down in operations at industrial plants throughout the territory has caused a restricted demand for steam coal in the spot market, and sales agencies and operators are receiving requests to defer regular shipments against contracts. Production is being gradually decreased to accommodate the dull market.

Anthracite Market Still Losing Zip

Stove coal continues to hold the other domestic sizes of anthracite in line at New York, thereby preventing a marked drop in independent quotations. Demand centers almost entirely around stove size, although there is a fair demand for egg. Movement of hard coal is slowing gradually. Demand is much slower, and consumers are maintaining an attitude of demanding the size wanted and of refusing to take a mixture of stove and chestnut when the former coal is wanted. Chestnut is the longest of the three sizes and is quoted at lower figures than either egg or stove when taken alone. Egg coal brings a better price when it is not taken in conjunction with chestnut, which is not in good standing in the New York market. Pea moves slowly. There is a lull in the demand and some operators are reported as storing heavy tonnages. Demand for the steam sizes has slackened considerably. Only the better grades of independent No. 1 buckwheat are bringing full company circular, the average maximum hanging around \$2.75. Rice and barley are in better movement.

At Philadelphia the hard-coal trade has slowed down to a marked degree with the appearance of the first warm weather. Ordering has almost ceased and the public has quickly lost interest in coal. Stove and egg are most in demand, but much of the edge has been worn off these sizes. There are numerous dealers who want more of this coal, but balk at taking nut and pea to get it.

Despite a well organized campaign on the part of a number of Baltimore dealers to induce customers to place orders early, there has been no general response. The fact that the public is fairly well acquainted with the virtual certainty of a retail increase on July 1 seems to have but little effect.

Foreign Market And Export News

British Coal Market Reviving Slowly; Output Slips Further

The British coal markets are gradually reviving from the usual depression that accompanies the holidays, but new business is scarce. Quoted prices are being shaded in some instances to obtain orders. It is reported that German and American competition is keener. The South Wales market reflects a slight improvement in demand. Exports are expanding and the attempts of foreign buyers to depress prices are not meeting with success. Notices of approaching shutdowns have been posted at additional pits as a result of the unremunerative operating conditions.

A cable to *Coal Age* states that the production by British collieries during the week ended June 7 was 5,120,000 tons, according to the official reports. This compares with an output of 5,308,000 tons during the week ended May 31.

House Trade Dull, Industrial Demand Normal in France

Business in household coal in the French market is dull. Activity in industrial fuels, however, is normal and satisfactory, but there is no rush on the market and deliveries are quite regular. Increased output from the devastated collieries is being placed without difficulty.

In the import field there is much surprise in seeing prices raised at the British shipping docks at the same time that the pound is rising; ordinarily French dealers expect some compensation. Owing to the unsteadiness of exchange, there is much hesitation in the purchase of British coals. However, some exporters are making offers in pounds based on a certain rate and provide in their contracts a stated difference per ton applicable per point of increase in the value of sterling on receipt of the order.

From Belgium deliveries are plenti-

ful and the transportation problem seems less acute because shipments are less abundant.

Deliveries of indemnity fuels remain weak as compared to the tonnages received before the strike. During the first seventeen days of May, France and Luxemburg received 156,700 tons of coal, 248,100 tons of coke and 15,770 tons of lignite briquets, a total of 420,620 tons, or a daily average of about 24,800 tons. Although no statistics have been given out on the amount of fuel received during the last days in May, the deliveries are said to have fallen off. It is hoped, however, that they will soon improve with the gradual resumption of work in the Ruhr mines. But, as the amount of fuel that should have been delivered to the Allies has not been received, the Reparation Commission has seized stocks at the mines.

The Dusseldorf agreements having expired on June 15, negotiations will be started as soon as the new French Ministry for Public Works is appointed.

Hampton Roads Sees No Let-Up In Dullness

Dullness continues to feature the market at Hampton Roads, with supplies at tidewater dwindling but with the price level holding steady. A large contract for South American shipment has been wound up, leaving the foreign movement outlook unpromising. Coastwise movement is only fair, while the bunker trade is holding its own.

Washouts on the Virginian Ry. have caused a delay of several days in coal movement and have tended to curtail output to some extent, being partly responsible for the low supplies at tide.

The tone of the market is dull and the outlook is described by shippers as not bright, although they had expected a slow spell at this season.

New Coal-Loading Plant at Brazilian Port

Pernambuco, Brazil, is to have a new mechanical coal-loading plant, which will be installed at an expenditure approximating \$287,000. A traveling gantry crane will be used to deliver coal on shipboard by clamshell buckets, or other similar device. A minimum loading capacity of 250 metric tons per hour is contemplated.

News Items From Field and Trade

ALABAMA

The Alabama Coal & Iron Co. has given an option on 158,000 acres of coal lands in Etowah, Jackson, Marshall, Cherokee and DeKalb Counties to the Jasper Trust Co., of Jasper. The Etowah Investment Co., which owns a large tract of coal lands in the western part of Etowah County, also has given an option on its holdings to the same company. The Jasper Trust Co. is the holding company for the Deepwater Coal & Iron Co., recently organized with a capital stock of \$10,000,000 and with headquarters at Jasper. The company is preparing for the extensive mining of coal at a number of places in northern Alabama.

A new board of state mine examiners has been appointed by Governor Brandon as follows: F. G. Long, Maylene; Sam Y. Leith, Dolomite; C. M. Parker, Newcastle; J. S. Kellum, Boothton; C. E. Bowron, Birmingham, with C. H. Nesbitt, chief mine inspector, as ex-officio chairman. The board will hold an examination of applicants for eligibility as mine foremen and fireboss during the latter part of July, the date not having been fixed as yet.

The Gadsden Coal & Clay Products Co. has been incorporated at Gadsden and will mine coal from a new opening near that point and also will remove a vein of fireclay underlying the coal, the clay to be used in the manufacture of brick. E. N. Smith is president of the company.

COLORADO

Edward H. Denny, formerly of the Bureau of Mines safety section, in Washington, has succeeded Dan Harrington as the bureau's district mining engineer for Colorado, Wyoming and New Mexico. He is already on the job, with headquarters in Denver. Mr. Harrington now lives in Salt Lake City, Utah, and is consulting safety engineer for two Utah coal companies.

CONNECTICUT

The Commonwealth Fuel Co., of Pennsylvania, has been granted \$73,856.65 damages against the Karm Terminal Co., at Bridgeport, one of the largest dealers in coal in Connecticut. Mr. McNeil, of the Karm Terminal Co., has filed notice of appeal.

NEW YORK

W. C. Atwater, president of Wm. C. Atwater & Co., Inc., New York City, has been elected president of the Pocahontas Operators' Association, suc-

ceeding Isaac T. Mann. Mr. Atwater has been in the coal business nearly 30 years, beginning as a salesman in 1886 and taking over a retail yard at Fall River, Mass., two years later. He soon entered the producing field, being first associated with W. D. Ord in the Empire operation and later purchasing the Elkhorn mines at Maybeury. The holdings of the firm of Wm. C. Atwater & Co., established in 1900, now include the Elkhorn operation, the Fall River Coal Co., the Williams-Pocahontas Co. and an interest in the American Coal Co.

The city of Buffalo has given up the use of anthracite for school fuel and asked for bids to furnish 26,000 tons of smokeless bituminous and 10,000 tons of ordinary soft coal. This will provide supply from July to April.

The name of the Maxim Coal & Coke Corporation, Buffalo, has been changed to the McCarthy Coal & Coke Co., a copartnership, with D. J. and F. H. McCarthy owners, L. P. Zimmerman having retired.

The Lehigh Valley Coal Co. in 1923 had a net income of \$5,237,083 after bond, interest and federal taxes, against an average net of \$3,651,935 for the five years to Dec. 31, 1923. This was equal to \$4.32 a share on the 212,160 certificates of interest offered to stockholders of the Lehigh Valley R.R., compared with \$3.01 a share for the five-year period. The company's deduction for bond interest did not include provision for any interest on \$15,000,000 of 5 per cent bonds for the reason that the issue was dated Feb. 1 of this year and did not enter into the financial structure of the company during 1923. Interest on this issue for the eleven months of the current year will be a charge against this year's income.

OHIO

The New Pittsburgh Coal Co., of Columbus, announces that the Minerton mine, in the Pomeroy field, will not be abandoned, as reported, but the tonnage will be run through the tippie of the Thomas mine, which adjoins.

The federal court at Covington, Ky., has named William S. Harmon and Frank L. Stein, both of Columbus, ancillary receivers for the Maynard Coal Co. They had been named by the federal court in Ohio upon the original application. A considerable holding of the company is located in the Hazard field of Kentucky.

One of the few coal saleswomen,

Mrs. G. W. Kuhn, secretary-treasurer of the Big Mountain Coal Co., which has offices in the Hadden-Clinton Bank Building, Columbus, has been on the road at various times this spring and has disposed of quite a tonnage. Recently she made a trip to Toledo, Detroit and Cleveland.

The Marcoll mine of the Maher Collieries Co., near Powhatan, partly completed, was the scene of an explosion June 12, which wrecked the shaft, hurled the mine cage to the level of the surface from the bottom of the 200 ft. shaft and tossed safety doors to earth. There was no one in the mine at the time of the explosion, about half an hour before engineers had planned to enter the mine in order to make a survey. The explosion is believed to have been caused by an accumulation of gas. Not quite a year ago William Maher and his brother, sons of the head of the Maher Collieries Co., of Cleveland, were killed in an explosion in the same mine just as they were preparing to enter the mine after descending to the bottom of the shaft.

As soon as estimates of the amount of coal needed are received, John E. Harper, Director of Public Welfare, will ask the State Purchasing Agent to advertise for bids and the contracts for coal for Ohio state institutions during the next 12 months will be let. The State uses more than 150,000 tons of coal annually, and, following the order of Governor Donahey, all of this is Ohio-mined coal. No coal from out of the state has been purchased in the last two years, and all contracts are let on competitive bidding. It will be impossible to award the contracts before July 1, when the appropriations for the next fiscal year will be available, but Director Harper will have all requisitions in before that date, and there should be no delay in placing the order.

PENNSYLVANIA

The Mather Colliery Co., in Greene County, followed the lead of a number of the large coke region companies and reduced wages last week to the 1917 scale.

Coal mining men of the anthracite region are much interested in the segregation of the Lehigh Valley Coal Co. from Coxe Bros. & Co., which must be effective March 15, 1926. The Coxe lands were operated by the Coxe family for many years, but about twenty years ago the Lehigh Valley took the collieries over. If the Valley loses the Coxe holdings, its operations in the lower

field will be materially reduced. It will have only the Shaft and Hazle mines and part of Stockton, Jeansville and Yorktown, unless it reopens the Humboldt. Shaft colliery is largely dependent upon Coxe coal from the Black Creek Valley and Jeansville takes Coxe coal from Oneida.

W. J. Rainey, Inc., has blown out a few hundred ovens at a number of its Connellsville plants, but is running its mines about full, shipping more coal than heretofore. The H. C. Frick Coke Co. has reduced the running time of some of its plants to four or five days per week.

Union officials of District 7 entertained Thomas Kennedy, president, and James A. Gorman, secretary of the Anthracite Conciliation Board, at a banquet in the Hotel Loughran, Hazleton, on June 11. The honor guests left two days later for Europe, where they will attend the world labor conference.

Separate benefit funds of \$1,000 each have been contributed by the district and the international union of the mine workers to the families of the fourteen mine workers who were killed at the Loomis colliery of the Glen Alden Coal Co., Hanover Township, over a week ago.

The Buckeye Coal Co., subsidiary of the Youngstown Sheet & Tube Co., closed down its Nemaquin mine, at Nemaquin, Greene County, last week. Its Brier Hill operation in Fayette County has been down for some time, so that this company is now entirely idle in this section.

The Crawford Coal & Coke Co., of Connellsville, has enlarged its holdings by the purchase of 70 acres adjoining the present property in Georges township, Fayette County. It is reported that \$140,000 was paid for the tract, which is underlaid with Connellsville coking coal.

More anthracite is being taken from the Lehigh River and the numerous dams throughout the Lehigh Valley this spring than in many years past, owing to the continued high water, which washes the coal down the river from the collieries and culm banks along the different tributaries of the Lehigh River.

For the first time in the history of mining circles in the hard-coal region, representatives of the United Mine Workers a week ago visited the main offices of the Hudson Coal Co. in New York to take up with the president of the company and other company officials grievances presented by the local unions. In the past grievances were adjusted at the Scranton offices of the company.

Nearly a million dollars has been expended on equipment and improvements at the Candlemas colliery of the Haddock Mining Co., at Silver Brook, composed of Scranton and Wilkes-Barre capitalists, in a little less than two years, since a long-term lease was obtained from the Philadelphia & Reading Coal & Iron Co., the Lehigh Valley Coal Co. and the Coxe Estate, on a 300-acre tract. A breaker with a

capacity of 2,500 tons daily is operated by electricity; mine slopes have been put in readiness; ground has been cleared to begin stripping operations on a large scale; five steam air compressors have been installed and nearly 500 men are at work.

William Gilbert, contractor, of Hazleton, has started to drive a slope on the extreme eastern end of the Silver Brook tract, on land near O'Gara's in Quakake, controlled by the Coxe estate. This is among the few remaining tracts that can be classed as virgin coal land. The coal will be mined under a royalty distribution arrangement with the Reading, Lehigh Valley and Coxe interests owners.

While closed down the Buckeye Coal Co., a subsidiary of the Youngstown Sheet & Tube Co., is building at the Nemaquin Mine, in Greene County, a new and permanent steel tibble to replace the temporary wooden one erected when the first shafts were sunk. The company also will install skips for hoisting and is concreting the shaft bottom landing and main entry for a considerable distance therefrom.

The entire cave area over the workings of the Glen Alden Coal Co. is being equipped with a gas ventilator devised by W. W. Inglis, president of the company, to carry off gas. The ventilator is an arrangement of a terra cotta pipe placed over the service gas pipes of all houses in the district where settlement of the service mains might occur. Escaping gas generally follows the pipes and by placing a vent some distance from the houses in the district, it is declared, the gas will come to the surface instead of continuing into the homes.

Most of the fatal roof fall accidents occurring in the anthracite mines are traceable to carelessness on the part of the mine workers, it was agreed at a mine safety meeting conducted by mine inspectors and various coal company officials in the offices of the Glen Alden Coal Co., Scranton, last week. Upon motion, a resolution was adopted asking that the mine workers be represented at another conference to be held soon. Last week's conference was the second within a short time and

manifests the desire of the anthracite operators to do all in their power to prevent mine fatalities. In attendance at the meeting were State Mine Inspectors P. J. Moore, Augustus McDade, Jenkin T. Reese and L. M. Evans, and representatives of the Temple, Glen Alden, Scranton, Pennsylvania and Hillside, Von Storch, Price-Pancoast, Moffat, and Mid-City coal companies.

The State Bureau of Workmen's Compensation during the month of May received reports of 157 fatalities in Pennsylvania's industries. Of this total 62 occurred in the bituminous and anthracite mines. During the first five months of 1924 there have been 934 fatal accidents in the state's industrial establishments, and since Jan. 1, 1916, the date of the inception of the compensation law, there have been 21,402 fatal accident reports filed with the bureau. There were 108 permanent disability cases reported in May 1924, making the total for the year, up to June 1, 661. Since Jan. 1, 1916, 5,160 cases of permanent disability has been reported. In May there were also 13,832 cases of temporary disability reported, the total for the year being 73,291 and the total for the period of the act, 1,531,074. In May the Compensation Board awarded \$572,042 in fatal cases, the largest monthly total with the exception of March, when \$618,985 was awarded. The 1924 total award for fatal cases so far has been \$2,677,306 and since the beginning of 1916 the total has been \$45,822,525. The fatal compensation paid last month was \$358,607, making the total for the first five months of 1924, \$1,518,224. Since the beginning of 1916, \$16,437,964 has been paid in compensation to dependents of persons killed in Pennsylvania's industries. The disability compensation paid in May was \$691,212, making the total for 1924 up to June 1, \$3,003,347. Since the compensation system was started \$37,938,098 has been paid in disability compensation. The total compensation paid for all causes has been \$54,376,062 since Jan. 1, 1916, and of this sum \$4,521,571 was paid by the board since Jan. 1, 1924.

Approximately 900 men and women employed by the Glen Alden Coal Co. were guests of the company at a ban-

Courtesy U. S. Distributing Corp.

No. 9 Colliery, Pennsylvania Coal Co., Pittston, Pa.

At this plant is both a shaft and a slope and no less than seven seams in operation. The mines are in Luzerne County.

quet, concert, entertainment and dance in Irem Temple, Wilkes-Barre, a week ago. The affair was tendered the employees in recognition of the excellent work performed during the past year. W. W. Inglis, president of the company, presided. At the banquet a silent toast was given in honor of the fourteen men who lost their lives in the gas explosion at the Loomis colliery.

WASHINGTON, D. C.

F. G. Tryon, geologist in charge of coal statistics for the U. S. Geological Survey, is en route to London to attend the World Power Conference.

WEST VIRGINIA

The Talbott Fuel Co. has begun operations at its new mine at Arnettsville in the Monongalia County field, where it has sunk a 160-ft. shaft to the Sewickley vein. The company has about 475 acres available for development.

Operations have been resumed at the No. 5 mine of the Craw Orchard Improvement Co., at Eccles, after an idleness lasting since Dec. 15. Although the Eccles plant has been shut down for so long, the property was in readiness for operation whenever it was possible to resume.

The Central Pocahontas Coal Co., operating in the vicinity of Welch, in McDowell County, has resumed operations at its mine. The first group of miners reported for duty June 6 and by June 9 there was a full complement of men at work. It is understood that there are enough orders on hand to keep the mine running full time for a period of 30 days.

The entire crop of graduates of the department of mining engineering at West Virginia University has been absorbed by the Hudson Coal Co. One of the graduates was J. L. Orr, son of J. M. Orr, general manager of the Hudson company. Another is C. Y. Shih, of Fukien, in southern China. Both men received the degrees of Bachelor of Science in Mining Engineering this spring. Shih eventually expects to return to his native land and aid in developing rich tracts of coal land in Fukien and adjacent provinces. A post graduate student at the University was a Mr. Kwong and he too after a tour of the anthracite fields expects to go to work with the Hudson company.

At the Pinnacle operation of the American Coal Co. on Crane Creek, in southern West Virginia when a pile of slate near the tipple of the coal company exploded as the result of high water; the explosion buried a dwelling at the foot of the pile, seven people being killed. Two men of a rescue party who attempted to rescue those in the dwelling are believed to have been killed when a second explosion occurred. It was necessary to dynamite a railroad bridge in order to save the commissary and several dwellings of the Rolfe Colliery Co., also in the flooded area, where much damage was done. In many places there were such

serious washouts on the Norfolk & Western that it was not possible to use the main line either for freight or passenger transportation for several days.

CANADA

The Pacific Coast Coal Mines, which formerly operated the Morden mines, near South Wellington, B. C., is being reorganized and is expected to resume shipment this fall. The Morden mine is one of the best equipped on the coast. The company, which has been in liquidation also owns a coal concession at Hequach, near Alert Bay, where some development work has been done.

The possibility of Nova Scotia Coal providing a solution of Ontario's fuel problem was given a general canvass at a conference in Toronto last week between Premier Ferguson and representatives of Nova Scotia coal interests. The meeting was arranged by Premier Armstrong of Nova Scotia and strong representations were made by the eastern representatives of the ability of Nova Scotia Mines to aid fuel conditions in Ontario.

The Dominion Government has established a minimum price at which coke may be bought by buyers in the Province of Ontario. The established rate is \$7 at Black Rock and \$7.50 at Detroit for any kind or size of coke. The regulation was passed, it is stated, at the instance of the Hamilton By-Product Co., which alleges that it cannot manufacture the product and sell at a lower price. Seventy-five per cent of the coke coming into Ontario is used for domestic purposes, which means that the government is penalizing the domestic consumers for the benefit of a plant which does not produce 2 per cent of the coke consumed in Ontario.

Output of coal from Canadian mines during March was 1,537,000 net tons, an increase of 25 per cent over the tonnage for the previous month and 15 per cent above the average for the month for the five preceding years. The output showed an increase of 352,000 tons in Nova Scotia, but decreases of 14,000 tons in Alberta, 13,000 tons in British Columbia, 7,000 tons in Saskatchewan and 3,000 tons in New Brunswick. The cumulative output from all mines for the first three months of 1924 was 4,282,000 tons, an increase of 3 per cent over the preceding five-year average for the same period. Comparison of March and February figures covering the total importation of coal from the United States and Great Britain showed an increase of 22 per cent. March imports amounted to 1,576,000 tons, while in February 1,281,000 tons was brought in. The March importations this year were 14 per cent greater than the five-year average for the month. During the month, 1,200 tons was imported from Great Britain. Total importations of all coal for the three months of 1924 was 4,090,000 tons, an increase of 8 per cent over the preceding five-year average for the same period. Imports of anthracite for March totaled 390,300 tons. This was 36 per cent more than in January and 4 per cent higher than the five-year average for the month.

Anthracite imported from the United States amounted to 389,100 tons, while 1,200 tons came from Great Britain during the month. The total amount of anthracite imported during the three months of 1924 was 1,021,600 tons, a decrease of 3 per cent from the five-year average for this period. Exports of Canadian coal for March were 32 per cent more than in February. The quantities were: March, 94,600 tons; February, 71,800 tons. Comparison of the March exports with the preceding five-year average showed a decrease of 54 per cent. Cumulative exports for the three months amounted to 249,100 tons, or 58 per cent less than the five-year average for the same period.

New Companies

The Oshaba Domestic Coal Co. has been incorporated in Birmingham, Ala., by E. J. Blackwood, E. R. Blackwood and others.

The Superior Briquet & Fuel Co., of Tacoma, has been incorporated with a capital stock of \$99,000 by A. F. Plant, A. E. Burkhalter and F. C. Hewson.

The New Beaver Coal Co. has been incorporated in Cleaton, Ky., with a capital stock of \$100,000, by John W. Price, John W. Basin and R. S. Lytle.

The Rainbow Coal Mining Co. has been incorporated in Montgomery, Ala., with a capital of \$10,000, by Homer F. Baird, Q. M. Selcer and others.

The American Coal & Power Co. has been incorporated in Denver, Colo., with 10,000 shares of no par value, by H. W. Newcomb, C. M. Tausig and F. W. Herres.

The McArthur Coal Co. Ltd., of Toronto has been incorporated with an authorized capital of \$40,000. The provisional directors are Wilfred C. James, Warwick H. Noble and Charles T. S. Evans.

Coal Service of Canada, Ltd., with an authorized capital of \$300,000, has been organized at Montreal and a Dominion charter granted. The company will engage in business as wholesale and retail dealers and operators. Montreal lawyers are mentioned as the incorporators.

Publications Received

U. S. Government Specification for Lubricants and Liquid Fuels and Methods for Testing. Bureau of Mines, Washington, D. C. Technical paper 323A. U. S. Government standard specification No. 2c. Pp. 89; 6x9 in.; illustrated.

Conduit Wiring, by Terrell Croft. Pp. 458; 5½x8½ in.; illustrated. Price \$3. A complete and practical explanation of modern practice in the installation of conduit wiring. McGraw-Hill Book Co., 370 Seventh Ave., New York City.

Handbook on Engineering (Steam and Electrical), by Henry C. Tulley. Seventh edition, fully revised and enlarged by James F. Hobart. Three volumes. Pp. 1,155; 5½x8 in.; illustrated. Price \$7.50. McGraw-Hill Book Co., Inc., 370 Seventh Ave., New York City.

Principles of Electric Motors and Control, by Gordon Fox. Pp. 492; 5½x8 in.; illustrated. Price 3.50. Explains the principles, construction and performance of all types of motors and controllers in commercial use, for both direct-current and alternating-current equipment. McGraw-Hill Book Co., Inc., 370 Seventh Ave., New York City.

Alternating-Current Armature Winding, by Terrell Croft. Pp. 352; 5½x8 in.; illustrated. Price \$3. Explains how to assemble and connect the new winding into the stator, how to determine whether or not it is feasible to reconnect a given winding for operation at a voltage, frequency, phase or speed other than that for which the machine is rated and how to make the reconnection. McGraw-Hill Book Co., Inc., 370 Seventh Ave., New York City.

Traffic News

Denies Lower Coal Rate On Gauley Branch of C. & O.

The Interstate Commerce Commission has denied an application by the Chesapeake & Ohio Ry. for authority to continue to maintain rates on bituminous coal from mines on the northern portion of the Gauley branch of the C. & O. to destinations in numerous states lower than from intermediate points on that branch.

Hearing on Coal Rates to Iowa Transferred to St. Louis

After two weeks of taking testimony in Des Moines, Iowa, Examiner Disque, of the Interstate Commerce Commission, late last week transferred to St. Louis, Mo., the protracted hearing on coal rates from Illinois, Indiana, Kentucky, Tennessee, Ohio, West Virginia and part of Virginia into Iowa. The hearing is to be resumed again in Des Moines some time in July. The State of Iowa and various associations representing coal consumers charge in their complaints that freight rates on coal into Iowa are excessive as compared to rates into other states of comparable distance from producing fields.

Dakota Lignite Rates Hang Fire

The Interstate Commerce Commission has handed down another of its split decisions in the North Dakota lignite case. The proposed increase in rates suggested by the railroads, of 40 to 50 per cent, was held to be unwarranted and the suggested rates cancelled. At the same time it was held that the old rates were too low, but there was lacking sufficient evidence to indicate what they should be. A suggested schedule of the examiner who conducted the hearing is named for consideration. This merely puts the whole question off for another complete hearing. It apparently accepts the suggestion that as lignite is of a lesser fuel value it is entitled to a lower schedule, but does not determine what that rate should be.

Mines on Greenbrier & Eastern Want New River Rates

The Interstate Commerce Commission is being urged vigorously by coal operators on the Greenbrier & Eastern R.R. to affirm its original findings which makes New River district rates applicable from their mines. The commission handed down a decision in this matter on Dec. 9 of last year. In this decision the Chesapeake & Ohio and other carriers were required to establish eastbound and westbound rates from the Greenbrier mines which are identical with those applying to mines in the New River district. In January, however, the Chesapeake & Ohio filed an application for a rehearing, which was granted by the commission. The appli-

cation for rehearing was made on the basis that inaccurate information had been furnished by the complainants. This has been denied by them. They contend that the coal mines on the Greenbrier & Eastern produce coal similar in character to the smokeless coal of the New River, Winding Gulf, Pocahontas and Tug River districts located on the C. & O., the Virginian, the N. & W., the Sewall Valley and the Kanawha, Glen Jean & Eastern.

It is contended, for instance, that the Virginians policy is to restrict the movement of coal to Eastern destinations, having built an impregnable rate wall at one end of its railroad and succeeded in forcing the flow of traffic to satisfy best its own revenue needs.

Obituary

F. Murray Olyphant, for forty years secretary of the Delaware & Hudson Co., died on June 17 at his home in Englewood, N. J. He was 68 years old. Among the many charities to which Mr. Olyphant had long given active support, the one that most deeply enlisted his sympathies, was the Jerry McAuley Mission.

Charles M. Lilly, of Beckley, W. Va., a prominent coal operator, was killed by a flash from an electric wire at Packs Branch last week. Born near Hinton, Mr. Lilly was 49 years of age at the time of his death. When a young man he went to work in the mines in Raleigh County and by constant work and perseverance won his way to the top. At the time of his death he was president of two large operating companies, the Four Vein company, at Lanark, and the Packs Branch company, at Packs Branch. He also had other large interests.

New Equipment

Splash-Lubricated Gathering Pump for Mine Use

The Columbus Gear & Pump Co. has recently placed upon the market the new gathering pump for mines shown in the accompanying illustrations. This machine is only 36 in. high, and consequently is well suited to installation in low coal beds. Its other dimensions are, width 30 in. and length 55 in.

This pump is built in three sizes,

Fig. 1—Side View of Pump

In this picture the valve-chest and yoke-case covers have been removed, showing the simplicity of the internal parts. The yoke case normally is kept half full of oil, thus affording effective lubrication to all parts within.

that is, with cylinders of 4-, 5- and 6-in. diameters, the length of stroke in all cases being 7 in. The capacities of the three sizes are respectively 50, 75 and 110 gal. per minute. The speed in all cases is 66 r.p.m.

Several somewhat unusual features are embodied in the construction of this pump. Thus, motion is transmitted from the crank to the piston rod by means of a crank block working within a yoke. The piston rod is thus given a true harmonic motion. This yoke reciprocates within an oil-tight case that is kept nearly half full of oil.

In the construction of this machine

Fig. 2—End View of Pump

This shows how the motor and control apparatus are mounted directly on the pump frame. Possibility of relative movement between these parts, such as might result in misalignment of the gears, is thus rendered remote.

a tip has been taken from automobile design. Thus shafts, crank pin and like parts are turned, case-hardened and ground affording members that fit perfectly and endure long wear.

Both motor and starter are mounted directly on the machine frame and thus in reality form an integral part of the pump. This machine is regularly made with a bronze-fitted cast-iron cylinder but may also be supplied with cylinder and valve chest of acid-resisting bronze.

Truck-Mounted Electric Welding Outfit

A new portable arc welder, said by the manufacturer to be designed to insure smooth and rapid deposition of metal with thorough penetration, delivers continuous power and permits rapid production, both with high current and large electrodes, as well as with low current and small electrodes.

This welder, made by the General Electric Co., is a two-unit set, consisting of a motor and a generator. The latter is self-excited, the current being regulated entirely by turning a hand-wheel on the generator. A self-adjusting, stabilizing reactor is provided, which automatically steadies the arc under all welding conditions. It can be used with any of the commercial sizes of metallic electrodes from $\frac{1}{8}$ in. to $\frac{1}{2}$ in. diameter. The voltage of the generator can be adjusted to suit the character of the work. High voltage for complete penetration on heavy work and low voltage to prevent burning through on light work are thus obtained at will. Many current values between 75 and 300 amp. can be obtained.

Among the operating advantages of this outfit are: an arc easy to start and maintain, roller-bearing wheels, holes in base for crane hooks and adaptability to long or short leads, for working close by or at a distance from the set.

Among the mechanical advantages are included motor and generator insulation designed to withstand severe operating conditions both with regard to duty cycle of the load imposed and general atmospheric conditions under which ordinary insulation fails. Bearings are waste-packed and oil cannot be spilled if the set is tipped when being moved.

This welding generator is a two-pole, self-excited, constant energy, single-operator machine with a dual magnetic circuit designed to operate at 60 volts open circuit and 20 to 25 volts under

Meters and Gages Give Direct Indication of Power Plant Operations

The multi-scale indicator at the top of the panel tells at a glance just how every device in the plant is functioning. On the charts at the bottom, records are made for comparative data.

load. It is rated at 200 amp. for continuous service, 250 amp. for one hour and 300 amp. for short periods. The motor is a standard 10-hp. unit. The complete set has three bearings, the two units being close-coupled by a solid flange coupling. All parts, including generator, motor, generator control panel, motor starter and stabilizing reactor, are mounted on a welded structural steel base of rigid construction and light weight.

The assembled unit is about 63 in. long, 29 in. wide and 47 in. high and weighs about 1,600 lb.

Improved Steam-and-Air-Flow Recording Meters

It has long been known that boilers can be operated efficiently only when suitable recording meters are continually in operation to check up the various processes of converting latent heat energy in the coal to mechanical or electrical energy. The designing engineers of modern power plants have appreciated the desirability of incorporating certain features in all indicating and recording instruments. The Bailey Meter Company, of Cleveland, Ohio, has recently placed on the market several new type flush-front meters and gages. These instruments are designed for panel-board mountings, and are so constructed that the meter casings are behind the panel.

A double flush-front meter, to be used with a boiler equipped with an economizer, is one of the most interesting of this new line. Steam flow and air flow are recorded on the left-hand chart while temperatures of the feed water entering and leaving the economizer are recorded on the right-hand chart. The multi-pointer gage above this meter is suitable for installation on a boiler fired with a forced draft chain grate stoker. It indicates wind-box pressure, fire compartment pressure, firebox draft, and chimney draft.

Arc Welding Outfit

Current regulation easily may be obtained by a slight turn of the hand-wheel. A stabilizing reactor automatically steadies the arc under all welding conditions. Either high or low voltage can be provided so that all welding may be done with current of the required pressure.

Runs on Picking-Table Refuse

A power plant that is charged for refuse from the picking table at clean-coal rates uses that refuse and screenings for generating the steam by which its power is obtained. Yet it gets its power for 1.6c. per kilowatt-hour and is running only at about one-half load. This story which every one will want to read will appear next week in *Coal Age*. Perhaps you will desire after reading it to put your picking-table refuse in your boiler room, to get such a tidy figure for this waste material and to obtain your power at low figures like these. Maybe you might improve your coal if you could afford to pick it with a lavish hand as it is done at this plant.

Hope for Low Accident Rate

An article deals with speed in coal extraction and says it may prove as economical of life and limb as it is profitable from the viewpoint of lower costs and conservation of coal.

How Uncle Sam Manages His Leases

The Bureau of Mines makes regulations for Government leases. An article next week will give some interesting details regarding this regulation and supervision from the man who has charge of the latter.

POWDERED COAL

Rigid Technical Control of metallurgical operations and uniform production are vital to the manufacture of the products that have established the O-B name. That is why the most modern and efficient methods in utilizing fuel are employed in the O-B Plant. Powdered or pulverized coal plays an important part in supplying high quality and uniform grade O-B Products to you.

(Top) Exterior view of the O-B pulverizing plant at Mansfield. Note the pipes for transporting the powdered coal from pulverizing plant to points where utilized.

(Center) One end of the pulverizing plant showing dried coal storage, pulverizing mill, pulverized coal storage and distributing system.

(At left) Pulverized coal burning unit on the 20-ton melting furnace in the malleable iron foundry at Mansfield.

Before You Speed up Your Main Fan to Get More Air-

REMEMBER—To get twice the volume your fan is now doing, you must run it twice as fast, and this takes **EIGHT TIMES THE HORSEPOWER.**

A Jeffrey Universal Blower, installed to boost the current, will immediately improve your conditions at the working faces, while the work of improving the air courses is going on. Ventilation cost will be kept at a minimum, at the same time assuring efficiency from the miners.

Example:—Assume the main fan has a normal capacity of 80,000 C.F.M. at a certain speed, and the mine is divided into four splits, each requiring 20,000 C.F.M. The resistance in one split will only pass 10,000 C.F.M. Speeding

up main fan to get the additional 10,000 C.F.M. would be uneconomical because it would require double the fan speed, and the placing of regulators on the other three splits, requiring more than four times the horsepower.

The correct and economical thing to do is to place a Booster fan on the split requiring the additional volume and not touch the main fan.

Blowers and Boosters are built in sizes from 8 in. to 5 ft. 0 in. diameter. The smaller direct connected units are principally adapted for use with flexible canvas tubing for ventilating dead ends, entry driving, sinking shafts, driving tunnels, conveying rock dust, ventilation of underground hospitals, etc. All sizes carried in stock.

Why Ford is the Overwhelming Choice in the One-Ton Field

No more striking evidence of the high regard of truck operators for Ford performance and economy can be offered than the fact that 78% of all trucks in the one-ton class are Fords.

Only outstanding proof of exceptional value could have brought this dominant preference.

Only by demonstrating the utmost dependability and proving its ability to save under any and all conditions could this Ford One-Ton Truck have gained and held the good will

of so many operators year after year.

Lowest in cost, easiest to handle and simplest to maintain the Ford worm-drive Truck is the standard light-delivery unit of American business.

This all-purpose rapid-delivery unit is adaptable to all seasons and conditions of travel, and to the economical haulage of a wide variety of products.

Over 33,000 Authorized Ford Service Stations assure quick, easily available service everywhere.

Sullivan Air-Electric Drilling Rigs

**Save Time
and Labor in
removing
Rock under-
ground**

Rock Fault Pierced Quickly

At an Ohio mine, a *Sullivan W'K-26 Motor Driven Compressor*, size 8x8, and a *Sullivan Rotator Hammer Drill* drove an entry through a rock fault in hard conglomerate.

The Compressor provided air at 80 pounds to the square inch. Holes were drilled to a depth of six feet in the center of the heading, and 2 spotters, one on each side, to a depth of four feet.

With this outfit 81 feet of holes were drilled in three hours' time.

This rig did as much work in two hours as was formerly done in eight hours with the old style breast auger. Just an instance of one of many kinds of useful work you can do with a Sullivan "WK-26" Compressor.

Changing Conditions Necessitate Redesign of Mine Cars

In the days of easy competition, coal costs could stand the extra tax due to wastefulness, but in these days of sagging markets only low cost coal mines employing economical methods can hope to survive.

Increased production usually results in lower costs, and one way to boost production is to install cars of greater capacity. Numbers of companies are taking this way out of their difficulty, even though it often requires an entirely new design of car, usually of the low, wide and long barge type for use in rotary dumps.

An operator recently told us that "these newer designs of mine cars with greater capacity make Hyatt bearings even more imperative. We used them under our old cars with complete success and couldn't get along without them now."

Many companies are throwing out entire lots of old cars, making the replacement with Hyatt bearing equipment especially designed by one of the many manufacturers who build Hyatt bearings into their mine cars.

If your production is dwarfed by small cars you can make it grow by having new cars designed which will carry more coal. And if equipped with Hyatt bearings they will have a lower power consumption than the old, small, plain bearing cars.

Keep Them Rolling

Trouble with your mine car wheels goes hand in hand with poor lubrication. Correct the cause and the trouble will vanish.

The cause is chiefly a type of lubricant that will not stay in the wheel bearings; the remedy is a semi-fluid grease of unchanging density. It should be of high lubricating value, impervious to water, and free from ingredients that clog and cake.

Such a lubricant is found in Keystone Grease No. 119 density medium, intended for equipment in good condition, and Keystone Grease No. 119 density heavy and Keystone Grease No. 119 density extra heavy for worn equipment.

Hyatt Roller-Bearing mine car wheels will operate for six months or more on one application of Keystone Grease No. 119 heavy. For solid roller-bearing mine car wheels Keystone Grease No. 2 density is recommended.

Write and ask us what our guarantee and our service department will do for you.

\$60.00.

Holes in a Hurry With This New "Van Dorn" Haffinch

An Electric Drill that has more "pep per pound" than any other drill on the market.

Mines everywhere will welcome this light weight, reasonable priced, half inch, "Van Dorn" Electric Drill that has more power and delivers more holes per man — per tool — per day than any universal electric drill ever offered to this field.

Haffinch is a wizard for speed on maintenance and repair jobs to mine cars, pumps, hoisting equipment, tipples, conveyors, crushers and other odd jobs without number.

You will find this light weight tool a time saver and a money maker for all "hurry up" jobs around the mines and a fine addition to the larger "Van Dorn's" that you have possibly used for 20 years.

A "Van Dorn" representative will welcome an opportunity to demonstrate it to you.

Mine Examination Questions and Answers

By James T. Beard, Senior Associate Editor, Coal Age

Formerly Principal School of Mines, International Correspondence Schools.

Practically every question that has ever been asked by a mine examining board in recent years is in these three books. The answers and illustrations are wholly original and, taken as a whole, cover every important phase of coal mining practice.

Mr. Beard has done his work so thoroughly and so well that the books will be found of the utmost value as practical reference volumes on everyday mine operation as well as aids to passing examinations.

In other words, their usefulness does not end when they have passed a man through an examination. Every time a problem in mine operation comes up these books will furnish a practical solution to it.

Examine the books for 10 days free

Send us your name and address so we can mail these books. You can examine them for ten days without obligation. We pay all the postage.

If these books are what you want you can keep them by paying \$1.50 in ten days and then only \$2.00 a month until \$7.50 has been paid.

Make your summer pay well—get your coupon off today.

SILENT CHAIN DRIVES

Morse Silent Chains driving circulating pumps from motors.

Wherever efficient power transmission is demanded, Morse Chain Drives are used

Morse Chains deliver the maximum power from the motors to pumps, and other driven machinery, smoothly, noiselessly, and with the greatest economy.

Power users in every branch of industry have learned they can rely on Morse Chains to perform their allotted task.

Morse Silent Chain Drives have won their merit mark by trouble-free service; flexibility; freedom from slippage; and ability to transmit 98.6% power.

Morse engineers will gladly help plan a drive that will save power, worry and expense.

The Reading engineers became anxious over these stoppages and after a thorough investigation decided that many of the breakdowns were due in part at least to the operator's starting the pumps before they were properly primed and continuing the operation of the pumps after the sump was lowered. Realizing that any attempt to operate the pump not properly primed was disastrous to the pump, it was decided that to make a really successful centrifugal mine pumping plant, the several manual operations should be made automatic, thus eliminating the human element in the vital stages of operation.

Extract from
Coal Age—9/13/13

“eliminating the human element in the vital stages of operation”

This is exactly what the Hazleton Automatic Pumping and Control Unit does. And it was built in answer to a vital need.

This Hazleton Pump is primed, started, protected and controlled automatically.

When the water rises to a predetermined height, a float, in connection with a vacuum breaker, rises, effecting the closing of an electric control circuit. When this circuit is closed, the priming pump starts, opening the priming valves. When the priming is completed, the centrifugal pump starts. After the water is pumped down to a predetermined level, the electrical control stops the pump.

Protective devices, too, take care of any possible emergency. By means of these devices, the operation cannot go on if there is any danger of leakage in the pipe lines or any danger of the pump losing its water.

Thus with the Hazleton Automatic on the job, disasters due to human mistakes or forgetfulness are eliminated once and for all.

Complete particulars on the operation of this new revolutionary pumping unit will be sent you by return mail, along with Bulletins on our entire line of Centrifugal Mine Pumps, Priming Pumps and Valves, Vacuum Breakers, Check Valves, etc. Let us know where we can reach you.

BARRETT, HAENTJENS & CO., HAZLETON, PA.

Bethlehem Mine Specialties

Heavy Duty Switch, Design 396

BETHLEHEM HEAVY DUTY SWITCH is fitted with extra heavy plates and braces—practically corrosion proof—will stand unlimited abuse—derailments eliminated—lengthens tie life—maintenance expense wiped out—plates and braces last indefinitely—switch points cost no more to renew than other kinds.

No. 2 Bethlehem Steel Mine Tie

BETHLEHEM MINE TIES are in one piece—no loose parts to mislay—clamping clip quickly turned to position with hammer—track always to gage—extra ties can be added or taken out without disassembling track

—maximum head room—longer life than wooden ties—greater strength by increased weight over earlier Cambria designs—can be used many times—popular with miners.

Paralled Throw Switch Stand, Model 1217

BETHLEHEM PARALLEL THROW SWITCH STAND, MODEL 1217, is adjustable for any throw—lever throws parallel to the track—when in normal position, lever is on “dead center” and switch is positively held—only 3 in. high—only 3 moving parts—no bolts—can also be furnished with spring rod.

Solid Cast Frog, Design 289

BETHLEHEM SOLID CAST FROG, Design 289, is made either of carbon, or manganese steel—strictly one-piece construction with no rivets or plates to work loose—flange bearing feature makes for smoother riding and reduces wear on wing rails and point—unbreakable and easy to install.

Bethlehem also manufactures heavy track work for steam Railroads, such as Rails, Guard Rails, Switch Stands, Crossings, Tie Plates, Fish Plates, Splice Bars, Solid Cast Frogs, Special Track Work, etc.

Track Equipment for Mine Service

TIREX Cord Cuts Drilling Costs

Economical, efficient drilling depends largely on the flexible cord upon which the tool must depend for power. Cord failures mean idle tools, idle men and expense of repairs. Even a high grade tool will make a poor showing when it is frequently laid up for cord repairs or replacement.

TIREX costs less than ordinary cords because it lasts so much longer. The conductors are flexible and are adequately insulated with a high grade rubber compound. The outer covering is a 60% rubber sheath having the wearing qualities of a first class tire tread. It is almost wearproof.

TIREX costs less than ordinary cords because it lasts so much longer.

10 Innings—No Errors!

A ten-inning ball game with no errors is considered a remarkable performance in the world of sport.

The *ten year* record of dependable mine pumping service established by the Deming pump shown in the view above is not unusual. This Deming "Neptune" Double-Acting Piston Pump was installed ten years ago in the mines of the Valley Smokeless Coal Company, Johnstown, Pa. It has been in 12-hour-a-day service ever since, working under the worst acid conditions, and its owners report *it has never given any trouble!*

MINE PUMPS

Like giant hands, restraining~

Always on guard, never apparent, the restraining rings stand behind the normal governing devices in the Westinghouse Small Turbine for generator drive, prepared for instant action and providing an insurmountable factor of safety against overspeeding due to motorizing of generator or other accidental causes. This splendidly characterizes the high state of perfection to which the small Westinghouse unit has been developed.

Ready for full capacity?

Oxweld Portable Outfit

The Ambulance of Industry

THE oxy-acetylene welder's portable truck outfit made by Oxweld has frequently been called the ambulance of industry. By means of this little truck a complete oxy-acetylene welding and cutting outfit with cylinders can be transported easily and rapidly to any part of your plant. Repairs can be made quickly and economically and long and expensive shut-downs avoided. Frequently parts may be repaired without dismantling the machine, and nearly always repairs can be made on the spot, thus avoiding the necessity of carrying broken parts through your plant.

If you wish to save money on plant maintenance, send for the nearest Oxweld Resident Engineer.

IS YOUR PLANT ready for full capacity production?

Have your engineers and master mechanic seen to it that every piece of machinery is in operating condition? You realize that periods of part-time or shut-down are ideal for making repairs.

Oxy-acetylene welding will repair many machines at a fraction of the cost of replacements. Oxy-acetylene welding will enable you to reclaim many broken or rejected parts. Oxy-acetylene cutting will help you make changes rapidly and economically.

If you use Oxweld welding and cutting apparatus, Oxweld engineers and fieldmen will gladly show you how the oxy-acetylene process can help keep your plant equipment in working condition at all times. Send for free book, "Oxweld Can Do It." It illustrates many applications.

WELDING AND CUTTING APPARATUS

WORLD'S LARGEST MANUFACTURERS OF WELDING AND CUTTING EQUIPMENT

Hard pulls and rough going? No Matter!

Increasingly heavy loads and rapid acceleration on Rope haulages and hoists—

The grinding and tearing effect of hard slope conditions on Wire Rope as it pounds the rollers and drags on the ground—

The severe bending stresses set up as the Ropes run over the small drums and sheaves that are of necessity used on some operations —

Problems such as these are successfully solved by HAZARD Wire Rope engineers.

Constant research work—laboratory selection of raw material—finest wire drawing and rope making skill, combined with the scientific adaptation of the proper Wire Rope to each operation on an engineering basis:—

That is why HAZARD Wire Rope will so far outwear the average rope, and why it is most economical.

Let us look into your most difficult Wire Rope operations and show you how to cut down your ton costs.

HAZARD

Electrical Equipment

A Bank of 500 kv-a. G-E Transformers stepping down 6000 volts to 440 volts at a Pennsylvania coal operation. G-E Lightning Arresters protect the installation. Other view shows G-E Oil Circuit Breakers in the Mine Power House supplying this Receiving Station.

Reduce Distribution Losses with Modern Transmission Equipment

High-tension power distribution has rightly superseded direct-current power lines at modern coal operations, because of the well-known higher efficiency of alternating-current distribution.

The efficient transmission of energy from a central coal-mine power station to several mines requires modern, efficient, *dependable* equipment.

G-E Oil Circuit Breakers, Transformers, Lightning Arresters and other apparatus making up complete switching equipment insure continuity of service and the highest possible operating economy.

Specify "G-E".

General Electric Company
Schenectady, N. Y.

GENERAL

for Lower Costs per Ton

Automatic Sub-stations Maintain Power Supply and Increase Production

Direct-current mining equipment must have proper voltage to operate efficiently at full capacity. G-E Synchronous Motor-Generator Sets, Converters and Switchboards—or a complete G-E Automatic Sub-station

- improves power-factor to reduce line losses and make more power available.
- keeps voltage normal, which speeds up mining machines and locomotives
- insures against tie-ups and thereby helps you increase tonnage with present equipment.

The automatic sub-station is an established factor in reducing operating costs per ton.

G-E Automatic Synchronous M-G Set in a surface sub-station, "pepping up" direct-current voltage and correcting lagging power-factor.

ELECTRIC

Don't Buy Grease

DID you ever look at it in that way? Correct lubrication means not only longer life, less friction, and cool bearings, but an actual reduction in the horsepower consumed. This represents a great saving to Industrial Plants.

WAVERLY GREASES will show a saving for anyone who will make a trial. Time and again we have actually proven to Mine Owners, Paper Mills, Rolling Mills, and all users of grease that WAVERLY GREASES, properly applied, will materially reduce power consumption.

It will cost you nothing to make this same test. We will ship you a barrel of grease which you may return at our expense and at no cost for the grease used if it does not perform satisfactorily according to our guarantee.

There is a Waverly Grease for every kind of machine—a grease that will save you horsepower. Don't buy grease—buy Horsepower.

Send for the Waverly Industrial Lubrication Booklet. It gives precise recommendations for oil and grease lubrication of all standard machines. Only book of its kind in print.

Counting three and one-half millions of property dollars every day

We are frequently asked for the reasons why American Appraisals occupy their supreme position in the estimation of American business.

The outstanding reasons are the endeavor of The American Appraisal Company to make valuation work a science. As a result of its intensive and long experience, every working day three and a half millions of property dollars are now counted by means of American Appraisal Service.

This intensive daily experience deals with properties in every state in the union and abroad. Throughout these twenty-eight years of exclusive appraisal work American Appraisals have pioneered important advances in the making and application of appraisals for insurance purposes.

Some of the factors in this experience that are of particular interest to the business man in connection with fire insurance, have been recently embodied in our monograph J-6, "When Insurance Insures and When It Doesn't."

Mechanically Cleaned Semi-Bituminous Coal

We have installed at some of our mines and are equipping the remainder with a "PNEUMO-GRAVITY PROCESS," patented by us, by means of which any impurities are largely eliminated from our coals.

This process successfully *cleans from finest Slack to Lump* and the resultant product can be loaded together as R/M, or separately as Lump—Nut and Slack.

It is entirely and continuously mechanical in its operation, thus avoiding the human element, which has, heretofore, prevented the continuous and uniform elimination of impurities so absolutely essential in the maintenance of a high standard of preparation.

As no water is used in this process, as contrasted with wet washing methods, no additional freight charges are incurred by reason of excess moisture, nor difficulty encountered in unloading frozen coal during

winter months. The saving in freight and the increased boiler efficiency obtained, due to the low ash and sulphur content of "PNEUMO-GRAVITY" coal, is a net saving and of such importance as to warrant the scrutiny and consideration of every buyer of steam coal.

Produced in Central Pennsylvania Field, from mines in Clearfield, Cambria and Indiana counties; developed and mechanically equipped for an output of four million tons annually.

Shipping to New England and Middle Atlantic States, via New York Central Railroad, Pennsylvania Railroad, and their connections.

Tidewater deliveries at Canton Piers, Baltimore, Md., Port Richmond and Greenwich Piers, Philadelphia, Pa., Port Reading, South Amboy, Elizabethport, Port Liberty, and Pier 18, Jersey City, New York Harbor.

Adaptable to any
standard scale

The Correct weight— for every car

Careless, slipshod hand weighing at the tippie is an economic waste which means loss to both miners and operators.

The Streeter-Amet weighing and recording attachment eliminates these losses. It records the *correct* weight instantly. Miners are better satisfied because this machine cannot fail to record all tonnage mined. Operators know it eliminates all overpayments. Write for details.

MARION MINING
MACHINERY

for better work in mining coal

YEARS of study devoted to the coal miner's problems combined with a great amount of chemical research, constant experimentation and exhaustive field tests, have resulted in the development of the Atlas line of Coalite Permissibles.

Atlas now makes two permissibles that are stronger on a weight basis than any other permissible on the market. The company also makes one that is the weakest on the market, and one that has a lower velocity of detonation than any other permissible. Thus, the Atlas line of permissibles covers a wider range of desired characteristics than any other line of permissible explosives—a range that will meet the conditions encountered in any kind of coal mining.

Write for
a copy of
the new
Atlas
catalog.

Let the Atlas Service Man help you in determining what grade of Coalite is best adapted to the requirements of your work.

STRAINS only increase the hold of the Sure-Grip Trolley Clamp on the wire. They hold at all times and under all conditions. They eliminate all troubles and tie-ups due to sagging wires, thus speeding production.

Sure-Grip Clamps are as simple as they are efficient. They have no rivets, bolts, screws, springs or pins. They are easily put up and easy to take down. They are rust-proof.

36 Cents Per Year Per Starter For Maintenance

Type "SS" Automatic
Motor Starter

¶ For 200 type "SS" Automatic Motor Starters installed on mine pump motors over a period of two years, there was purchased only \$72.44 worth of repair parts during that time. The average length of time these Starters had been in service was one year. \$72.44 divided by 200 is 36 cents.

¶ How does this compare with your maintenance cost?

¶ Might it not be worth while considering the type "SS" Automatic Starter the next time you are in the market for a starter for your pump motors?

Maintenance cost on type "SS" Automatic Motor Starters is low because they are built of good stuff and plenty of it to begin with.

Bulletin 500-A describes this starter in detail.

Records Speak Volumes

The unusual qualities of Caldwell Cypress Tanks are proven by their enviable records in all sections of the country. Perhaps this is largely due to the fact that of all woods, cypress is the one which lasts best outside its native climate.

Thirty years' experience in building tanks enables us to couple this remarkable tank wood with workmanship and design that ensure the maximum of tank satisfaction.

Have You the Right Type of Locomotive?

TRANSPORTATION costs will always be high unless the locomotives employed are perfectly suited to mining conditions.

The Shay Geared Locomotive meets every haulage requirement of the mining and stripping operator.

The Shay works on lighter rail and rougher track than a rod-driven engine of the same power. The Shay hauls loads up grades that would stop a rod engine. The Shay stays on the track at curves that invariably derail the rod engine.

Shay Geared Locomotives have many money-saving features that will help you reduce transportation costs. Write for details.

REID Safety Frog Cast In One Piece

Trucks pass over the Reid Safety Frog as smoothly as over continuous rail. There is no jolt and consequent damage either to frog or rolling stock. This saving of wear and tear on cars alone is but one reason for the superiority of these safety frogs.

It is as easy to lay the Reid Safety Frog as it is to lay a rail. The frog is all in one-piece and once in place, cannot become loose or twisted out of line.

We now make these frogs with rail extensions for bolting to the rails.

Send for complete description of this valuable equipment.

LOBDELL Car Wheels

Built for Service

The unusual wear resisting quality of Lobdell Wheels is due to the special Lobdell Heat-treating Process. It builds strength and long service right into the wheel. It makes the thread hard and resistant to wear, the spokes and hub strong and resistant to strains and shocks.

A smooth-rolling wheel reduces the wear on locomotives, cars and track, reduces maintenance and repair costs—it pays for itself many times over. That's why it's real economy to invest in Lobdell Wheels.

*Begin Now—

LOBDELL CAR WHEEL COMPANY

Established 1836

WILMINGTON, DELAWARE.

LOBDELL
Mine Car &
Locomotive Wheels

OHIO Grease

HOT BOXES

—are unheard of when wheels are lubricated with Ohio Mine Car Grease. Suitable for wheels of every kind. The one ideal lubricant for reservoir or cavity type wheels whether plain, roller or ball bearing.

Unaffected by weather. Low cold test —long lasting—the perfect lubricant for mine car wheels.

A free bulletin and generous sample will be sent free on request.

That Haul From Tipple to Siding—
A one man machine and a steady movement of coal when using the
AUTOMATIC AERIAL TRAMWAY—
Assures economical operation and takes you a long step towards profits.
Put your hauling problem up to us.

Interstate Equipment Corporation
25 Church Street, New York City

The illustration below shows the "Cincinnati" Type "E" switch stand. This is a parallel throw stand and is a popular type.

Put it up to us

One of the things which have contributed to the high standing of "Cincinnati" Track Equipment throughout the coal fields is the service behind it. No matter what your requirements or problems "Cincinnati" experience and "Cincinnati" facilities are at your service.

You can depend upon "Cincinnati" equipment to provide safety and facility for your haulage year in and year out at low service cost.

A track-shifting kink

When you shift the track, call the welder. Go over the bonds. Be sure of the welds. Good bonds are purely in the jewelry class unless they are properly welded to the rail. The secret of good welding is a good welder. Here's one that has made good—

AJAX Electric Arc WELDER

No wonder. It's the only welder of anywhere near its size and price that will always give sufficient amperage for a good weld even where the line voltage drop is 50%. Type IND 300-volt size weighs 55 lbs. and type RWY 600-volt size 150 lbs. Rugged, everything accessible, well ventilated—and inexpensive. You'll like the rest of the story too. It's in the Ajax Bulletin. Want it?

Railway Trackwork Co.

3132-48 East Thompson Street, Philadelphia

Longer Service—Less Lubrication

THE SENSENICH TRUCK

Insures light running and saves power. Made with enclosed hub wheels in which a U-form bent steel pipe is cast to secure lubrication in all positions. There is no chance for oil passageways to become clogged. The wheel is held in place on the axle by a malleable iron lug that fits in a groove. The axle itself is also free to revolve in stationary boxes. Hyatt Roller Bearings can be furnished on request. Write for details.

Irwin Foundry & Mine Car Co., Irwin, Pa.

Switch Stand With Spring
Connecting Rod

You might think it does, but it doesn't

Were you to see a stock of Central Track Equipment—frogs, switches, switch stands, crossings and room turnouts—you'd probably be impressed with the high quality of the various units. Upon examination you'd discover structural and operating features which would impress you tremendously. And you might think that naturally such equipment costs more than the ordinary kind—you might think it does, but it doesn't!

Where the Service is Hardest Ball Bearings on Mine Locomotive Motors

THE rough jolts and jars to which this mining locomotive is subjected in daily service have little effect on its efficiency and dependability. This freedom from costly delays is due in no small measure to the use of Skayef Self-Aligning Ball Bearings on the motors, which require a minimum of inspection and maintenance.

Showing no discernible wear, even after years of hard service, they keep motor armatures in correct position throughout the life of the locomotive. Dust and grit, which would soon cause rapid destruction of plain bearings are effectively excluded by sealed housing which also prevent lubricant leakage.

BECAUSE "Reading" has a siliceous slag content it resists the corrosive action of acid drainage water two to three times longer than steel pipe; and because the 100% wrought iron of all Reading Pipe withstands the vibration of high pressure pumps it is the pipe *best adapted* to the particularly severe work in mine operations.

MALLORY COAL COMPANY

MALLORY,
WEST VIRGINIA

April 19, 1924.

JNO. T. SYDNOR,
GENERAL SUPERINTENDENT

Link-Belt Company,
Huntington, West Va.

Gentlemen:

Complying with your request through Mr. McTigue.
We wish to advise that approximately one year ago
owing to the very severe cutting conditions which were
encountered in our Number 3 Mine where it was necessary
to put a ----- Machine into a very hard bend of blue
slate we decided to try your Link-Belt Improved Coal
Cutting Chain. Previous to the installation we had a
great deal of electrical trouble in burning out field
coils and armatures. This was eliminated by your chain
approximately 50%. In addition to this the bits are
standing up a great deal better and during the last year
we have only bought two mining machines cutting over 200
tons each day, 200 bits where difficult cutting is en-
countered. We have no hesitancy whatever in recommending
your chain.

Very truly yours,

Jno. T. Sydnor
GENERAL SUPERINTENDENT.

Mining Interruptions Reduced 50%

Called upon to perform particularly severe work at the Mallory Coal Company's mines a year ago, Link-Belt Coal Cutting Chain did it, and has been doing it since. The performance in this case is typical of the chain's work elsewhere—doing the hardest job, with maximum efficiency. Your specific or ordinary cutting problems will be solved upon the installation of Link-Belt Coal Cutting Chain.

Some Features of Link-Belt Coal Cutting Chain:

1. Cutting Bits are self-sharpening. One set will, without redressing, cut six times the amount of coal cut by any other chain.
2. Requires less motive power to operate.
Cuts, instead of scraping.
3. Coal cuttings contain a much larger percentage of pea coal and less dust.
4. Reduces loss of bits due to set screws working loose.
5. Reduces cost of redressing cutting bits, by about 17 per cent.
